CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 | New York, January 3, 1923 | Number 1

Chemical & Metallurgical Engineering
is the successor to *Metallurgical and Chemical Engineering*, which, in turn, was a consolidation of *Electrochemical and Metallurgical Industry* and *Iron and Steel Magazine* effected in July, 1906.

The magazine was originally founded as *Electrochemical Industry*, in September, 1902, and was published monthly under the editorial direction of Dr. E. F. ROEBER. It continued under that title until January, 1905, when it was changed to *Electrochemical and Metallurgical Industry*. In July, 1906, the consolidation was made with *Iron and Steel Magazine*, that had been founded 8 years previously by Dr. ALBERT SAUVEUR. In January, 1910, the title was changed to *Metallurgical and Chemical Engineering*, and semi-monthly publication was begun Sept. 1, 1915. On July 1, 1918, the title was changed to *Chemical and Metallurgical Engineering*, and weekly publication was begun Oct. 1, 1919.

Dr. E. F. ROEBER was editor of the paper from the time it was founded until his death on Oct. 17, 1917. After a brief interim he was succeeded by H. C. PARMELEE.

The staff of *Chemical and Metallurgical Engineering* comprises: H. C. PARMELEE, editor; ELLWOOD HENDRICK, consulting editor; ERNEST E. THUM, associate editor; J. S. NEGRU, managing editor; A. E. BUCHANAN, JR., CHARLES N. HULBURT, SIDNEY D. KIRKPATRICK, R. S. MCBRIDE (Washington, D. C.), GRAHAM L. MONTGOMERY, CHARLES WADSWORTH, 3RD, ALAN G. WIKOFF (Chicago), assistant editors.

The Hopeful Outlook

THE truth of the old adage that hope springs eternal in the human breast has been given fresh point and emphasis in the spirit of optimism with which the world has abandoned the old year and turned to the new. Nineteen-twenty-two has gone; and good riddance, say we all. The new year is at hand, fresh, promising, hopeful, and we welcome its opportunities as we do the next hole in golf after a particularly atrocious score. Another chance! A new opportunity! A clean sheet! Well, what shall be writ upon it? For 8 long years we have courageously faced a new beginning on January first, and December thirty-first has seen us dejected at failure and discouraged over the poor accomplishment. What reason is there now to believe that this year will yield us any better fruit and leave us with a greater degree of satisfaction?

First, there is increasing evidence that the United States is discovering Europe. Even irreconcilables who 3 years ago shouted their opposition to participation in the tangled affairs abroad and determined for us a policy of isolation that has all but wrecked international trade and finance now fervently declare that the economic distress of Europe is an American problem and that we must give aid in our own selfish interest. We name no names, being content to rejoice in an eleventh-hour conversion. Nothing, in our estimation, could so brighten the outlook for the whole world as a definite plan for the United States to participate actively in the study and solution of Europe's economic and financial problems. No partisan or personal motives should be allowed to hamper the President in his laudable plans; rather should he be strengthened in the knowledge that this country is now as ready to serve in restoring peace and prosperity as it was to enter the war in 1916. Time to create national sentiment was the essence of both situations; and it has been accomplished now as it was then.

Next, in the words of ELIHU ROOT, we are coming "to recognize not only our rights as citizens, but our duties," thus phrasing in a single sentence the quality of leadership that the world needs today. A quality, too, that is recognized far more clearly by engineers and business leaders than by those engaged in diplomacy and statecraft. Political parleys have failed miserably to bring men closer together, because they have been concerned more with rights than with duties. The problems of debts, disarmament and finance have been approached and regarded as though their amelioration was a matter of bookkeeping, of barter and trade, when as a matter of fact their real solution lies deeper in the moral and spiritual realms of international good will and desire for peace. Germany must cease her hating and France must cast out her fears.

Finally there has developed during the past year a respect for economic law that augurs well for the American business man. Much of his instruction may have been weak and immature, but economics has registered with him, and he is more disposed to base his actions on economic principles. In a few cases sound economics has even supplanted political expediency, thus giving an earnest of the heights that can be reached.

With Europe peaceful and under reconstruction; with a clear recognition of our duties as well as our rights as citizens; and with business at home on a sound economic basis, we can finish the year nineteen-twenty-three with a feeling of work well done. Let us hope it may be so! Man is essentially an optimistic animal. It would be inconceivable deliberately to look forward to failure.

A Stitch In Time

SOME WEEKS AGO we announced the appointment by the Assistant Secretary of War of a representative group of men in the chemical industry to co-operate with the War Department in its plans for preparedness against a national emergency. Back of this announcement is a well-organized and systematic campaign in the department to anticipate its varied needs for the national defence and at the same time to ascertain the industrial capacity of the country to meet those needs. The Surgeon-General's office recently announced a similar survey of industry. The thought behind this activity is a commendable desire to avoid the frantic haste and extravagance in the mobilization of industry that characterized the first year of our activity in the late war.

The Assistant Secretary of War is charged by law with the "supervision of procurement of all military supplies and all other business of the War Department pertaining thereto and the assurance of adequate provision for the mobilization of material and industrial organizations to war-time needs." Naturally this gives the Assistant Secretary a deep and abiding interest in the chemical industry, because, as he aptly stated in a recent issue of the U. S. Army *Recruiting News*, "Practically all modern warfare is chemical warfare." This, and much more to the same point, is a refreshing and practical appreciation of chemistry on the part of the War Department. Realizing its dependence upon peacetime industries for the national defence, the government understands that the more trained chemists there are in various branches of industry the more talent and ability will be available in emergency No one will accuse the War Department of desiring to make war. Its present activities are highly businesslike as long as we maintain a War Department and charge it with the national defence.

Recovery in Steel Production

IN RETROSPECT it may seem easy for steel production to have increased by more than 75 per cent from 1921 to 1922, but it is not difficult to recall that a year ago it required some courage to predict any very great increase in production until "fundamental conditions" should be greatly improved. Judgment a year ago, moreover, was warped by the fact that with a moderate improvement in steel demand in the autumn there had come a sharp decrease in December. It now appears that the tapering off in demand at the end of 1921 was due to buyers being fearful of inventory, for before the end of January steel production had fully recovered its loss.

Production of steel ingots in 1922 was about 34,000,000 tons, which is a large or small tonnage according to the viewpoint. It was large by comparison with production in the calendar year 1921, being more than 75 per cent above the 19,224,084 tons produced in that year, and it was also large from the viewpoint of operations in December, 1921, which represented ingot production at a rate of less than 20,000,000 tons a year. On the other hand, the 34,000,000 tons of 1922 looks somewhat small by comparison with the record output, 43,619,200 tons, made in 1917, or the 40,881,392 tons made in 1920.

Comparison of steel production with "capacity" must be made with reserve and with qualifications. Prior to November, 1916, the steel industry was practically always able to operate at its "capacity" when it had the requisite orders. Since then it has never so operated, although capacity as properly estimated is based upon the actual output in 1916 plus a conservative allowance for new construction. There have been strikes, railroad congestion and other factors every time the mills were filled with orders. The capacity may be estimated at between 50,000,000 and 55,000,000 tons a year, and on this basis the 1922 production represents a working rate of only about 65 per cent.

The steel industry prospered much less in 1922 than would be expected from the bare fact that it was called upon to produce nearly twice as much steel as in the previous year, or from the circumstance of market prices having risen fully $10 a ton on an average. Finished steel prices reached their lowest point as to some commodities late in 1921 and as to other commodities at the end of February, 1922. Some of the prices were below cost of production. Prices rose but moderately until they were forced up sharply by rising costs, partly due to the coal strike and its curious outcome and partly due to the general wage advance in the steel industry itself, effective Sept. 1, and which was indeed caused partly by the coal settlement. Mill operations had been restricted and many producers had to make, at higher cost, steel that had been sold at close to the minimum prices.

The steel industry leaves behind it, with the old year, practically all of its low-priced business, and with moderately full order books hopes to reduce its production costs somewhat in the new year by efficient and steady operation. The steel market is in good condition and speculation concerns itself chiefly with the question of how long the condition will last.

Engineers, "Engineers" And Ethics

IT HAS often occurred to us to wonder, particularly during the past 2 years when so many engineers were unemployed, what sort of a feeling must come over the graduate mechanical, civil or chemical engineer when his hopeful eye encounters, midway in the "male help wanted" column, the insert, "Engineer," and then- "for new apartment house; steam heat and lighting plant; must make own repairs." And the same thought springs to mind at the sight of the alluring prospect on the back cover of the magazine: "Be an automotive engineer. We teach you to repair any make of car by our 6-week correspondence course."

That picturesque hero of MONTAGUE GLASS' "Partners Again"—*Abe Potash*—voiced the thought when he remarked to *Mawrus*: "I suppose when we were in the cloak and suit business, I was a clothing engineer!"

With all due respect to the man who can wind an armature, or set a Corliss valve, or time an internal combustion engine, we begrudge him the title of engineer—not because he is one whit less essential in the economic scheme of things; not because we were fortunate enough to win a degree that he lacks and not because he is any less intelligent or skillful or clever than the M.E. or C.E., but simply because his craft is distinct from ours and therefore, in justice to each of us, should have a distinctive name.

The general public is directly responsible for this promiscuous application of the term "engineer." It is a practice which will be corrected—not by telling the public what the "engineer" is not, but by showing it what the engineer is. In other words, the engineer must and will come into closer contact with his fellow

men in his professional capacity. He must apply his trained mind to the problems of immediate interest to the community—political, economic and sociological as well as technical. He must inspire a wholesome respect for his ability to think straight, plan accurately and produce results efficiently. He must drive home a realization that his professional efforts are directed toward one goal—the common welfare. He must "sell" himself to the public.

That, as we see it, is the main significance of the recent action of a joint committee of the foremost American engineering societies, in formulating a code of ethics for engineers, reproduced on page 34 of this issue. The code is a good one, in that it is specific, complete and sets a high standard. But the engineer does not need a printed rule book to tell him what is right and in keeping with the ideals of his profession. If he is any kind of an engineer, he knows that good ethics is good business. Nevertheless, the formulation of such a code, embodying in black and white the ideas that had lurked in some odd corner of his mind as intangible sentiments, will serve to crystallize those ideals and awaken him to a lively appreciation of their importance. The mere existence of a standard code of ethics will probably change the practices and policies of very few engineers. But when every engineer becomes imbued with the ideals and dignity of his profession as embodied in this code, when his reputation for fidelity, fairness, loyalty, integrity and public spiritedness becomes second nature, then will the new conception of the engineer be generally accepted and then may we well rest in peace under the entirely adequate inscription—"Here lies John Doe—Engineer."

Slow Versus Rapid Carburizing Heats

IT IS NOT our intention to show that case-hardened parts have distinctive qualities which excellently fit them for certain exacting duties. Such would be trite. It is more timely to call attention to some of the means that have been adopted to cut the cost of the carburizing operation, or to substitute special alloy steels which retain considerable toughness after hardening.

It is our opinion, however, that if all the factors were properly appraised heat-treaters would not so readily substitute "rapid" carbonizers, highly energized with chemicals and unstable organic compounds, for the older charcoal and carbonate mixtures which have done yeoman service for so many decades. About the only argument advanced for energized compounds is the specious one that they reduce the time the work is to be held at high temperature, and consequently save a large amount of fuel. An operation which requires 24 hours or longer is thus shortened to 8 hours or less, and a night fireman may be discharged.

But not even all of that is profit. It takes far more fuel to heat a cold furnace and a cold charge every morning than it does to heat the same charge in a furnace already hot. Once the furnace and contents are at carburizing temperature, it requires surprisingly little fuel to maintain them so, balancing the radiation losses, if the furnace is properly designed or one of a bank. Furthermore, alternate cooling and heating break up the furnace brickwork with surprising rapidity, and introduce a high charge for maintenance.

Taking all these factors into consideration, if there is sufficient carburizing to be done to load a furnace daily, it will be found that it costs little if any more to keep a good furnace at heat constantly than for 8 hours daily. Then why not use it for the entire twenty-four? In other words, why discard the slow carbonizer for the rapid?

Such a slow cycle allows the work to come to heat more gradually and brings the work to temperature without high differences of temperature, edge to center, in the individual pots. On the other hand pieces packed near the corners of a pot in a rapid carbonizer and placed in a rapidly driven furnace reach carbonizing temperature a long time before the work buried deeper. Consequently the depth and kind of case in the work packed in the same box often show wide variations, depending upon placement. For the same reason, and due to the fact that rapid heats often produce hot spots in a furnace, the production from short carburizing cycles is frequently far from uniform, pot to pot. All this is due to causes other than the inherent instability and variability in action of complex organic carburizers, in turn producing wide variation in expected results.

Thus it seems that the illusive saving in fuel when using short heats is very likely to be far overbalanced by losses due to non-uniform work. There is no excuse for using a piece having a deeply carburized case except that it is of superior quality. If this fact alone were held in mind, practices would never be tolerated that militate against the production of work having the utmost uniformity in properties. In our estimation the case for slower carbonizers is clinched without considering the facts that they are cheaper in first cost and never change the alloy or steel pots used for containers.

Recording Failure As Well as Success

NEGATIVE results of research pay no dividends. This is an axiom that seems to be all to well recognized among industrial executives. But these same executives should not forget that negative results from a research will often save expenses of large magnitude.

Negative results from a research that was reasonably promising at the outset should be recorded as a guide for future action. It is for this reason that we feel more than usual satisfaction in the presentation of a series of articles on low-temperature carbonization by Dr. HARRY A. CURTIS, who has been directing the research and development work on the Carbocoal process for several years past. This process has come nearer to commercial success than any other low-temperature work thus far done in the United States. Thus it is entitled to special consideration. Furthermore, the record which is now spread for the information of all has been made most satisfying in completeness, because it includes a statement of failures as well as of successes, and it tells why failure was met.

Low-temperature carbonization is by no means a cure-all for our fuel troubles. But low-temperature carbonization does promise to be one of the important fuel developments of the next few decades. No one has yet succeeded in making low-temperature carbonization sufficiently cheap to be a thorough commercial success. But this does not mean that future efforts will not succeed. Each effort, though only partly successful, should bring us closer to ultimate complete success. And if in the future as in the present case investigators will give others the benefit of the experience in work that was not satisfactory, the energies in later study will be bent toward more promising lines and investigators will have the guideposts of past experience to direct their course most accurately.

Readers' Views and Comments

Copper and Brass Research

To the Editor of Chemical & Metallurgical Engineering

SIR:—Several recent utterances in the technical press have read almost like strictures on the activities of the Copper and Brass Research Association. Doubtless, therefore, you will not be averse to presenting the other side of the case. In the words of Mr. Agassiz, president of the association, "The underlying purpose of this whole effort is to develop to the maximum the domestic consumption of the metal"—surely a praiseworthy object, as you will agree. Continuing, the official statement issued at the recent meeting of the board of directors, says:

> Our plan is to provide through the instrumentality of the Copper and Brass Research Association a technical and advisory service which may be freely called upon by users of our metals—a service which no one copper or brass producer or manufacturer could reasonably be expected to undertake alone. Already, wide use is being made of these facilities. Information has been furnished on the use of copper and brass for almost every conceivable subject, from safety pins to locomotive boiler tubes.
>
> An important accomplishment has been the fact that many of the more than 2,000 manufacturers who produce articles made of brass or copper have taken advantage of the association's activity to individually advertise their products, thus extending the association's own educational work.

Lastly, you would be rash to cast reflections upon the undoubted eminence of the recently elected executive committee: R. L. Agassiz, president Calumet & Hecla Mining Co.; Walter Douglas, president Phelps Dodge Corporation; C. F. Kelley, president Anaconda Copper Mining Co.; Stephen Birch, president Kennecott Copper Corporation; Charles Hayden, vice-president Chino, Utah, Nevada Ray companies; F. S. Chase, president Chase Rolling Mills; Edward H. Binns, president C. G. Hassey & Co.; H. J. Rowland, sales manager Rome Brass & Copper Co. MARTIN SEYT.

The Problem of Marketing Ideas

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent interview with a talented chemical engineer he dropped an expression that had in it a touch of pathos: "I don't want cheese any more; I want to get out of the trap." Able, keen, nobody's fool in business either, he was finally cornered and hobbled in his work and in his living because the threefold nature of his task was too much for him. First, there was research and the development of his ideas through the laboratory stage. Second came the protection of his inventions by patent claims. In these fields he was thoroughly at home. Third, there was the sale of his patents or the granting of licenses under royalties and the exploitation of his inventions. Given a free hand with nothing else to do, he could manage this business also; not as a great negotiator, but acceptably, nevertheless. One difficulty lay in the fact that the ways of men are different from the ways of matter. Under precisely the same conditions and in the same physical state, matter will conform to its ways. You can trust matter if you know enough about it.

The study of man is a different field. What will a given man do under given conditions? Will he be straight or will he be crooked? Will he use good judgment, or will he let his thoughts go wool-gathering and proceed to guess wrong and invite failure? Here are problems in psychology that some men seem able to solve by prescience, although to outward appearances it would seem as if they were only guesswork.

Now the truly gifted man of research is full of ideas, contributions to humanity pressing for expression. If he addresses himself to negotiation with business men, the chances are that the ideas will die. He cannot invent and negotiate too. Men engaged in productive research are sacred possessions of their generation. They need aid and encouragement. They need friendly and sympathetic business relations. Negotiation with them is not a game like draw poker, although that is how the game is played in many instances. How shall the man of scientific talent and ability market his ideas without being beaten out of his rights? The answer to the problem will bring fame to the successful aspirant and peace and contentment to many inventors who know the ways of matter but not the ways of men.

New York City E. H.

Artificial-Silk Progress in Germany

A recent canvass of artificial-silk manufacturers in Germany revealed the fact that few if any of these mills are today in a position to consider orders from abroad because of the large domestic demand. Many mills already have orders on hand sufficient to keep them busy for several months, and others have advised that they will not be in a position even to consider foreign business for some time, says *Commerce Reports* for Dec. 25, 1922.

One of Germany's best-known former ammunition manufacturers has evolved from guncotton a new product known as vistra, which was lately exhibited at the Munich Trade Exposition. It is understood that vistra may be mixed with silk, flax, cotton or wool, and a number of samples of imitation Smyrna rugs, silk sweaters and Gobelin tapestries employing it were shown at Munich.

Research on Edible Gelatine

The Edible Gelatin Manufacturers of America, Inc., announces the establishment of an industrial fellowship in the Mellon Institute of Industrial Research for the purpose of ascertaining the real food value of edible gelatine in its manifold applications in the American dietary.

In addition to experimental investigations, a correlation of all available facts regarding edible gelatine will be made, to be held at the disposal of all users and prospective users of the product. It is hoped that real service may be rendered by supplying scientific data and technical advice. The present incumbent of the industrial fellowship is Thomas B. Downey, who will be glad to furnish any available information to those interested in the uses of edible gelatine.

A Glimpse of the Liquid Carbon Dioxide Industry

BY ALAN G. WIKOFF

Efficient Utilization of Energy and Materials in Coke Process for Production of Carbon Dioxide—Associated Manufacturing Departments, Which Make It Possible to Render Complete Service to the Industry

LIKE sulphur dioxide, carbon dioxide is one of the great inorganic intermediates, although this fact is not generally realized, since the bulk of the production reaches the market in a combined form. Thus the amount of carbon dioxide required for the manufacture of sodium carbonate and bicarbonate by the ammonia-soda process is probably not far from 500,000 tons per year. Gases from limekilns in which the coke fuel is mixed directly with the limestone form the source of supply. Limekiln gases are also used for the carbonation of sugar solutions during the refining process. In each of these industries the carbon dioxide is used on the spot and the lime produced simultaneously is also required in the process

With the growth of the carbonated beverage industry it became necessary to perfect arrangements whereby carbon dioxide could be conveniently transported and distributed. The gas was liquefied by compressing into strong steel cylinders, and it is the development of this phase which is usually referred to as the carbon dioxide industry. Nearly 60,000,000 lb. of liquid CO_2, valued at more than $6,500,000, was produced in 1919.

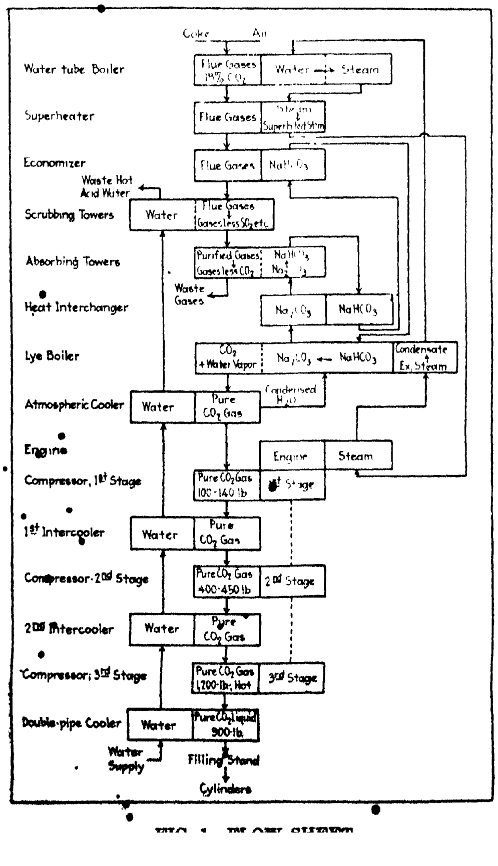

FIG. 1—FLOW SHEET

FIG. 2—FILLING CYLINDERS WITH CARBON DIOXIDE

Obviously, for beverage purposes purity is a primary consideration and it is also essential to exclude other gases. These points must be considered in selecting the method of production. Since power is required to compress the gas, the recovery of pure CO_2 from the flue gases of a coke-fired boiler has proved to be most economical. Recently some liquid CO_2 has been produced as a byproduct of industrial alcohol fermentation, but the greater part is made by the coke process. This is used by the Liquid Carbonic Co. in its thirteen plants, which have a total annual capacity of more than 30,000,000 lb. These are located at Chicago, Pittsburgh, St. Louis, Memphis, New York, Cincinnati, Kansas City, Minneapolis, Atlanta, Dallas, Boston, Philadelphia and Ashland. While of course the different installations vary somewhat in detail, the Chicago plant of this company may be taken as typical. The associated plants here are also of particular interest in showing the logical development of an organization for rendering complete service to an industry. Starting with the gas and carbonators, the company is now prepared to furnish every detail of the dispensers' and bottlers' requirements.

Briefly, the process of manufacture consists in burning coke under a boiler, absorbing the carbon dioxide in sodium carbonate solution and boiling the sodium bicarbonate solution to liberate pure CO_2, which is then compressed into cylinders. Steam furnished by the boiler supplies the energy required for compression and the heat in flue gases and exhaust steam is used to best advantage. As a result, the process forms an interesting example of efficient utilization of energy and materials. The various cycles and counter-current arrangements are indicated in the accompanying flow sheet, Fig. 1, and described in some detail in the following paragraphs.

Low sulphur content is a primary requirement for the

FIG. 3—MARBLE YARD

coke used. It should be low also in ash and the fusion point of the ash should be as high as possible. At present, coke containing less than 0.8 per cent sulphur is burned at Chicago. It may originate in either beehive or byproduct ovens.

This coke is burned under 200-hp. Kroeschell combination fire and water-tube boilers equipped with superheaters and economizers. Hand firing is employed, combustion being controlled through Ellison differential draft gages (connected right over the fire and also after the boiler) and a Uehling CO_2 recorder with an indicator on the boiler front. The flue gases regularly contain 18 to 19 per cent CO_2. Coke consumption is about 850 lb. per hour per boiler—approximately 1 lb. coke being required to produce 1 lb. of pure carbon dioxide. The boilers operate independently, as the plant consists of two complete units to obviate the possibility of a shut-down in case of accident to some part of a unit. As the two installations are exact duplicates, only one need be described.

After some of the heat has served to superheat the steam and to warm up bicarbonate solution in the economizer, impurities in the flue gases, particularly smoke, dust and sulphur dioxide, are removed by countercurrent scrubbing with water in two limestone-filled towers run in series. Because of the final temperature of the scrubbing water practically no carbon dioxide is lost. To insure complete removal of sulphur compounds it is essential that all the sulphur in the coke should have been burned to SO_2, with possibly traces of SO_3. Hydrogen sulphide is always avoided because of the tendency to pass right through the purification process and contaminate the product. The hot acid water discharged from the scrubbers is thrown away, as it is not possible to use it economically.

Absorption of carbon dioxide takes place in two coke-filled towers operated in series. Each tower is about 100 ft. high and contains about 110 tons of coke. A Roots blower draws the gases through the boiler and scrubbers and forces them through the two absorbers counter-current to the alkaline liquor, which enters the top of the first tower as sodium carbonate solution and leaves the bottom of the second absorber as sodium bicarbonate solution. Circulation is maintained by Goulds centrifugal pumps. Complete removal of the carbon dioxide is not feasible and the waste gases still contain about 10 per cent CO_2. This represents the economical limit, although in some cases the addition of a third tower may increase the recovery more than enough to offset the extra investment charges.

From the bicarbonate solution, carbon dioxide is recovered by simply boiling. The solution is preheated by passing through a heat interchanger, then through the economizer previously noted in connection with the coke-fired boiler. It then passes to the lye boiler, which is heated by exhaust steam. Here the carbon dioxide is boiled off under 8 to 9 lb. pressure, while the regenerated carbonate solution returns to the absorbers, passing first through the heat interchanger, where it serves to preheat the bicarbonate liquor about to enter the lye boiler.

Great care is taken to see that pipes leading from the absorbers to the boilers are at all times completely filled with liquor so that no air may enter the system. Furthermore, a pressure of 4 to 5 lb. is maintained on the CO_2 until it reaches the compressors so that it will not be possible for air to enter even should there be slight leaks in the piping. As the CO_2 is liberated from a boiling aqueous solution it is, of course, saturated with water vapor, but this is condensed in an atmospheric cooler, leaving the pure CO_2 ready for compression. The condensate is returned to the alkaline liquor cycle.

Still under slight pressure, the gas passes to a three-stage Worthington compressor driven by a 125-hp. Erie City Iron Works Lentz engine. The first stage is double acting and raises the pressure to 100-140 lb. After passing through an intercooler, this is increased to 400-450 lb. in the second stage, followed by another intercooler and the third stage, which delivers the gas under 1,100-1,200 lb. A double pipe cooler reduces the temperature below the critical temperature (31.35 deg. C.) and the carbon dioxide liquefies. It is distributed in the familiar 20-lb. or 50-lb. steel cylinders. These are placed on scales at the filling stand, the tare adjusted and the proper amount of liquid CO_2 run in. The cylinders are then inverted so that the valves dip in a trough of water, which indicates any leakage. The cap is put on and another test made with the stem open

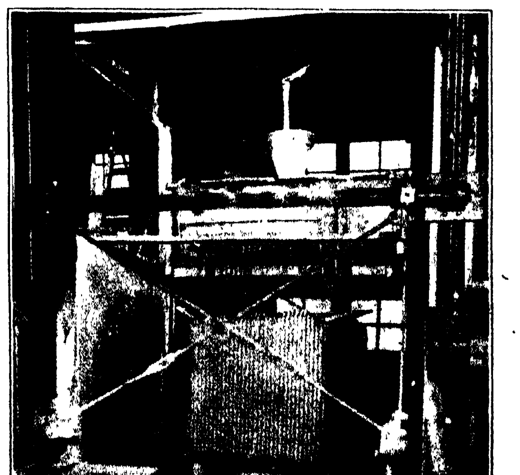

FIG. 4—GANG SAW CUTTING MARBLE SLABS

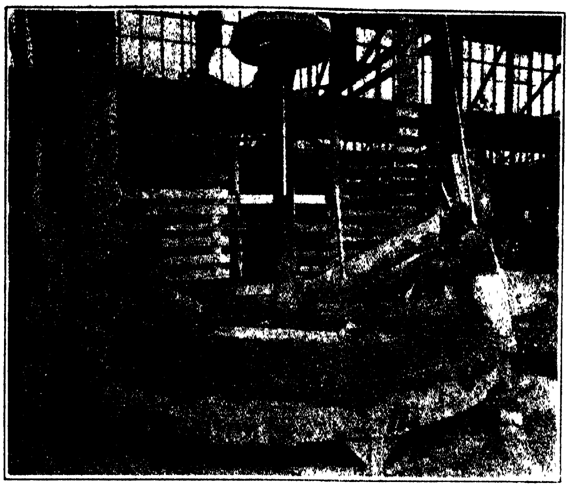

FIG. 5—RUBBING BED

to make sure that the cap is tight. The pressure in the cylinders is about 900 lb. at 70 deg. F. The operations of filling the cylinders and testing the valves for leakage are shown in Fig. 2.

At this point let us return for a moment to a consideration of the interrelation of the different steps in the process as indicated by the flow sheet. Coke and the air required for its combustion enter the system at the boiler and the products of combustion are separated into waste gases and pure carbon dioxide. Water from a deep well flows through the pure CO_2 coolers in a counter-current direction and is then fed to the scrubbing towers, emerging as waste hot acid water. Two closed cycles complete the process. The alkaline liquors circulate continuously through absorbing towers, heat interchangers, economizer and lye boiler. Superheated steam from the water-tube boiler operates the engine, the exhaust serves to boil the bicarbonate solution, while the condensate is returned to the boiler. Actual operation of the plant requires the services of only three men --engineer, fireman and a man at the filling stand. Men engaged in testing and handling cylinders raise the number of employees to five or six. An experienced chemical engineer is in charge of the plants.

Cylinders are purchased and as they have been tested under the supervision of the Bureau of Explosives by

FIG. 6—POLISHING MACHINES

the manufacturer before sale it is not necessary to test them for 5 years. As the empty cylinders are received for refilling, the dates stamped on them are examined and those which require testing are set aside. Others about which there is the slightest doubt are added to the group. In testing, a cylinder is filled with water and the pressure raised to 3,000 lb. per sq.in. by means of a hand-operated hydraulic pump. The cylinder is permitted to remain under pressure for 2 minutes, during which time any expansion is indicated by a drop in pressure. Should the pressure drop exceed a small permissible value, the cylinder is rejected. A Columbia recording gage gives a permanent record of all tests.

As an additional safeguard the valve is provided with a safety vent closed with a metal disk which will rupture should the pressure exceed 2,700 lb. In this way the bursting hazard becomes negligible, since the normal pressure in the cylinder is only about 900 lb. The valves are of the packing type and are made by the company.

Owing to the universal demand for carbonated beverages, it has been necessary to develop a distribution system which embraces practically every community, by means of distributing depots and jobbers, where

FIG. 7—GENERAL VIEW OF TIN SHOP

large stocks of full cylinders are kept. This ready availability is an important factor with the chemist or the engineer who is considering the use of carbon dioxide for its inertness or its chemical properties. It is the cheapest inert gas available.

While the greater part of the output is used for carbonation purposes, several other applications have been developed. For refrigeration, particularly household units, it possesses certain advantages over ammonia and sulphur dioxide. The manufacture of salicylic acid is typical of its use in the production of chemical products. Other applications include: Fire protection, food preservation, water purification, local anæthesia. New uses are constantly being developed through a fellowship which has been established for the purpose by the carbon dioxide manufacturers at the Mellon Institute for Industrial Research.

While the carbonated beverage industry could not exist without a convenient gas supply, it is equally true that without additional equipment a cylinder of carbon dioxide would be of no value to the dispenser. Means must be provided for preparing charged water and delivering it to the fountain. It is only natural that the

manufacture of machines for this purpose should supplement the production of carbon dioxide. Following this idea to its logical conclusion, it is not surprising to find that the greater part of the Chicago plant of the Liquid Carbonic Co. is devoted to the manufacture of products other than CO_2. A brief outline may serve to indicate the diversified character of these operations.

Having supplied the dispenser with gas and carbonator, it is but a step to the complete fountain with all accessories. Production of the fountains requires a marble shop, wood-working or cabinet shop, and sheet-metal department, together with facilities for assembling the various parts.

Marble from foreign and domestic quarries is received in the form of the huge blocks shown in Fig. 3. These are cut into slabs by gang saws, Fig. 4, the blades of which have no teeth. Cutting action is due to sharp sand carried by streams of water from an overhead trough. Continuous operation for about 2 weeks is required to cut through an 8-ft. block. After cutting to size, the slabs are polished. This operation starts on the large horizontally rotated cast-iron wheels or rubbing beds shown in Fig. 5, where fine sand forms the abrasive. High polish is obtained by the use of carborundum and other finer materials on machines of the type illustrated in Fig. 6. After finishing to size, the pieces are fitted together to make sure that there will be no difficulty in erecting. Meanwhile the rest of the fountain—the wooden or steel framework, the cork insulation, the pressed sheet-metal parts, the fixtures and fittings—has been assembled in the tin shop, Fig. 7. Certain sizes and arrangements have been adopted as standard, although much special work must be done to meet the whims of certain customers.

FIG. 8—FOUNDRY

Mention has already been made of the carbonators used by dispensers. A larger model is required by establishments which make bottled carbonated beverages. This is an important and growing branch of the industry, and a complete line of equipment has been developed to meet the needs of the bottler. In addition to the carbonator, there are the siruper, the filler, the crowner and the washer. The operation of the carbonator, siruper and filler has been discussed in an article on the ginger ale plant of the Beech-Nut Packing Co.[1]

FIG. 9—SPINNING BLOCK TIN CARBONATOR LINING

A good-sized plant is required to turn out this equipment, together with such miscellaneous parts as cylinder valves and pressure regulators. There is a large foundry designed for crucible melting of non-ferrous metals and alloys, Fig. 8. The non-ferrous castings, and also the variety of iron and steel parts, are worked up in a well-equipped machine shop connected with the plant, and finally assembled.

Solutions of carbon dioxide being weakly acid, it is necessary to exercise caution in choosing the materials with which they may come in contact, which explains the extensive use of non-ferrous metals. Only tin and silver are used in contact with carbonated water and sirups containing fruit acid. The carbonators are lined with block tin and one of the interesting operations in the machine shop is the spinning of this lining, Fig. 9. Many of the fixtures on the fountains—for example, the sirup pumps—are silver plated, so that the plant includes a silver-plating department which is one of the largest in the Chicago district for industrial purposes.

Fig. 10 shows the final assembly of the carbonators. These machines are very compact and are entirely automatic in operation. Carbon dioxide from a cylinder connected through a reducing valve is passed into water agitated in the mixing chamber, water pump and agitator being driven by an electric motor. Automatic

FIG. 10—ASSEMBLING CARBONATORS

[1]"Automatic Equipment and Chemical Control," G. L. Montgomery, *Chem. & Met.*, vol. 27, p. 160, July 26, 1922.

control of motor and gas supply is obtained through the counterbalanced external chamber which operates a rocking mercury switch. Although in direct communication with the mixing chamber, so that free flow of liquid is possible, the external chamber can move up and down within certain limits and the counterweight is so adjusted that fluctuations in the liquid level will operate the switch.

Another large department prepares crushed and preserved fruits, soda fountain flavors and bottlers' extracts. Fresh fruits, such as strawberries, cherries, peaches and pineapple, are cooked in closed glass-lined kettles, canned and placed in storage for shipment. Soda fountain flavors as a rule contain the necessary amount of sugar sirup, while bottlers prefer to add their own sirup and save transportation charges. Recent progress in this direction has led to the development of highly concentrated emulsions, which contain practically nothing but the flavoring materials.

This department has a large laboratory for control work, research and service to customers, under the direction of an experienced chemist. Such tests as the gas plants may require are also conducted here.

A small fountain is installed so that all flavors may be tested by tasting. There is also complete equipment for conducting a bottling test, as well as several ice cream machines for work on this product. Refrigeration is supplied by a Kroeschell CO_2 machine.

While it has not been possible to go into detail, it is hoped that this review may serve to show how a large manufacturing industry has been built up around the production and distribution of a single chemical product.

The writer is greatly indebted to the management for courtesies extended and in particular to Edwin D. Hale, Chemical Engineer, for assistance in the collection of data.

Value of Commercial Training in Technical Schools

That engineering college graduates are handicapped without a supplementary commercial training is the basis of research investigations just completed by Dr. W. F. Rittman and W. F. Reilly, of Carnegie Institute of Technology, Pittsburgh.

A study of the present occupations of Carnegie Tech graduates was made. Of the graduates from 1908 to 1921, the investigations showed that approximately 67 per cent of the total engineering graduates are now engaged in commercial or managerial work. This majority becomes significant in consideration of the fact that "engineering" graduates include a wide range of highly technical fields such as mechanical, electrical, civil, chemical, metallurgical, mining, sanitary, and science.

An interesting tabulation in the report shows the following percentages of engineering graduates in all departments who are now in commercial or managerial capacities: mechanical engineering, 65 per cent; electrical engineering, 60 per cent; civil engineering, 73 per cent; chemical engineering, 59 per cent; commercial engineering, 91 per cent; metallurgical and mining engineering, 67 per cent; sanitary engineering, 60 per cent; science, 77 per cent.

One of the two most important generalizations cited by the authors in their report is that "the great majority of graduates use their technical education as a means of getting into commercial or managerial work. It is believed that a similar study of the activities of the graduates of other technical institutions would show this same order of classification."

Glass Rings—A New Filling Material for Towers*

By F. C. Zeisberg
Chemical Engineer, the du Pont Company

In a recent article[1] entitled "The Efficiency and Capacity of Fractionating Columns," W. A. Peters, Jr., describes experiments on fractionating columns packed with various materials; among others, hollow cylinders. It was shown that hollow cylinders have so much greater capacity per square foot of gross cross-sectional area than solid filling material of approximately the same dimensions that it seemed worth while pursuing the matter to see whether such hollow cylinders in small sizes could not be produced commercially. The desirability of the smaller sizes lies in the fact that the separating efficiency in a packed fractionating column increases almost directly as the size decreases.

So-called Raschig rings of earthenware and metal have been used for some time, but of larger dimensions than Mr. Peters' experiments indicated to be desirable. Thus, the General Ceramics Co. makes unglazed earthenware rings, 1x1 in. with $\frac{1}{8}$-in. walls, of two different types. One of these is a plain, open-ended, hollow cylinder, the other a similar cylinder with four notches at each end. Maurice A. Knight makes both glazed and unglazed cylinders in four sizes: $\frac{3}{8}$ in. with $\frac{1}{8}$-in. walls, [illegible] in. with $\frac{3}{16}$-in. walls, 1 in. with $\frac{3}{16}$-in. walls and $1\frac{1}{4}$ in. with $\frac{1}{4}$-in. walls.

In Germany both porcelain and metal rings have been in use for some time, but so far as we have been able to learn the smallest size used up until now is 15x15 mm., with 2-mm. walls in the case of porcelain and 0.5-mm. walls in the case of metal.

In England, Lessing[2] has attempted to improve the metal ring by adding a single central partition. This increases the surface of a given ring about 32 per cent. The Hydronyl Syndicate of London is marketing Lessing's ring in several sizes and in a variety of metals, such as copper, iron, aluminum and nickel. The cost of these rings is rather high.

It is probably true that the commercial limit has been reached with respect to further decrease in size of earthenware rings. Not only does the effective free space rapidly decrease as the ring size decreases, owing to the necessity of keeping the walls comparatively thick, but the cost of handling the rings in the drying and burning operations rapidly increases also. Furthermore, for some purposes, as, for example, handling hot sulphuric or nitric acids, the earthenware rings are not entirely suitable, tending to disintegrate.

While metal rings can easily be made of any desired size, no matter how small, by the use of automatic machinery, here the increase in surface per cubic foot of rings as the size decreases can in some instances work harmfully rather than otherwise. For example, in the distillation of acetic acid through a copper column filled with copper rings, the action of the acid on the copper is comparatively slight, measured in inches penetration per month, but when the enormous area exposed by the smaller size rings (252 sq.ft. per cu.ft. for $\frac{1}{4}$-in. Lessing rings) is taken into consideration, the total amount of copper dissolved is no insignificant factor.

TABLE I—PROPERTIES OF GLASS FILLING RINGS

Chemical Department, E. I. du Pont de Nemours & Co.

Size*	4	5	6	7	8	9	10	11	1
No. per cu.ft.	369,000	189,000	109,300	68,800	46,100	32,400	23,600	17,750	13.
Wt. per cu.ft., lb.	52.0	49.1	46.2	43.4	40.5	37.7	34.8	32.0	29.
Sq.ft. per cu.ft.	415	332	274	233	203	178	160	144	
Per cent free space	66	68	69	71	73	75	77	79	
Wall thickness, mm.	0.58	0.63	0.68	0.73	0.78	0.83	0.87	0.92	0
Resistance, inches H₂O	9.4	6.7	5.0	3.8	3.0	2.4	1.9	1.55	1
Price per cu.ft.	$115.00	$65.00	$42.00	$31.00	$24.00	$20.00	$17.00	$15.00	$13

* The size number of the rings is simply the outside diameter in millimeters

This holds, of course, wherever the metal composing the ring is attacked, however slightly, by the vapors or liquids coming in contact with it, and this condition obtains in a surprisingly large number of works-scale cases.

It seemed to us, therefore, that neither metal nor earthenware promised to be the ideal material of which to fabricate small rings. In looking about for such a material, glass naturally suggested itself. Glass is a fairly cheap material, is inert to a large variety of chemicals, possesses the necessary strength, is a poor conductor of heat (which is an important consideration in a column where reactions occur having a marked temperature gradient) and is readily cleaned.

Considerable effort has been spent on methods of manufacturing these glass rings, and this has been successful to the point that the chemical department of the du Pont company is now in a position to market small glass rings at prices which make them attractive for a number of operations, notably for the filling of small distilling columns. The rings can be made in a large range of sizes. For each operation, however, there is an optimum size, indications being that for all-around purposes ring No. 11 is about the best. Table I shows the properties of the various size rings.

It should be emphasized that the weight, wall thickness, free space and surface shown in the table are only approximate. The wall thickness for a given size can be varied considerably, and with it all the other properties vary as a matter of course. The properties given, however, are for what appears the best proportioned ring.

The resistance shown is the pressure necessary to force 1,000 lb. air per hour, at 20 deg. C. and 760 mm., through a bed of rings having a cross-sectional area of 1 sq.ft. and a depth of 1 ft. The figures were calculated by the formula given in F. C. Blake's paper, "Resistance of Packing to Fluid Flow," and are probably accurate to within less than 10 per cent.

The prices given are tentative. They are for quantities of 50 cu.ft. or more and are f.o.b. Wilmington, Del. Prices on small quantities of the smaller rings for laboratory use will of course be considerably higher.

The du Pont company has these rings in use in several distilling operations. For example a 9-in. column, filled with 13 ft. of No. 9 rings, is producing 2,000 lb. per day of 90 per cent (by weight) alcohol from a 60 per cent feed alcohol, with a heat flow up the column of 220,000 B.t.u. per sq.ft. of cross-sectional area per hour. The performance is equivalent to that of a thirty-five-plate column, and has been satisfactory from the first.

In a second operation a 4-in. column, packed with 11 ft. of No. 11 rings, is used in stripping a 28 per cent ammonia liquor. The feed rate is 90 lb. of liquor per hour, with a heat flow of 395,000 B.t.u. per sq.ft. of cross-sectional area per hour. A vapor at approximately room temperature is delivered from the top of the colum while the hot water running from the base is NH_3-fre In this case only 6 ft. of the packed space is real functioning, equivalent to about sixteen plates, the r maining 5 ft. being used as insurance.

To illustrate the readiness with which these gla rings can be cleaned, this NH_3 column stopped up se eral weeks after being put in operation, and when was opened the rings were found stuck together with dark brown deposit which was found to be iron sal The rings were simply removed, treated with comme cial hydrochloric acid, which readily dissolved th deposit, washed with water and replaced in the column.

In conclusion, it should be stated that the du Por company has made what is felt to be only a very limite application of these rings to works-scale operation: Those applications susceptible to patent protectior however, as well as the phases of ring manufactur which can be covered, have been taken care of.

Sagger Problems Being Investigated

Saggers are containers employed in manufactories o chinaware for holding plates, cups, saucers, etc., dur ing the firing in the kiln. These containers are mad of clay which must have considerable strength and b of good refractory quality. The Bureau of Standard is conducting a thorough investigation involving a geo graphical study of sagger clays to classify them ac cording to their properties, and finally to see what ma be done toward increasing the life of the sagger.

To obtain a list of the sagger clays used throughout the country, letters were sent to 100 different manufacturers using these clays. About ninety different clays or rather clays sold under approximately ninety different names, are used for saggers in the United States.

Samples of fifty-two different clays, representing as well as could be judged all the important types, are being obtained in 200 lb. lots from the users rather than from producers or dealers. Manufacturers are contributing these rather large samples from their stocks and prepaying the freight to Washington.

In order to classify the sagger clays according to their properties, they are being subjected to the following tests: Water of plasticity, shrinkage, porosity, transverse strength, and burning behavior at five different cones. It is considered necessary, in order that the results of these tests may be of value, to devise, where necessary, methods or modifications of methods which will insure greater accuracy than is usually attained in such measurements. This involves the elimination of sources of variation all along the line in order to obtain close checks in the final results. As this is a feature which justifies closer attention than it has received up to this time from ceramic industries, it is proposed to include in the report of this investigation not only averages but maximum departures from these mean values.

The Low-Temperature Carbonization of Coal

I—The Development of the Carbocoal Process at the Irvington Plant of the International Coal Products Corporation

BY HARRY A. CURTIS AND WALTER J. CHAPMAN

THE present paper is the first in a series of articles which will be published by the senior author and several of his co-workers dealing with the project of manufacturing a smokeless fuel through processes involving the low-temperature distillation of coal. In describing the development of the Carbocoal process in the present paper there will necessarily be included considerable data of general application in any low-temperature carbonization process, for many of the problems encountered in the development of this particular process are not specific to the process, but are inherent in the nature of the operations to be carried out, regardless of the methods used.

There have been about sixty different retorts invented for carbonizing coal at relatively low temperatures. Many of these retorts are worthless because they disregard some of the fundamental principles of the art. It has cost time and money to discover these principles, and it is well that they are recorded. Nor is the problem of producing smokeless fuel solved when a successful retort has been developed. The question of what to do with the carbon residue turned out by such a retort must be answered also, for this carbon residue is not in suitable shape for the market.

Looking back over the records of the large-scale experimental work carried on at the Irvington, N. J., plant, it is easy to see that the company rushed into the use of large-scale apparatus and consequent heavy expenditures before small-scale experiments had disclosed the essentials of the Carbocoal process. It is true that inevitably there would have come a time in the development of the process when only large-scale apparatus would give the final data for plant construction, but the large-scale work at Irvington was premature. All of the early work at Irvington suffered from lack of good engineering, and many of the experiments were performed unnecessarily. In spite of these facts, however, progress was slowly made toward a successful process and a great deal of experience in the art was accumulated.

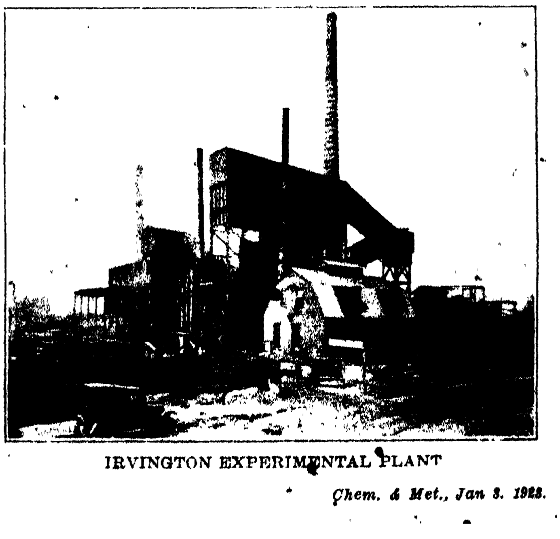
Experimental work was begun at the Irvington plant in May, 1915, and discontinued in June, 1921, after the Clinchfield, Va., plant had been in operation for a year. During this period several types of full-size low-temperature retorts were built and tested; methods of handling the carbon residue were devised; the art of briquetting the carbon residue was developed; and methods of carbonizing the briquets to make them smokeless were worked out. In the following pages a very brief summary of this work is presented.

RETORTS NO. 1 AND NO. 2

The original scheme of the Carbocoal process was to remove only such a part of the volatile of the coal as would leave the residue plastic and then to briquet the plastic.[1] This idea was later abandoned, for reasons which will appear, but Retorts No. 1 and No. 2 were built with this original scheme in view.

Retort No. 1 was fabricated by H. W. Caldwell & Sons and set up at Irvington during the summer of 1915. It consisted essentially of a horizontal, stationary, cast-iron cylinder, 36 in. in diameter and 17 ft. long, made in two sections, with a single paddle shaft through the center. The paddle shaft was an 8-in. wrought-iron pipe, with gudgeons for bearings in each end, and carried about forty paddles bolted in the shaft, the paddles being set at an angle so as both to stir the coal and to advance it through the retort. Crushed coal was fed from a bunker through a 6-in. helicoid screw, and dropped down a 7-in. pipe into the retort. The plastic carbon residue was discharged through a single 6-in. helicoid screw turning in a 7-in. pipe casing. The paddle shaft, feed and discharge were driven from a single motor through a worm gear. A simplified sketch of this retort is shown in Fig. 1.

When Retort No. 1 is regarded in the light of 7 years' accumulative experience which the company has now had in this line, it is amusing that such a retort should have been built and that most persistent efforts should have been made to operate it. And yet patents are being granted right along on retorts as impossible as this one. Tests were started with Retort No. 1 in September, 1915, and continued for more than a year in spite of the fact that practically every test ended in disaster within a few hours after it was begun. The final stage in every test which was not earlier terminated by plugged feed, plugged discharge or broken machinery was a retort plugged with carbon residue. The plastic mass of distilling coal would wind around the paddle shaft and paddles and gradually bake in place until it was impossible to get any more coal into the retort. Such is the inevitable result when a fusing coal is put into such a retort, and we may state as one of the fundamental facts of the art of low-temperature carbonization that any device for stirring a fusing coal during carbonization will inevitably become more and more heavily gummed up with carbon residue unless some positive mechanism be provided for removing this deposit. Likewise all simple revolving cylinder retorts will fail with fusing coal, and no amount



IRVINGTON EXPERIMENTAL PLANT

[1]See C. H. Smith patent, U. S., 1,224,424.

of argument on the part of their inventors will prevent the distilling coal from sticking on the sides of such a retort until it is plugged. Furthermore, all retorts involving the use of internal screws to agitate and convey the distilling coal will fail to handle a caking coal unless some means of keeping the screws clean be provided.

It must be recognized that caking coals, which fuse in the retort and pass through every stage from a fairly fluid mass to a brittle solid, act entirely differently from lignite or oil shale. Again and again retorts which have been used on lignite or shale are brought forward as suitable equipment for carbonizing all sorts of bituminous coals, and not one-half of 1 per cent of such retorts will operate at all on caking coals. Such was the lesson which Retort No. 1 taught, or tried to teach, almost daily for over a year at the Irvington plant. And it finally got the idea across, but not until dozens of tests had ended with a plugged retort and Retort No. 2 had been built along similar lines and had likewise failed.

Several other difficulties were made apparent during the course of the tests on Retort No. 1. The feed screw would frequently jam, due to a plug at the foot of the vertical section of the 7-in. feed pipe, this causing the pipe to fill up and very soon bind the screw with coal. When Retort No. 2 was built, early in 1916, the crushed coal was fed to the retort by a short plunger device at the floor level of the retort. This also gave much trouble. The problem of coal feed was eventually solved by using a 9-in. screw set horizontally and emptying directly into the retort through the end-plate, above the paddle shafts, as will be shown later in sketches of the Clinchfield type of retort. In this arrangement the retort paddles sweep past the discharge end of the feed screw and keep it free.

The single screw for discharging the carbon residue from Retort No. 1 was a failure. It would plug full of plastic carbon residue and cease discharging or break its driving mechanism. The single discharge screw was finally removed and two 6-in. screws were set in a brick discharge box at right angles to the axis of the retort. These also plugged. Nine-inch twin screws were then tried, and these worked a little better, but still the discharge would plug up frequently with plastic material. The 9-in. twin screws were next transferred to Retort No. 2, and Retort No. 1 rebuilt with a 24x36-in. cross bolted to the discharge end, with a 24-in. chute for discharging the carbon residue, the chute being closed with hand-operated slides. The slides became gummed up with heavy tar and could not be worked. A slide valve was then substituted for the hand-operated slides, but this also stuck and had to be abandoned. The problem of an entirely satisfactory discharge mechanism was never wholly solved at Irvington, although numerous schemes were tried out on the various retorts built and tested. The scheme finally adopted, known as the "Vesuvius discharge," is shown in the sketch of the Clinchfield retort, and subsequent experience with it has shown that it is a failure.

It must be borne in mind that during all of this first year of experimenting the idea was to operate the retort so as to yield plastic carbon residue and to briquet this residue without binder. It was not often that enough of the carbon residue could be made for use in briquetting tests. It was found impossible to control the operating conditions closely enough to get a continuous discharge of plastic material. An attempt to briquet the plastic material with a brick press failed, and the attempts to briquet it in roll presses were not very successful. Finally, in the summer of 1916, it was decided to abandon the plastic residue idea and to carry the carbonization to a non-plastic residue, later briquetting this residue with a suitable binder. Retort No. 1 was then provided with a hand-operated ram for breaking the carbon residue from between the paddles. This ram was a heavy I-beam which was run lengthwise through the retort at intervals, the paddles being stopped and the I-beam pushed between the rows of paddles. By frequent use of this ram and by carrying the carbonization past the plastic carbon residue stage, Retort No. 1 could occasionally be kept going for several hours before a breakdown, and in this way enough carbon residue was obtained for experimenting in briquetting, etc.

A Vertical Primary Retort

While Retort No. 1 was being tested, a vertical primary retort was set up and attempts made to operate it. Fig. 2 shows the essential features of this retort. Of the few utterly absurd pieces of apparatus built by the company, this vertical retort would easily take first rank. It is difficult to discover a single commendable feature in the whole apparatus, yet cur-

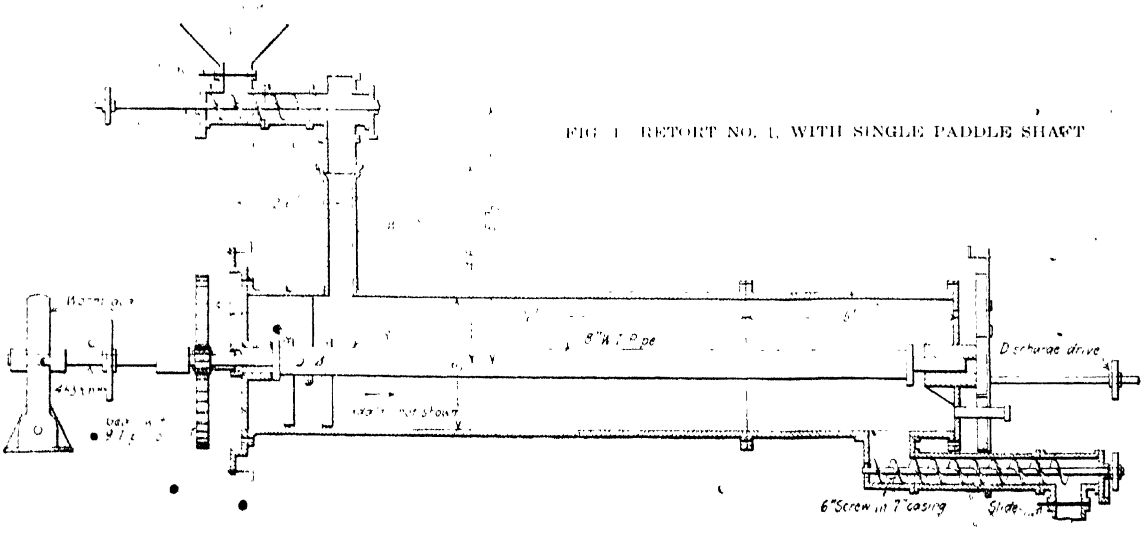


FIG. 1 RETORT NO. 1, WITH SINGLE PADDLE SHAFT

rent patent literature is replete with descriptions of no better retorts, and within the past few years one of the present authors has been asked to report on three low-temperature retorts involving most of the mistakes of this design. Any one familiar with the behavior of a fusing coal when distilled will note from a casual inspection of Fig. 2 that:

a. The feed pipe on this retort would plug as soon as the pipe got hot enough to begin even a very slow distillation of coal at its lower end.

b. That plastic coal mass would wrap around the paddle shaft and paddles and fill the retort so that no more coal could enter.

c. That the paddle shaft, paddles and driving mechanism are too high and would fail.

d. That plastic carbon residue would never get by the slide shown at the foot of the retort.

e. That even if plastic carbon residue got by this slide, it would soon wrap around the discharge screw and plug it.

f. That even if plastic carbon residue would pass the slide and the screw, it would stick in the elbow at the outer end of the screw.

g. That the gas offtake would have to be cleaned every few minutes.

h. That the slide at the bottom of the retort could not be moved after an hour or so of operation.

i. That the life of the metal retort would be short and that no provision is made for replacing it readily.

Retort No. 3

Retort No. 3, which is sketched in Fig. 3, was the first retort built with twin paddle shafts and self-cleaning paddles. This scheme of preventing carbon residue from plugging the retort was entirely successful and was used in all subsequent designs. The feed screw on this retort was located at the floor level of the retort, and gave trouble occasionally; it was eventually moved up so as to discharge above the level of the paddle shafts.

Retort No. 3 was also the first retort to be built with a carborundum lining, such as used later in the Clinchfield retorts. Carborundum possesses the advantages of strength and relatively high heat conductivity. It slowly deteriorates in an oxidizing atmosphere at 1,600 deg. F. (flue temperature), however, and although it was adopted for the commercial Carbocoal plant at Clinchfield, Va., it is probable that better material will be found eventually.

Retort No. 3 had heating flues running lengthwise the retort, with burners at the feed end. In operation it was found best not to use the burners across the top of the retort, and in subsequent designs no provision was made for heating the retort top.

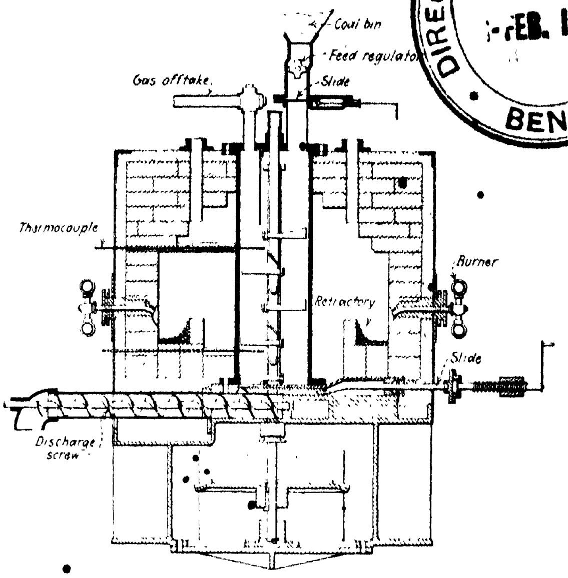

FIG 2—VERTICAL RETORT, WITH SINGLE PADDLE SHAFT

The discharge chute dropped the carbon residue onto a pair of revolving breaker arms, which broke up the larger pieces, and then into a star-wheel which served to seal the retort partly. This discharge gave considerable trouble due to gumming of the star-wheel with heavy tar and plastic carbon residue.

The hydraulic main and gas offtakes on Retort No. 3 gave continuous trouble through plugging with pitch and coke deposit. This equipment was eventually abandoned in favor of the scrubber standpipe installed on the Clinchfield retort. It was proved at Clinchfield a few years later, however, that the successful operation of such a hydraulic main is a matter of using liquor sprays correctly.

In spite of the minor difficulties mentioned above, Retort No. 3 was fairly successful, whereas Retorts No. 1 and No. 2 and the vertical retort were complete failures. Retorts Nos. 4, 5, 6 and 7, and eventually the Clinchfield retort, were modeled more or less on Retort No. 3, with such changes as seemed desirable in the light of accumulating experience.

Retorts Nos. 4, 5, 6 and 7

These four retorts were the prototypes of the Clinchfield retort described below, and were all modeled on Retort No. 3. In Retort No. 4 the burners were placed in two rows along the bottom of the retort, with flues running ribwise around the retort and opening into a large open space over the whole top of retort. Later the heating system was rebuilt so as to run the flues from either side into two separate parallel sole flues running lengthwise the retort as in the Clinchfield retort shown in Fig. 4 below. This change was subsequently made on Retorts Nos. 5, 6 and 7 and the four retorts arranged as a battery.

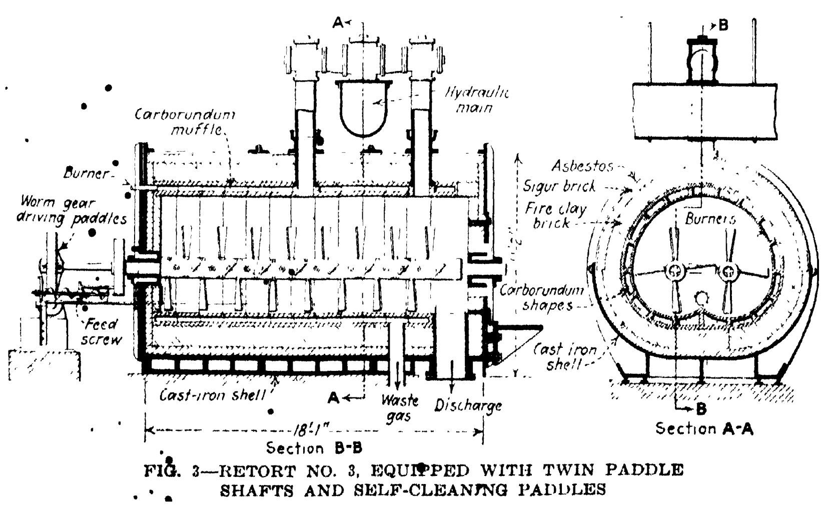

FIG. 3—RETORT NO. 3, EQUIPPED WITH TWIN PADDLE SHAFTS AND SELF-CLEANING PADDLES

Various types of gas offtakes were tried out on Retorts Nos. 4, 5, 6 and 7, but eventually all four retorts were equipped with the scrubber standpipe type, such as shown in Fig. 4.

For discharging the carbon residue, Retort No. 4 was equipped at first with a chute closed by a hand-operated barrel valve. Below the valve the carbon residue fell into a cast-iron cooling chamber, closed at the lower end by a hand-operated door through which it could finally be discharged to a conveyor. As may be guessed, the hand-operated barrel valve soon gummed up and could not be moved. The "Vesuvius" discharge, as later used on the Clinchfield retort, Fig. 4, was finally evolved. This included a pair of breaker arms, overlapping twin screws in a cast-iron casing, with a short vertical chute at the outer end of the screws. The carbon residue brought out by the screws was forced up over a curved floor into a vertical chute and then fell over a dam and down onto a conveyor. By thus forcing the carbon residue up into a short vertical chute, a partial seal over the ends of the discharge screws was secured. Retorts Nos. 5, 6 and 7 were also equipped with this discharge apparatus, and, very unfortunately, it was adopted for the Clinchfield plant.

Retort No. 9

Description of Retort No. 8 will be omitted, since this retort was never set up at Irvington, although it was designed.

Retort No. 9 was built of steel with steel supports which were designed to take care of the expansion of the metal. The essential features of this retort are shown in Fig. 5. Unfortunately, the supporting of the steel retort proved insufficient when the retort was heated and it soon warped so that the paddles dragged on the sides of the retort and it could not be further operated.

The failure of this retort discouraged further large-scale experiments with metal retorts, but small-scale tests have been continued and are still in progress at Clinchfield.

The Clinchfield Retort

The evolution of designs along the general lines of Retorts Nos. 3, 4, 5, 6 and 7 culminated in the Clinchfield retort, adopted for the commercial Carbocoal plant at Clinchfield, Va. This retort is shown in Fig. 4. Including furnace, machinery, etc., it is roughly 37 ft. long, 12 ft. wide and 27 ft. high, in over-all dimensions, while the heart-shaped muffle is 7 ft. 4 in. maximum width and 16 ft. long. The muffle is built of carborundum shapes, the total weight of carborundum per muffle being about 5 tons. The muffle is supported on fireclay saddles 18 in. apart, and is heated by two rows of ten open pipe burners supplied from a fuel gas manifold placed in a tunnel underneath the retort. Air for combustion is drawn through a recuperator, the amount of air to each burner being controlled by a damper block near the burner. There are ten combustion flues on each side of the retort, each set of flues leading to a common flue running lengthwise the retort on top, as shown in Section *B-B* of Fig. 4.

The paddle shafts and paddles are of cast steel, each paddle held in place by a single steel stud bolt passing through the shaft, the shaft being recessed for the nut and reinforced under the nut.

The carbon residue discharged from the retort falls down a vertical chute about 7 ft. long, at the bottom of which a pair of breaker arms crush the larger pieces of material so that it can be handled by the discharge screws. There are two of these screws in a common casing. At the outer end of the screws the carbon residue is pushed up a curved surface into a short vertical chute, and finally falls over a dam formed by cutting away the sides of the vertical chute. (This arrangement is known as the "Vesuvius discharge." See

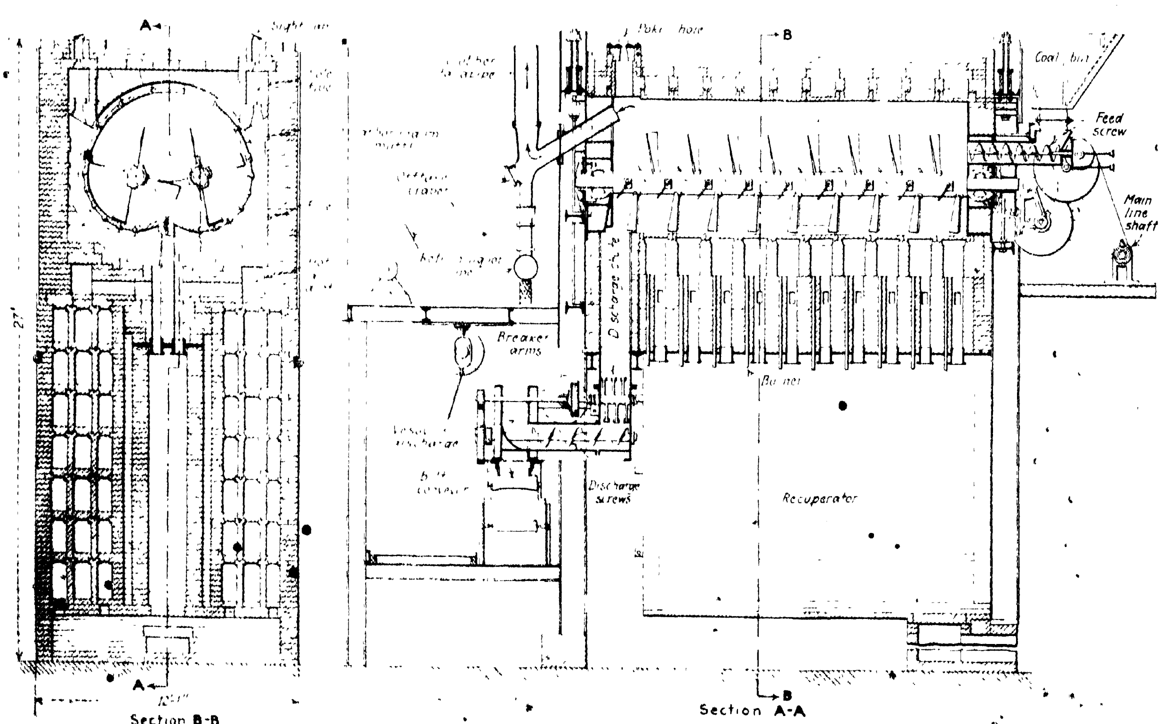

FIG. 4—CLINCHFIELD PRIMARY RETORT

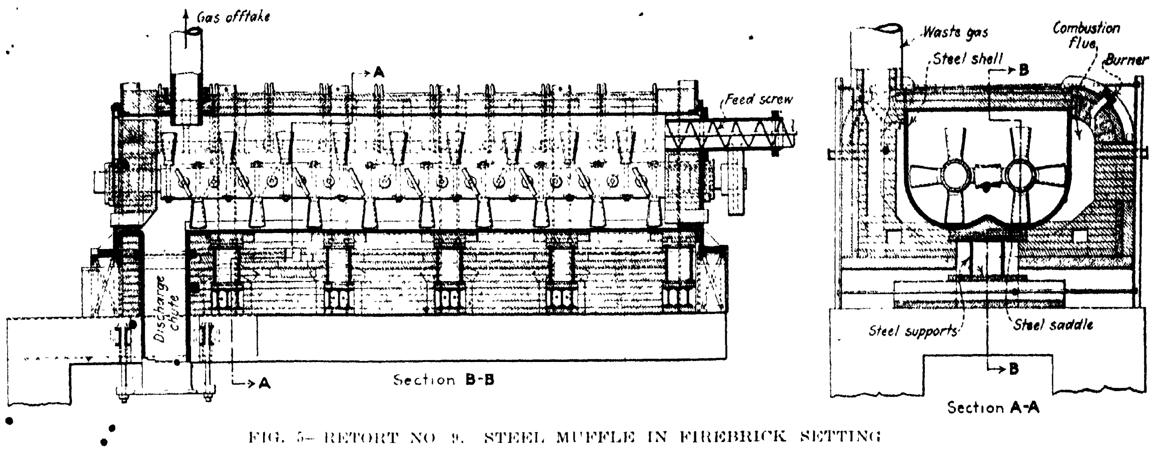

FIG. 5—RETORT NO. 9. STEEL MUFFLE IN FIREBRICK SETTING

reference to it in a later paper.) The carbon residue is carried away by rubber-covered conveyor belts.

The end plates of the muffle are suspended from the top, with means for adjusting the tension on the suspension bolts as the muffle changes elevation due to expansion of supporting masonry. The end plates, however, cannot be raised or lowered independently of the muffle.

At Clinchfield these retorts are built in four batteries of six retorts each, the feed ends of retorts are turned toward each other and four retorts are fed from a common coal bin. The feed screws and paddle shafts for twelve retorts are driven from a single 50-hp. motor.

In a subsequent paper in this series of articles the performance of this retort at the Clinchfield plant will be discussed and further details of construction mentioned. From perusal of Fig. 4 it will be evident that the retort was a costly one to build and those familiar with the art of low-temperature carbonization will readily foresee some of the operating difficulties encountered with this retort at Clinchfield.

Steel Plate Primary Retort

There are several reasons why a metal retort for carbonizing coal at low temperature would be desirable, the chief of these being, of course, the high heat conductivity of a metal compared to a refractory. One of the most serious difficulties in the project of low-temperature carbonization lies in the matter of heat transfer to the coal mass.

It was thought that if a muffle were built of rather thin steel stock, the temperature necessary in the heating flues might be so low that no damage would be done to the muffle. As a test of this idea, a heart-shape muffle was fabricated of half-inch boiler plate, with round about steel ribs, the joints in the muffle being welded. The muffle was essentially of the same dimensions as the carborundum muffle in Retort No. 4 and was substituted for this muffle.

The experiment was unsuccessful, the steel muffle soon warping until it interfered with the paddles.

Briquetting Carbon Residue

In the foregoing pages we have described various commercial retorts built and tested at Irvington, and the retort adopted for the Clinchfield plant. The evolution of a workable retort, however, was only a first step in the production of a marketable, smokeless fuel. The original plan of briquetting the carbon residue while it was still in a plastic condition proved unfeasible, and attention was next turned to methods of briquetting the non-plastic residue. This problem proved to be one of some difficulty also. The carbon residue as it comes from the retort, containing, say, 10 to 12 per cent of volatile, is a light, friable form of semi-coke, which readily begins to burn when exposed to the air. Various systems of handling this material were tried out at Irvington, including pan conveyors, air-jet conveyors and steam-jet conveyors.

The air-jet conveyor (Sims) was out of the question, due to its aggravating the fire trouble and to the difficulty of collecting the coke dust carried out of the bins by the air. The steam-jet was more satisfactory, but was also impractical on account of the very high steam consumption. The pan conveyor was satisfactory so far as carrying the carbon residue was concerned. It was found that the carbon residue could not be stored for longer than about an hour unless it were very thoroughly quenched, and if this were done the wet material would clog the grinding mills. The ground material, however, could be stored for some time without catching fire.

The system finally used at Irvington was to grind the hot, dry carbon residue within an hour or so after it left the retort. The ground material was then stored in a steel bin until briquetted. The ground carbon residue shows little or no tendency to burn explosively, even when ground so that 50 per cent of it will pass a screen of 100-mesh per linear inch.

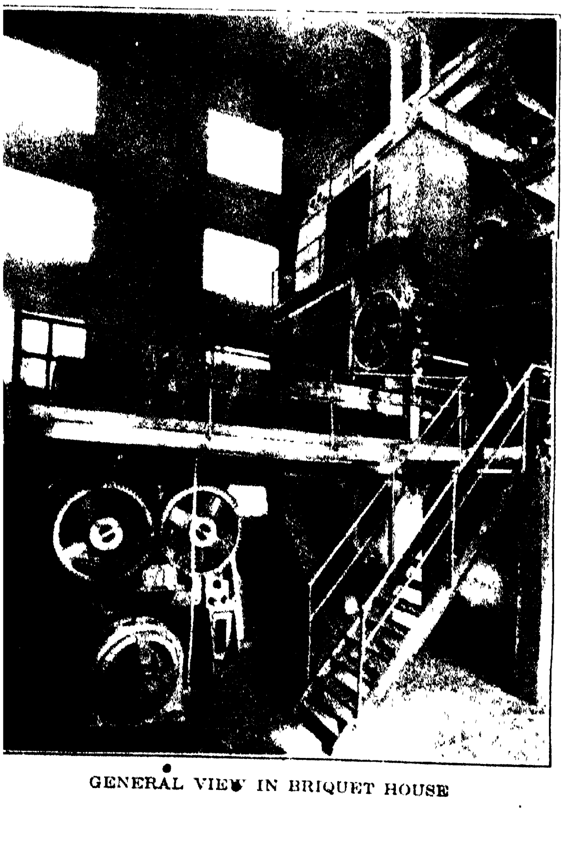
The first step in briquetting carbon residue is the proper grinding of the material. There were tried out at Irvington a Williams hammer mill, a roll crusher and a Mashek hammer mill. None of these was satisfactory. The roll crusher did not give a satisfactory distribution of screen sizes in the ground material, and the hammers on the hammer mill would not stand up under the abrasive action of the carbon residue. The problem of grinding carbon residue was not solved at Irvington. At the Clinchfield plant hammer mills were installed, despite the Irvington experience, and when these failed completely, ball mills were used successfully.

After proper grinding it is a simple matter to flux the ground carbon residue with a binder and briquet it. The percentage of binder required is higher than for coal, and the pressure required in the press somewhat greater, but in general the same principles apply. At Irvington a Belgian type roll press was used successfully. This press formed thin oval briquets, however, and it was thought that a more nearly

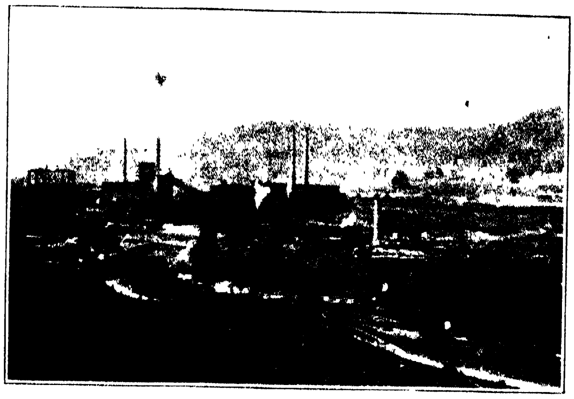
spherical briquet was preferable. To meet this requirement a Komarek press was installed. This is a roll press in which flat-link chains run over one of the rolls, between the rows of briquet dies, yielding oval briquets with flat ends. This press gave good results in the experimental plant at Irvington. It was less successful at Clinchfield when used there later, due to excessive wear on the liner chains.

The briquets formed from carbon residue with suitable binder can be shipped and marketed. They are not smokeless, of course, and if pitch be used as the binder, the tarry smoke which distills out during the first few minutes on the fire is disagreeable and is likely to cause trouble from fires in the chimneys if used in ordinary househould stoves. After the briquets have been on the fire a few minutes, however, the pitch has distilled out and the briquets then burn slowly and without smoke.

It was recognized at Irvington that although briquetting the carbon residue converted it into a salable product, these raw briquets did not represent an ideal solution of the problem. By heating the raw briquets in a muffle it was found that they could be rendered smokeless and an appreciable yield of byproducts obtained. It was discovered, also, that the carbonizing of the raw briquets at high red heat not only rendered them smokeless by distilling out the pitch, as might be expected, but it also changed the internal condition of the briquets so that a finished briquet has a continuous structure, whereas in a raw briquet there are discrete particles of carbon residue cemented by minute globules of pitch. During carbonizing, the particles of carbon residue link to one another more or less firmly. The Carbocoal briquet is harder and denser than the raw briquet, the shrinkage in volume during carbonization being anywhere from 10 to 30 per cent. It



GENERAL VIEW IN BRIQUET HOUSE



GENERAL VIEW OF CLINCHFIELD PLANT AND VILLAGE

was also discovered that the quality of the Carbocoal is dependent to a remarkable degree on the make-up of the raw briquet. There are apparently several factors involved and it became evident that briquetting carbon residue for subsequent carbonization was quite a different proposition and a decidedly more complex proposition than the mere binding of coal or of carbon residue into raw briquets. During the past 5 years experiments in briquetting and carbonizing have been under way continuously. We plan to publish at some later date a summary of the several hundred experiments completed. Suffice it to say here that we now know the general influence of the following factors in the problem:

a. Coking quality of the original coal.
b. Volatile left in carbon residue.
c. Screen analysis of the ground carbon residue before briquetting.
d. Composition of raw briquet mix.
e. Quality and screen analysis of any raw coal added to raw briquet mix.
f. Kind of binder and melting point of same.
g. Method of fluxing, time in fluxer, temperature in fluxer and water in final briquet mix.
h. Temperature of material fed to press.
i. Kind of press used, pressure, shape of briquet, condition of briquet surface.
j. Rate of heating briquet in secondary retort, final temperature reached, time of carbonization, height of briquet charge in the retort.
k. Time between discharging of briquets from secondaries and quenching. Method of quenching.

Not all of these factors are independent of one another, but it is necessary to control each of them within certain ranges which it has been our endeavor to determine.

Carbonizing Raw Briquets

Several commercial retorts for carbonizing briquets were built and tested at the Irvington plant during the 6 years of experimental work there. It was found that ordinary D-shape gas retorts would carbonize the briquet satisfactorily in a few hours, but it was difficult to charge and discharge such retorts with briquets. A Glover-West vertical retort was built and tried, but the column of briquets in this was too high and the briquets at the bottom of the column were crushed before they hardened.

Inclined retorts were finally tried and operated with some success, although there was always some breakage in charging the retorts, and it was very seldom that a charge of carbonized briquets would roll out of a retort without poking it with rods. The secondary retort finally adopted for the Clinchfield plant was of rectangular section, divided into an upper and a lower chamber

by a silica brick partition, each chamber being roughly 4 ft. high, and 25 ft. long, 14 in. wide at the charge and 16 in. wide at the discharge end. The retorts were heated by gas burners, set at the top of vertical flues, the waste gases passing through a recuperator system before entering the main flue.

The main trouble with these retorts was that the column of briquets was too deep and the breakage of briquets was excessive. When the raw briquets were exceptionally good and other conditions very favorable, these secondary retorts would yield fair results, but under the normal conditions of operation they were outside the limits of workable equipment. The experience with these retorts at Clinchfield will be mentioned in a subsequent paper.

Summary

We have described briefly in the foregoing pages the general features of the several primary or low-temperature retorts built and tested at Irvington, N. J., and the evolution of the Clinchfield retort. Mention has been made of the methods tried out in handling the carbon residue from the retorts and the means used to convert it eventually into a fuel resembling anthracite in properties. It has not been possible to make this paper a record of the very numerous minor experiments which were carried out with the low-temperature retorts and with other equipment developed for the Carbocoal process. The program at Irvington also covered a considerable number of subjects connected more or less closely with the Carbocoal process but which lie outside the scope of this paper.

The experimental work at Irvington had been under way for a little over three years when the U. S. Government decided to finance a commercial Carbocoal plant at Clinchfield, Va. The Irvington plant had grown to be a semi-commercial plant meanwhile, with several primary retorts, a complete system for handling the carbon residue, grinding and briquetting equipment, two benches of secondary retorts, screening and loading station for Carbocoal, byproduct units and tar distilling plant.

At the time the Clinchfield plant was constructed complete solutions had not been found for all the problems in the process, but it was thought that the equipment which had been developed would be reasonably satisfactory in a commercial plant. We shall close this paper with a summary of the data available for design of a commercial Carbocoal plant at that time. In the third paper of this series we shall discuss the operation of the Clinchfield plant which was presumably built on the basis of Irvington experience.

In setting down the following items of data available for plant design, it must be recognized that personal judgments come into play. We have endeavored here to reflect the general opinion of men who actually directed operation at Irvington, checking these general conclusions against the operation records.

1. The equipment for handling the coal up to the primary retort, including the track hopper, apron conveyor, Williams hammer mill, bucket elevator and distributing conveyor was entirely satisfactory. The general scheme was adopted for the Clinchfield plant and proved satisfactory there.

2. The proposition of using twin paddle shafts and self-cleaning paddles to avoid plugging of primary retorts by plastic coal mass was entirely satisfactory and subsequent experience at Clinchfield has confirmed the correctness of this design.

3. The single helical screw, carrying coal into the retort above the paddle shafts, was found satisfactory. The same arrangement later proved efficient at Clinchfield.

4. Carborundum blocks proved satisfactory as material for primary retorts at Irvington, being strong enough to permit relatively thin walls and having a high heat conductivity. At Clinchfield later experience has shown that the slow oxidation of the blocks is a serious drawback.

5. The heating system for primary retorts as finally adopted at Irvington was fairly satisfactory, and Clinchfield experience has not added materially to what was known at Irvington. Better methods of heating a primary retort have been developed since Clinchfield construction, however, as will be shown in subsequent papers.

6. As a result of many experiments on discharge mechanisms for the primary retorts, the scheme finally adopted was to drop the carbon residue down a vertical chute onto a pair of revolving breaker arms, below which a pair of helical screws carried it out several feet and forced it up over a dam. This mechanism later proved to be a failure.

7. It was known at Irvington that a carbon deposit formed on the inner walls of the primary retort and that eventually this deposit hardened so as to interfere with the paddles. It was thought, however, that a retort would not have to be cleaned out more than twice a year. This conclusion proved erroneous in Clinchfield operation.

8. It was found at Irvington that the gas offtakes from the primary retorts would plug and had to be reamed out at frequent intervals. This reaming proved troublesome at Clinchfield later.

9. At Irvington the air jet conveyor was shown to be worthless for carrying carbon residue and the steam jet conveyor was found to be extravagant of steam. The pan conveyor gave some trouble mechanically, but was otherwise successful. None of these schemes was adopted for Clinchfield.

10. It was shown at Irvington that it is impractical to store warm unground carbon residue, since it soon begins to burn. This experience was disregarded in Clinchfield design.

11. It was shown at Irvington that hammer mills are not satisfactory for grinding carbon residue. This experience was disregarded in Clinchfield design.

12. The method of proportioning the raw briquet mix worked out at Irvington included a slide-gate with a drag chain conveyor for the ground carbon residue and a weir for the molten pitch. This arrangement was used at Clinchfield. It never gave real control of the proportions of carbon residue and pitch.

13. The Komarek briquet press with flat-link chains running between the dies was adopted at Irvington. It operated well at Clinchfield, but the wear on the chains was excessive.

14. The link-chain cooling conveyor for briquets as they came from the press was satisfactory at Irvington and later proved so at Clinchfield.

15. It was known at Irvington that raw briquets must be handled with reasonable care to avoid excessive breakage. This information was disregarded in Clinchfield design.

16. It was known at Irvington that raw briquets when stored in bins have a tendency to stick together and refuse to flow out of the bin through a discharge door. Large storage bins were installed at Clinchfield.

17. The inclined secondary retorts developed at Irvington were not entirely satisfactory there and proved less so at Clinchfield. It was very rarely that a charge of finished briquets would roll out of the retorts without considerable poking and the breakage was usually high. Several of the factors affecting the quality of the Carbocoal were recognized at Irvington.

Contraction and Shrinkage of Aluminum Alloys

As the result of an investigation of the contraction and shrinkage of aluminum alloys conducted by Robert J. Anderson, metallurgist, at the Pittsburgh, Pa., experiment station of the Bureau of Mines, it has been shown that contraction of a series of forty alloys varied from 0.96 and 1.80 per cent, depending upon conditions, and that it is advisable to make accurate pattern allowances for the various alloys in casting practice.

A Longer College Course for Engineers

By F. E. Turneaure

Dean, College of Mechanics and Engineering, University of Wisconsin

[Apropos recent editorial comments on engineering education for metallurgists and chemists, and correspondence on those matters published in the department headed "Readers' Views and Comments," the following exposition of the longer engineering curriculum by Dean Turneaure will be illuminating. It was contributed to the December, 1922, issue of the Bulletin of the Society for the Promotion of Engineering Education.]

IT SEEMS to me that, broadly speaking, the most important problem before the engineering schools is the old one: What are the requirements which should be met by the engineering school, and how should the curriculum, teaching staff, etc., be organized to meet these requirements? In suggesting this fundamental problem, I am of the opinion that it has never been adequately studied, and that a properly constituted board can do a great deal to crystallize opinion in regard to this very fundamental problem. Perhaps a statement of some of my own notions will explain what I have in mind as to past defects and future possibilities.

Qualifications Demanded for Engineers

First, in regard to requirements of the present day in the matter of the school training of engineers: In attempting to answer this question, a great many fields of engineering activity should be considered. The question cannot be answered by the broad statement that engineers should be trained like lawyers or doctors and that, engineering being a profession, the training should preferably consist of general college courses followed by professional courses requiring altogether 6 or 7 years. I think a certain class of engineers and educators is inclined to consider that this is the ultimate and inevitably correct solution. There are, on the other hand, a good many teachers and also engineers who consider that for many lines of practice a 4-year school period is long enough and that the young man will do better to get into practical work than to remain longer in college. I have myself seen considerable evidence of the truth of the latter position. It is my belief that the technical requirements of an engineer and an engineering education vary over a comparatively wide range and that a careful study of the situation with especial reference to this point will give us some really useful information.

I think this problem can be divided into two parts: (*a*) How much general education should an engineer have, and (*b*) How much technical education should he have? In attempting to answer these questions, all branches of engineering practice should be thoroughly studied and very definite inquiries should be made of men in practice who understand exactly what is wanted. The actual needs of men in various lines of engineering activity should be considered. Highly technical specialties should be recognized as such, and the proportion of engineers in various kinds of work should be information of [illegible]nificance in this connection.

A[illegible]illustration of what I have in mind, consider th[illegible] of highway engineering at the present time. A [illegible] number of men are required at this work, and a large percentage of these men are not engaged (at least for many years) in a kind of work which involves a very large amount of technical schooling. The work of the young engineer, from the technical standpoint, is quite simple, and likely to be so for many years—in fact, the business phase of the work is perhaps of more importance than the engineering phase, especially for men in the more responsible positions. It is true, also, that for certain classes of work an engineer should have a very thorough training in structural design or in bituminous pavements, geology, etc., but the number of men needed for this kind of work is comparatively small, and some of this highly specialized work may well be considered in the category of specialization.

Minor Branches of Engineering

Then there are many other varieties of engineers whose preparation does not need to be highly technical, such as the operating engineers, contracting engineers and, in a sense, railroad engineers. In the various industries there are certainly many lines of work where the technical requirements are not high but where business sense and judgment count more. I believe an effort should be made to analyze requirements very thoroughly along some such line as above suggested.

It is my belief that the time has arrived when it may be expected that any young man desiring to enter any engineering employment, however simple, ought to secure, if possible, a college training of 4 years in length. With the tremendous increase in the high school and college attendance throughout the country and the increasing ease with which young people can secure a college education, I believe that such an education should be required of any young man who goes into a business or profession where he expects, sooner or later, to exert considerable influence with his colleagues or with the public. A college education no longer is an uncommon thing. I am impressed with that fact in looking over our recently published alumni directory and noting the large number of university graduates located in all the smaller cities and many of the villages throughout the state. This number is bound to increase, and an engineering representative of the highway commission in any neighborhood, or the village or city engineer, should be a man who can acquire a standing with the best in the community. It is my belief, therefore, that a 4-year college course of some kind should be the minimum set before the young man as a preparation for any line of engineering.

It is quite true that the technical requirements of some lines of work may be met by means of short courses of 2 or 3 years in length, and that question was discussed by our faculty some years ago. We reached the conclusion that 2-year courses would well satisfy the technical requirements for quite a variety of employment, but did not consider it the function of the university to establish such courses.

Four-Year Course the Minimum

If it is decided that a 4-year college course is sufficient to meet the requirements for general education plus minimum technical requirements, then the problem resolves itself into that of determining the higher technical requirements and how they are to be met in the school: whether by a combination liberal arts course plus graduate work in engineering, or by a 5- or 6-year combination course carrying some engineering work throughout the period. At present our standard 4-year

engineering course as given in most schools is, in my judgment, of a quality which is neither hay nor grass; it cannot be considered a course for a broad education, neither can it be considered a very satisfactory course for those desiring the most advanced training. The first-named objection is more serious than the latter, because a student desiring advanced technical work can get it in graduate study; but the lack of breadth cannot be so easily remedied by the individual student.

To indicate more clearly what I have in mind as to the direction for this phase of the investigation, I might outline what seems to me to be a fairly good solution, and the reasons therefor.

Pre-Engineering Courses

In brief, this would consider a 4-year engineering course (or pre-engineering course) which would be very general in its character. It would contain a large amount of work of general educational value, such as history, economics, language, science, chemistry, physics, mathematics and mechanics, also the elements in applied work in the usual branches of engineering. Such a course I would consider the minimum requirement for any young man who desires to enter the industries or any field of engineering whatever; and for many lines of work it would be a satisfactory preparation. It would also furnish a sufficient foundation in mathematics and science to enable a man of real ability to advance himself in almost any line of engineering activity, even where a longer course of training would be preferable. By the elimination or postponement of a very considerable amount of technical studies, now included in the regular 4-year course, such a course as above indicated could be made quite satisfactory from the standpoint of general education and, on the whole, much more satisfactory than a 4-year course in a college of liberal arts such as would be elected by students planning on an engineering course later. At least it would meet the needs of a great many more students, and I am inclined to think that it would be the best course for practically all.

The 4-year course as above indicated should lead to a degree (such as the B.S. degree), without special designation. Then those students who desire a more thorough engineering education should secure it by further study, either in the form of graduate work or fifth- and sixth-year courses leading to an appropriate second degree. These advanced courses would be well organized, and would be taken by a very considerable number of students, as they would contain a good share of the material now included in our senior year. They would naturally be taken by all students desiring to enter the research field and those aiming to become fairly well posted in any special line. I should suppose that from 25 to 40 per cent of those finishing the 4-year course would continue for a fifth or sixth year, the percentage depending, of course, quite largely upon the curriculum adopted.

Among the advantages of such a scheme as above suggested are possibly the following:

1. It requires all engineering students to secure a much broader general education than is now the case, while at the same time it includes a sufficient amount of fundamental technical work to satisfy the requirements in many cases.

2. It furnishes the well-organized technical work for special and advanced students which will encourage students of ability to thoroughly prepare themselves for research and special work of various kinds. Graduate courses in engineering will be much better organized than is now the case.

3. It is a better arrangement than that frequently proposed of requiring a 2- or 3- or 4-year college course before admission to the engineering school. In any pre-engineering course, a considerable amount of mathematics and science must be required in order to save time, and pre-engineering courses under the control and advice of the engineering faculty can be better adjusted to the students' need than when otherwise administered.

4. It would I believe, solve the problem of the 4-year course, against which so much criticism is directed.

5. It would tend to eliminate from the more advanced and technical work students who are unfitted for such work while at the same time capable of becoming successful engineers in certain lines of employment. With the very great numbers now attending engineering schools, a relief of work in the senior and junior laboratories would be very acceptable in most cases.

There are, of course, many other phases of this study but I believe the very first thing to be done is to determine upon some reasonable solution of the problems above discussed. Engineering faculties are, I feel sure, quite capable of determining upon details and methods of teaching. They are also, in most cases, in very close touch with practicing engineers among their alumni and include among their members many men with considerable engineering practice. I do not believe, therefore, that it is necessary to go far into details. On the other hand, it is true that engineering teachers are, as a whole, quite concerned over the situation, and are prepared to follow the lead of a strong report which will clearly set forth requirements and a way to meet them under the conditions actually existing in the majority of engineering schools. We, I think, are ready to move, but we want to move in reasonable unison, and in a direction that it will not be necessary to retrace in the near future.

European Attempts to Number Steel

Progress Made by Switzerland, Germany and France Toward Standardization

A RECENT conference held in Washington discussed the desirability and possibility of devising some system of numbering whereby kinds or qualities of steel can be designated by code numbers. Lawford H. Fry, of the Standard Steel Works Co., presented a résumé of European practice, as revealed by correspondence with various foreign organizations. It appears that Switzerland, Germany and France have made some attempts to establish such a code.

The Swiss system attempts to show the content of the carbon and of the principal alloys by using the chemical symbol of the elements and adding to each a figure showing the mean percentage. Thus a carbon steel with 0.25 to 0.35 per cent carbon has as its symbol C2n. The suffix "n" shows a maximum allowable content of 0.07 per cent phosphorus and 0.06 per cent sulphur. If the steel is given the symbol C2s, the maximum allowable is 0.04 per cent phosphorus and 0.03 sulphur. If the symbol is written C2 without suffix, neither may exceed 0.02 per cent.

In this manner all steels are classified on the basis of their chemical properties. It does not take into con-

sideration either the manufacturing process (whether open-hearth, electric or crucible) or the use to which the metal is designed to be put—such as rail steel, firebox steel, and so on.

For a chromium-nickel steel with 0.25 to 0.40 C, 2.5 minimum Ni and 0.60 to 0.90 Cr, the symbol is 3-Ni30-Cr8. In the alloy steels the C for carbon is omitted, but the first figure "3" shows a mean carbon content of three-tenths per cent, the Ni30 a mean nickel content of 30-tenths per cent and the Cr8 a mean chromium content of eight-tenths per cent. Following the chemical composition symbols a note is added when the steel is to be annealed or treated, and in the latter case the minimum tensile strength in kilograms per square millimeter is given. Thus the complete designation of the above nickel-chromium steel would be 3-Ni30-Cr8 treated to 80. The standard sheets show the yield point, elongation and notch toughness corresponding to this tensile strength, and these may, if desired, be added to the symbol in ordering.

If the symbol gives no information regarding the condition, it means that it will be received after ordinary slow cooling from the last forging or rolling process. When special attention must be given to other properties, the person specifying must select the correct alloy by reference to the standards. Thus a steel with 80 to 90 kg. per sq.mm. tensile strength (115,000 to 130,000 lb. per sq.in.) can be met by a plain carbon steel. However, if elongation must not be less than 12 per cent, then a nickel steel would be chosen (3-Ni30 treated to 80). If in addition a yield point of at least 85,000 lb. per sq.in. is required, "3-Ni30-Cr8 treated to 80" may be selected.

It appears to Mr. Fry that the Swiss code is open to serious objections unless it is used in close connection with a series of standard specifications. If a symbol standing alone is to be interpreted, misunderstandings may occur. For example: Since the average carbon content is rounded off to the nearest one-tenth per cent, the symbol C4 may indicate a carbon steel with a carbon range from 0.30 to 0.40 per cent (mean 0.35), or with a range from 0.39 to 0.49 per cent, (mean 0.44). Further, in the steels now listed the manganese content varies without any indication of this being given in the symbol.

The system is stated to be capable of indefinite expansion and yet to indicate definitely the steel desired. It appears to Mr. Fry that in practical work much confusion will occur unless the symbols are used in direct connection with the standard sheets.

GERMANY

An industrial standards committee has issued a bulletin covering steels without alloys and untreated. Seven grades are listed, for which tensile strength and elongation in the annealed condition are specified by arbitrary numbers with the prefix St.

Designation	Tensile Strength, Kg. Per Sq. Mm.	Elong. in 100 Mm., Per Cent
St. 0	Not specified	Not specified
St	34-44	25
St. 1	34-42	30
St. 2	42-50	24
St. 3	50-60	22
St. 4	60-70	17
St. 5	70-80	12

The German committee doubts whether it will be practicable to classify all steels in a continuously numbered series. It will possibly be desirable to separate carbon from alloy steels so that a basic number related to the carbon content can be carried through while the alloy steels receive a distinguishing mark.

Another interesting attempt has been made by the Bavarian Motor Works'.[1] It follows somewhat the American Society of Automotive Engineers' system. The first digit of their number corresponds to the degree and kind of alloy; thus, 1 represents carbon steels, 2 a low alloy, 3 represents nickel steels, 4 nickel-chromium, 5 nickel-tungsten, 6 high chromium—greater than 1½ per cent. The second digit represents the carbon content in tenths of 1 per cent. Finally letters are added, designating the quality: *a* for first class construction steels, *b* for standard open-hearth steel, and *c* for ordinary commercial steel of moderate strength. Low-alloy steels of class 2 are all presumably of *a* quality, for these letters are replaced by others representing the alloy content. By this scheme steel 12b represents a plain basic open-hearth steel, S and P up to 0.05 per cent, containing 0.16 to 0.25 per cent carbon. On the other hand, 21m/s is a silico-manganese steel (Mn over 1 per cent, Si over 0.5 per cent), with carbon up to 0.15; 42a will be an electric furnace nickel-chromium steel, Ni about 3.5 per cent, Cr about 1.5, C, 0.25 and Mn 0.4 per cent.

Such a scheme is said to be coming into use by the German Society of Automotive Manufacturers, but evidently a user of the code must always have an explanatory table showing composition limits and physical properties.

FRANCE

A permanent commission for standardization in France has issued a series of specifications for carbon steel bars, blooms, billets and slabs in five classes of steel. No chemical composition is given, but in each specification the steel is divided into grades according to the minimum tensile strength. The numbers of the specifications, the class of material and the grades are shown below:

A-1-UF. Ordinary stock material. Grades by minimum tensile strength of an annealed bar: 35, 40, 48, 55, 70 kilograms per square millimeter.

A_2-2-UF. Material furnished in heat-treated condition. Grades by minimum tensile strength of bar from material as furnished: 35, 40, 48, 55, 70, 80, 90, 100 kilograms per square millimeter.

A_2-3-UF. Material to be heat-treated after delivery. Grades by minimum tensile strength from heat-treated bar: 60, 70, 80, 90, 100, 115 kilograms per square millimeter.

A_2-4-UF. Low-carbon steel for carburizing. One grade only, no tensile.

A_2-5-UF. Low-carbon mild steel. Grades by minimum tensile strength of annealed test specimens: 35, 38 kilograms per square millimeter.

The steels meeting these five specifications are to be marked to indicate the material as follows:

(1) The number of the specification as given above.

(2) A letter indicating the method of manufacture: M—acid open hearth (Martin). C—crucible. E—electric. B—bessemer acid. T—basic open hearth (Thomas).

(3) The number showing the minimum tensile strength specified.

The French Standards Commission, following the advice of the Committee of Arts and Manufacture consulting with it, accepted the principle that symbols in code should not be used. It has therefore arranged its system to designate beyond question a definite grade of steel covered by a complete specification. It appears to Mr. Fry that this principle is sound. A code which is designed to be extensible must lead to ambiguities as it is drawn out to cover new steels.

The Nature of Solid Solutions

Solid Solutions Usually Exhibit Space Lattices of Their Dominant Member, Slightly Distorted—In Some Systems the Transition Zones Show Two Co-existing Lattices Where Atoms of Each Constituent Replace the Others in Its Own Space Lattice

BY EDGAR C. BAIN, M.SC.

General Electric Co., Cleveland, Ohio

ENGLISH-SPEAKING scientists have chosen the words "solid solution" to denote the specific state of association of two or more substances entirely homogeneous in the solid. The name has points of merit, even though in some respects the properties of solutions are not apparent. The fact that such solids are capable of a considerable change in constitution and temperature without entailing any phase change urges us to this name. The German "mischkristall" gives us a fine conception of the condition structurally, but unfortunately is translated[1] literally "mixed crystals," which does not give us a picture of the solid solution, but more probably calls to mind a mechanical mixture of two kinds of crystals. If we translate "mischkristall" as "miscible crystal" we get a very clear picture of the condition. Recent investigations of metals with the X-rays[2] have brought out much information about the arrangement of the atoms themselves and the relation of this arrangement to the properties of the aggregate, and naturally the baffling condition of solid solubility has attracted extensive study by this same means. To this end many crystallograms of a great variety of solid solutions have been made in the author's laboratory and the results are here described.

The atomic arrangements of the metals and metalloids have been largely investigated and are shown in Fig. 2, with models of the space lattice types. The reader is requested to refer to this figure as various metals are mentioned.

BINARY SOLID SOLUTIONS

Many pairs of metals are entirely miscible in the liquid state in all proportions, just as are alcohol and water. Some others have such partial miscibility as have phenol and water, the solubility of A in B and of B in A increasing continuously with elevation of temperature. Rarely we find metals which exhibit little or no miscibility in the liquid state.

But there is the more interesting phenomenon of solid miscibility, very frequent in metals but having fewer examples in the non-metals and compounds.[3] With proper annealing two metals which have this mutual property become chemically homogeneous and resemble a pure metal; under the microscope the polyhdral grains are as uniform as a pure metal. But they freeze over a range instead of at a constant temperature; this is a concomitant with the phenomenon of "coring," a complex condition which will be discussed in a second contribution.

It was early discovered[4] that *when a metal A acts as a solvent in taking up metal B in the solid state, the atoms of B replace atoms of A in the A space lattice.* This substitution seems invariably to alter the parameter of the lattice slightly, but never its type until such a quantity is added as will exceed the limit of solid solubility, at which point a new lattice is formed compatible with the increased atomic ratio. This new phase usually involves the formation of a compound, and the metal begins to assume the lattice characteristic of the compound. (We shall consider later the few cases where no new phase appears between pure A and pure B, series known as continuous solid solutions or isomorphous series.)

As examples of limited solubility in the solid state we have investigated tin, zinc, manganese and aluminum as solutes in copper as solvent; cadmium and zinc in silver; tungsten, molybdenum, chromium and manganese dissolved in iron. The following data refer to the completely annealed or homogenized condition.

COPPER-ZINC[5]

When 30 per cent of the atoms of copper (face-centered cubic) are replaced by zinc atoms to form common alpha brass, the lattice is stretched so that

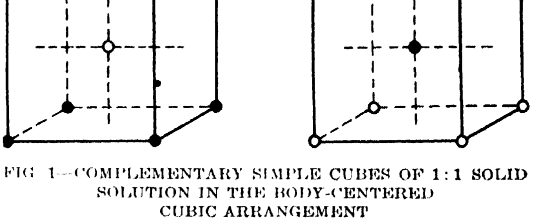

FIG 1—COMPLEMENTARY SIMPLE CUBES OF 1:1 SOLID SOLUTION IN THE BODY-CENTERED CUBIC ARRANGEMENT

Light circles represent one kind of atoms and solid spots the other

the fundamental cube edge a is increased from 3.60 Angstrom units to 3.68 A.u., a linear change of nearly 2.2 per cent or a volume increase of 6.7 per cent in the unit cube. Computing density from atomic spacing and absolute weights of atoms (the hydrogen atom weighs 1.662×10^{-24} grams) we obtain the value of 8.54 as compared to the actually determined value[5] of 8.533.

When zinc is added to copper in excess of about 35 atomic per cent the face-centered lattice is inadequate to absorb it even at room temperature—the electronic distributions or interatomic forces find equilibrium in a body-centered cubic structure. The alloys in the narrow range around equal atomic proportions can be cooled slowly to room temperature, giving what appears under the microscope as homogeneous grains of β brass. The X-ray study shows that the large grains thus produced are truly of a single lattice. The conclusion is then that the structure is as shown in Fig. 1. Either sketch represents the conditions, since the central atoms in one series of cubes build themselves into corners of another series of interpenetrating cubes of exactly the same size. Centers become corners, and *vice versa*, as desired. Further additions of zinc produce a rhombo-

[5] Private communication from F. G. Smith, American Brass Co., Waterbury, Conn.

*hedral lattice and a structure** *which has no ductility* (γ brass). The structure of the limited η series of very rich zinc alloys is what might be predicted. They consist of the hexagonal zinc lattice in which copper atoms replace a few of the zinc atoms. In interpreting these results in terms of α, β, γ and other brasses represented on the equilibrium diagram, it should be remembered that the ranges for the different crystalline types as established by the X-rays do not correspond accurately with the divisions in the ordinary constitutional diagram drawn from thermal and microscopic investigations.

COPPER-TIN

A 90:10 copper-tin bronze has an atomic ratio of 94.98 Cu to 5.02 Sn. The 5 per cent of tin atoms are over two-thirds as effective in stretching the copper lattice in the alpha bronze as the 30 per cent of zinc atoms in alpha brass. The cube edge of the space lattice for copper is elongated from 3.60 to 3.655 A.u., a linear change of 1.53 per cent, or a volume change of about 4.6 per cent. The absolute or theoretical density calculated from atom weights and spacings is 8.955.

It is a rather interesting fact that in the above solid solutions the lattice is always stretched somewhat less than would be expected from a proportional increase in lattice size computed from atomic volume considerations. This indicates a weak but perfectly definite attraction between unlike atoms. For example, the tin atom is 186 per cent larger than the copper atom, but 5 per cent of tin atoms in copper does not increase the average cube 186 × 0.05 = 9.3 per cent (the proportional increase), but by only 4.6 per cent. Again, the zinc atom is 29.5 per cent larger than the copper atom, but 30 per cent of zinc atoms does not increase the lattice size by 8.87 per cent (the proportional increase), but by only 6.8 per cent. It is also apparent that the tin and copper atoms pack more closely—considering the volume of the tin atom—than do zinc and copper.

COPPER-ALUMINUM

A 91:9 Cu:Al alloy has an atomic ratio of 81.2 Cu to 18.8 Al. Incorporation of that amount of aluminum stretches the lattice 0.91 per cent, equivalent to a volume change of 2.8 per cent. The cube edge becomes 3.633 A.u. as compared to the 3.60 for pure copper. Copper and aluminum show a strong attraction in the alpha solution, for we should expect an increase of 7.52 per cent in volume from the substitution of aluminum in 18.8 per cent of the copper lattice points, since the aluminum atom is about 41.0 per cent larger than the copper atom.

COPPER-MANGANESE

Copper-manganese alloys are often represented as an example of the completely miscible isomorphous series, but X-ray examination has shown that some ranges of composition reveal the simultaneous presence of both the lattice type of copper and the lattice type of manganese in a thoroughly annealed specimen. So there is apparently a limit for solubility of manganese in the copper lattice. A normal copper lattice is extended very slightly by the substitution of manganese atoms. When one out of three copper atoms has been replaced by manganese the original cube edge of 3.60 has become 3.615 A.u. Further additions of manganese seem to be rather more effective in stretching the lattice,

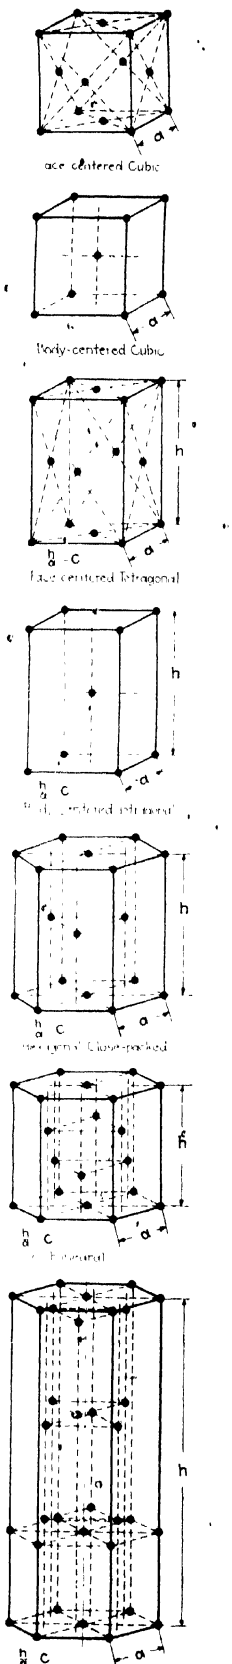

FIG. 2—CRYSTAL STRUCTURE OF SOME METALS AND THEIR ATOMIC SPACINGS

although the change is so small it is difficult to be sure of this fact.

Manganese lattice has not yet been completely deciphered. It has an atomic volume of 7.4, while copper is 7.1. Manganese much more nearly distends the copper space lattice in proportion to its atomic volume than most other atoms; the absolute amount, however, is small, since their atomic volumes are so similar.

SILVER-CADMIUM

If we saturate solid silver with cadmium, we increase the cube edge about 1.1 per cent (a volume change of about 3.5 per cent). This is notably less than the proportional increase due to disparity in atomic volume, as cadmium has an atomic volume 27.4 per cent greater than silver.

SILVER-ZINC

Silver saturated with zinc in the solid decreases the cube edge from 4.06 to 4.005 A.u., a shrinkage of 1.36 per cent, or a volume change of 4.0 per cent. Zinc has an atomic volume only 9.8 per cent less than silver, and this is greater shrinkage than would be expected from the difference in atomic volume. This behavior of the two silver alloys strengthen the idea that there is a mutual attraction between unlike atoms, causing them to pack closer than their separate atomic volumes would warrant.

IRON-CHROMIUM

In iron and chromium we have two metals chemically similar and with atomic arrangement identical in type and differing very little in atomic spacing. We should expect great mutual solubility. As a matter of fact, the alloys resulting from fairly rapid cooling from the melt seem to be all true solid solutions regardless of composition, but there is some reason to believe very prolonged heating at about 1,100 deg. C. develops a new constituent. It is therefore doubtful if the system comprises a continuous series of solid solutions. There is no measurable change in the lattice. The spacings of iron and chromium (2.86 and 2.895 A.u.) are so nearly alike that great accuracy would be required to detect any stretching or shrinking. Very little would be expected.

TUNGSTEN-IRON AND MOLYBDENUM-IRON

These two series, composed of body-centered cubic metals, might be expected to form continuous isomorphous alloys, but both tungsten and molybdenum form the 1:1 compounds WFe and MoFe of a hexagonal type not fully elucidated. Solid iron dissolves a few atomic per cent of both W and Mo, but, strange to say, the space lattice is not measurably altered. The atomic volume of tungsten and of molybdenum is about 10, as compared to 7.1 for iron. The explanation may be that there is an inordinate attraction between these atoms, chemical in nature, which results in the preservation of the smaller iron spacing even in a solid solution. From X-ray examination it appears that very little if any iron can be dissolved in tungsten or molybdenum without the formation of the compound.

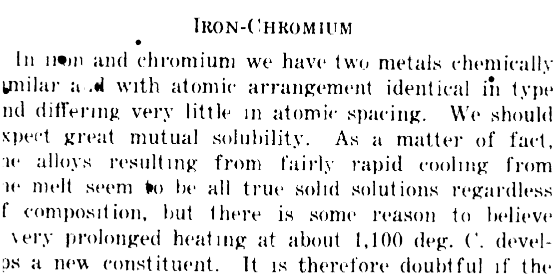

FIG. 3—PROBABLE STRUCTURAL RANGES FOR ANNEALED ALLOYS OF IRON AND MANGANESE

IRON-MANGANESE

Both Gulliver[7] and Desch,[8] quoting Tammann, present the iron-manganese series as an example of complete miscibility in the solid. X-ray diffraction patterns of the series show that three crystal entities in all are present in the system. Fig. 3 shows diagrammatically the regions of each lattice and their overlapping ranges. The alloys examined were cooled very slowly and the data are representative of conditions approaching equilibrium at room temperature. Body-centered ferrite lattice is preserved until about 30 per cent of its points have manganese atoms substituted for the iron. Further additions of manganese develop the face-centered cubic lattice of gamma iron (austenite) and the alloys appear to be wholly of this structure up to about 60 per cent manganese; beyond this point we have the manganese structure appearing, doubtless with iron atoms occupying lattice points in the manganese space-lattice. The purest manganese obtainable has a very complex structure and it has not yet been worked out. It is the author's opinion that if very pure manganese is prepared it may have the body-centered cubic lattice of iron, because X-ray spectrograms made from some manganese-rich alloys produced very definite lines of a body-centered cubic pattern. It may be that the presence of some iron causes the manganese to overcome the action of some slight impurity such as silicon or aluminum, or some other element which induces the complex structure usually found.

Solid Miscibility in All Proportions

It is self-evident that only those elements having the same crystalline type could form a continuous series of solid solutions. If metal A and metal B are of different lattice types and possess great mutual solubility, we must still find solid solutions of both A in B and of B in A. It seems likely that in some ranges of composition these two solutions may exist simultaneously and even have the same composition, the relative amounts of each varying with temperature.

This is certainly the case in the nickel-iron series. Thoroughly annealed specimens are body-centered near the iron end of the series and face-centered in the nickel-rich alloys. Over a great range of intermediate compositions both atomic arrangements are present, the relative amounts depending upon the heat-treatment. Of course, the circumstances are complicated by the allotropy of iron. Early in 1921 the author showed for the first time the allotropic change in iron from body-centered to face-centered atomic arrangement with rise in temperature above 900 deg. C. Following this discovery it was easy to see how the presence of a number of atoms of nickel (whose normal arrangement is that of face-centered gamma iron) can inhibit the transformation to alpha iron, which is body-centered. Why

[7]"Metallic Alloys," G. H. Gulliver, 4th edition, 1921, p. 332.
[8]"Metallography," C. H. Desch, 2nd edition, 1913, p. 401.

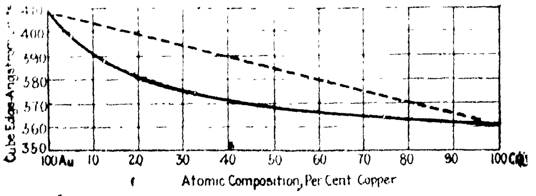

FIG. 4—SIZE OF FUNDAMENTAL CUBE IN THE COPPER-GOLD SOLID SOLUTION SERIES

manganese acts in the same way is not so obvious. The effect of heat-treatment on the relative proportions of the two kinds of solid solutions present in a continuous series is not so marked in the copper-manganese alloys, for instance, as is observed in manganese-iron and nickel-chromium alloys.

It appears that the main reason for classifying these series as continuous solid solutions is the fact that thermal analysis indicates a smooth continuous solidus or liquidus line. If the solubility of A in B cannot quite reach the composition of saturated B in A, the evidence for a region of incomplete miscibility is clear enough, but in some alloy systems they appear to overlap. This leads to an erroneous classification. In the latter group may be put cobalt iron, iron-manganese, indium-lead, cobalt-chromium, chromium-nickel, copper-manganese, manganese-nickel and iron-nickel. It is likely that a suitable etching reagent on well-annealed specimens would reveal two distinct phases under the microscope. Meteoric iron shows two iron-nickel constituents.

But there are quite a large number of truly continuous solid solution series, exemplified by copper-gold, copper-nickel and gold-silver. Several have been studied with X-ray diffraction and are described here. Not all pairs of elements of the same atomic structure form such series of alloys, for many build intermetallic compounds.

Copper-Nickel

The lattice change in these alloys is small but continuous. The contraction due to unlike atoms is so very small as to be immeasurable by the apparatus at present in use. The alloy has already been described from the atomic arrangement standpoint.

Copper-Gold

The series remains perfectly face-centered cubic in structure throughout. The lattice size or spacing changes gradually from copper to pure gold, the cube edge ranging between 3.60 to 4.08 A.u. But this stretching of the copper lattice by substitution of gold atoms is not proportional to the number of gold atoms present. Fig. 4 shows that the alloy is more dense (closer spaced) than the lineal function would demand. It again appears that the unlike atoms attract one another more closely than like ones. Fig. 5 represents the crystalline arrangement of two of the intermediate alloys in comparison with the pure components.

Gold-Silver

Gold and silver have very nearly the same atomic spacing. The whole series has the same spatial arrangement, varying from 4.06 to 4.08 A.u. on the cube edge. There is no measurable departure from the lineal relation between atomic proportion and lattice size.

Molybdenum-Tungsten

This series presents the same aspects as the gold-silver series except that it is of the body-centered cubic type. The cube edge varies continuouslly with composition from 3.143 to 3.150 A.u. Here again we find no measurable attraction of unlike atoms to cause any unexpected lattice size. The inference is that this effect is dependent upon the disparity in atomic volume. That is to say, when large and small atoms are packed in a common lattice, they are drawn more closely than their respective sizes and proportions would indicate, while unlike atoms of about the same size do not show attraction and compression to any extent.

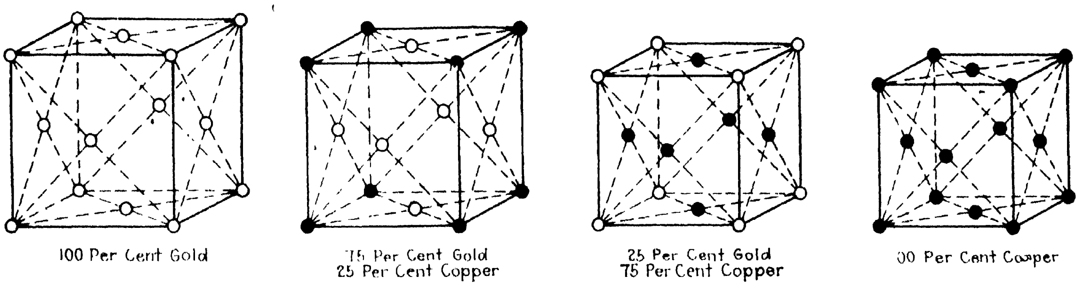

FIG. 5—ARRANGEMENT OF THE GOLD (LIGHT CIRCLES) ATOMS IN SPACE FOR CERTAIN GOLD-COPPER ALLOYS

German Chemical Exports to America

Preliminary returns of Germany's foreign trade in chemicals during the first 9 months of 1922 are given in *Commerce Reports* for Dec. 25, 1922.

The United States purchases of these chemicals for the 9 months included (all quantities in kilos): Alkali metals, etc., 75,800 kilos; white and red phosphorus, 191,300; lactic acid and lactates, 165,600; tartaric acid, 716,100; citric acid, 42,500; crude potash salts, 97,755,000; fertilizer salts, 119,456,900; barium chloride, 285,300; bromides and bromoform, 516,800; ammonium carbonate, 262,600; caustic potash, 4,029,100; pot ashes, 2,087,700; chloride of lime, etc., 3,221,400; potassium chlorate, 1,570,600; sodium sulphate and bisulphate, 5,767,100; potassium sulphate, 45,436,700; copper sulphate, 161,200; alums, 1,576,300; ammonium nitrate, 4,817,700; barium nitrate, 107,800; potassium manganate and permanganate, 228,800; ferricyanides, 114,900; cyanides, 64,300; tartar and tartrates, 443,000; carbonate of strontium, etc., 1,800; zinc salts, 1,029,200; arsenous and arsenic acid, 402,900; magnesium sulphate, 8,303,900; chlorides (calcium, magnesia), 4,448,000; muriate of potash, 102,975,600; ammonium chloride, 1,784,700; potassium and sodium sulphates, 1,062,100; and barium, lead, and nickel compounds, 9,149,800 kilos. The American share of other chemicals exported is not shown in the preliminary official statistics.

Legal Notes

By Wellington Gustin

Public Interest in Every Adjudication Regarding Validity of Patents Emphasized

In a suit brought by the Griscom-Russell Co. against the Standard Water Systems Co. and others, a decree of the United States District Court for the complainant has been reversed by the Circuit Court of Appeals, and claim 8 of patent 1,131,738 for an evaporator was held void for lack of invention, in view of the prior art. (278 Fed., 703.)

The Griscom-Russell Co. charged defendants with infringement of its patent, issued to Reuben R. Row, one of the defendants. The bill charges that the inventor and two other defendants employed by the Griscom-Russell Co. left such employment and associated themselves with the Standard company, with the purpose and intent to injure the Griscom company, by appropriating to themselves and the Standard company valuable data, engineering designs, drawings, etc., which were the property of the Griscom company and that they all conspired together to infringe the letters patent.

The District Court decreed the Griscom company to be the lawful owner of the patent and that the defendants had jointly infringed the patent and that the plaintiff recover profits, gains and advantages; and that an account be stated. An injunction was issued against the defendant company only.

On appeal the Circuit Court of Appeals found no direct testimony of any federation between the individual defendants for the purpose of injuring the plaintiff.

Inventor May Show Limitations by Prior Art

What seemed to weigh most heavily against the defendants, says the court, in this case is the fact that one of them asserted invention to procure a patent which he assigned to the plaintiff, and that, while all of the individual defendants were subsequently associated with their co-defendant, the said co-defendant manufactured and sold devices with the patented improvements embodied therein.

One who asserts and claims an invention and receives a patent therefor is estopped from denying invention, but the court says he is not estopped from showing to what extent his alleged invention is limited by the prior art.

The public is interested in every adjudication with respect to the validity of a patent, and it is the duty of courts having jurisdiction of patent causes to have regard, at all times, of the rights of the public, so that such rights may be rather enlarged than diminished by judicial determination. The public interest in every patent is set out in the case of Hill vs. Wooster, 132 U. S., 693. That opinion emphasizes the doctrine that it is not enough that the thing shall be new, that in the shape or form in which it is produced it shall not have been known before, and that it shall be useful; but it must, under the Constitution and the statutes, amount to invention or discovery. (Hansen vs. Slick, 145 C.C.A., 37.)

Returning to the case at bar, the court says the process of vaporizing water or other liquid to obtain a purer liquid is old. And the apparatus for accomplishing the result desired is old. The claim of the patent is as follows:

"The improvement in evaporating apparatus for obtaining purified liquid, which comprises a containing shell, a door closing an aperture in said shell, a heating pipe structure secured to said door and projecting within said shell, a supporting roller for said structure outside said shell, substantially as described."

The court was of the opinion that there was no invention in the addition of rollers to the evaporator. It says: "The addition of rollers to a desk, in order that it may be moved, so that the carpet could be cleaned under it, was an improvement by the man who added the rollers; but that invention did not add to the dignity of invention or discovery, within the meaning of the Constitution and the laws passed in pursuance thereof, intended to give an inventor an exclusive right for a time, as against the public."

Regardless of the rule that a patentee or an assignee of a patent cannot deny invention, it is the duty of the court to determine lack of invention, where apparent, in order that the public interests may be guarded. Therefore the decree of the lower court was reversed.

Interstate Shipment Is Protected From State Law Until Sale of Original Packages

An interesting point is involved in injunctive proceedings begun in the United States District Court by the Cleveland Refining Co. against W. H. Phipps, director, attacking the constitutionality of an Ohio statute providing for inspection of petroleum products and fixing fees to be charged therefor. The court says that a state has power to enact proper inspection laws and provide for the collection of the necessary expense of inspection and is not required to fix with exactness the fees which will cover such expense, but as applied to articles of interstate commerce the fees must reasonably approximate such cost and not be so excessive as to render the law a revenue measure.

Plaintiff is engaged in the sale and distribution of kerosene, petroleum and their products. It buys in other states, ships into Ohio large quantities of such articles in storage tanks, barrels, cans and packages, and has contracts for such articles which it is bound to consummate.

Plaintiff contended that the inspection fees were excessive, that they interfere with interstate commerce and are an unlawful import duty upon goods shipped into Ohio from other states and as such the law violates the sections 8 and 10 of Article I of the U. S. Constitution. And so the District Court held. The court found the fees charged for inspection were yearly increased until they doubled the cost, and that there was no distinction made between oil produced in the state and that brought in from other states.

The court says that where goods are transported into one state from another in original packages, interstate commerce therein is not completely terminated, and they are protected by the commerce clause of the Constitution against excessive inspection, until after their sale at the point of destination within the state.

Now the fees prescribed by the statute were beyond the cost of legitimate inspection to determine the quality of the articles inspected, and the act is therefore not only a police measure but a revenue measure also. Such cost by necessary operation unduly burdens and obstructs the freedom of interstate commerce and as such commerce cannot be separated from the interstate shipments, the whole tax is void.

Vapor-Recompression Systems for Evaporators—I

An Unprejudiced Survey of the Advantages and Shortcomings of Regenerative Evaporation — A Technical History of Its Development and an Analysis of Recorded Data on Test Runs*

By W. L. Badger
Professor of Chemical Engineering, University of Michigan

IMAGINE a simple evaporating device, with liquid boiling in it at atmospheric pressure. Also assume that it is heated by steam at 10 lb. gage (240 deg. F.), that no heat is lost in heating feed, in radiation or in any thick liquor drawn off, and that the condensate leaves at the temperature of the boiling liquid. To evaporate 1 lb. of water will take 970.4 B.t.u., and 1 lb. of steam will give up 980.4 B.t.u. A very slight change in our fundamental assumptions will make the two exactly equal. Then, what is happening really comes down to converting 1 lb. of steam at 240 deg. and 10 lb. gage to 1 lb. of steam at 212 deg. and atmospheric pressure.

Now if the hot condensed water is returned to the boiler without loss, we will have to add 980.4 B.t.u. to regenerate a pound of heating steam. But the pound of atmospheric vapor formed contains 970.4 B.t.u. more than the condensate. Why not, then, merely add 10 B.t.u. by compressing the steam instead of 980 to raise more steam? By this line of reasoning many times as much evaporation could be obtained per pound of coal burned than by raising steam direct, even after allowing for all kinds of losses.

Much has been written on this subject, but the articles have usually had a partisan bias. It is the purpose of this paper to give as nearly as possible an unprejudiced survey, and show the faults as well as the advantages of the system.

Historical and Descriptive

The first record of vapor recompression is a patent[1] by Pelletan in 1840 (36).† His apparatus is shown in Fig. 1. A pan m has a cover T supported by counterweights. Heating is done by two coils g. High-pressure steam is admitted by E and F to the injector nozzles B. These draw vapors from the pan through pipes a and compress them in the coils. This apparatus was unsuccessful, partly due to faulty nozzle design and partly to the very low boiler pressures then carried.

The Piccard-Weibel System

In 1874 Koerting (25) suggested the use of steam-jet nozzles for drawing non-condensed vapors from the steam spaces of evaporators, and mentioned that these vapors together with the steam which operated the nozzle would be compressed enough to be returned to the steam space (28). Nothing was done, however, till the advent of the Piccard-Weibel system in 1879 (30). It received considerable notice through the '80s (6, 11, 15, 26, 27, 40, 43, 44). Fig. 2 shows the system applied to a single effect evaporator. The reciprocating compressor C takes vapor from the dome A and compresses it to be used in the steam space. This figure shows how early it was realized that in such installations all possible heat must be saved, for the heat interchanger S is provided to heat the feed by the heat of the condensate. If the compressor C were to be steam driven, the exhaust was best utilized in a triple-effect as shown in Fig. 3.

This system was employed in several salt plants in France and Austria, and in a few sugar mills. It was installed in the mill at Pohrlitz in 1882. Weibel (43) reports that the mill of 225 tons per 24 hours sent about one-third of the juice to the thermocompressor evaporator. This was a triple of 150, 50 and 80 sq.m. respectively (vertical tubes). The compressor was 31.5x19.5 in. (fifty strokes per minute), took steam at 59 lb. gage and exhausted at 6 lb. gage. It took vapor at atmospheric pressure from the first effect and compressed it to 6 lb. One lb. of boiler steam theoretically should have compressed 2.5 lb. vapor and furnished 1 lb. of exhaust, which would have evaporated 3 lb. in the triple effect, making a total of 5.5 lb. evaporated per pound steam. A very complete test was later made on this system (31, 42) which showed actually 4.4 lb. of water evaporated per pound of steam. While the Piccard-Weibel system was retained for a considerable time in salt works which had ample water power, it never gained a foothold in the sugar industry because of the excessive size and, at that time, rather poor design (11) of the reciprocating compressors needed.

The Nozzle Compressor

In the later developments, two lines of work have been followed—the nozzle compressor and the turbo-blower. Along the line of nozzle developments the principal place is held by Prache and Bouillon, who in 1905 developed a steam jet nozzle (102), such as is shown in Fig. 4, and which was claimed to be far superior to any other. The nozzle alone cannot make a practical device, and an explanation which anticipates the theory must therefore be introduced.

In order to obtain a satisfactory capacity of the nozzle, the pressure range through which the vapor is compressed must be small. Neglecting minor factors, this pressure range is made up of two parts: (a) The

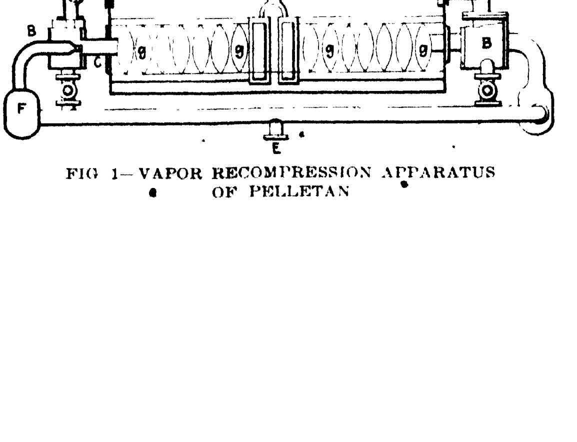

FIG 1—VAPOR RECOMPRESSION APPARATUS OF PELLETAN

*Read before the American Institute of Chemical Engineers at Baltimore, Dec. 9, 1921.

[1]In (12) this date is given as 1834

†Numbers in parentheses refer to bibliography to be published at end of Part II. Numbers below 100 are articles and above 100 are patents.

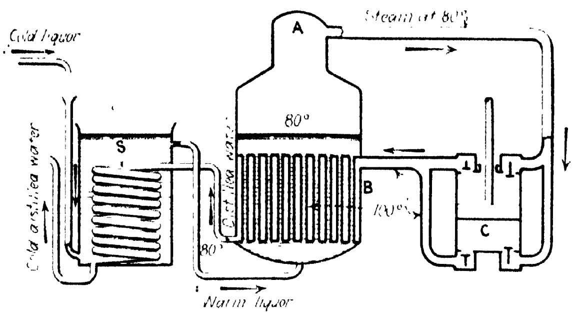

FIG. 2—PICCARD-WEIBEL SYSTEM

elevation in boiling point of the solution, (b) the working temperature drop. The first part cannot be changed, but its effect may be minimized by confining the concentrated liquid to one part of the apparatus; for when an ordinary evaporator works continuously, the whole body is full of liquid at the final concentration. The second factor is, of course, within the control of the designer; but the smaller it becomes the larger must the apparatus be for a given performance. If an evaporator could be designed with an unusually high coefficient of heat transmission, an evaporator for a given duty could operate on a smaller temperature drop than usual without increase in size. Hence the features to be noticed in the recent developments are (1) isolation of the more concentrated parts of the solution, and (2) attempts to increase the heat transmission coefficient.

Prache and Bouillon (or as later organized, La Société d'exploitation de procédés evaporatoires système Prache et Bouillon) first developed the evaporator shown in Fig. 5 (4, 5, 36, 101, 114, 123, 133). Here the liquor space of an ordinary vertical tube evaporator is divided by partitions, P, which extend some distance above the upper tube sheet and also completely divide the liquor space below the tube sheet. Each compartment has its own downtake n, and in the center of each downtake is a pipe O leading to the next compartment. Thus a part of the liquid is continually being passed from compartment to compartment, being finally withdrawn from 7. In this way the solution of highest boiling point is localized in the last compartment and only a part of the heating surface is handicapped by this loss in temperature drop.

The steam space is not divided. Therefore, if the vapors are compressed enough to give the desired working temperature drop for the dilute liquor, the compartments containing concentrated liquor will have a smaller temperature drop. But it is just these compartments which need a larger working drop than the others, because of the effect of their increased viscosity and density on heat transfer. If, on the other hand, the vapor is compressed sufficiently to give a satisfactory working temperature drop for the last compartment, it will result in a range of compression too great to be economical for the others.

A Horizontal Tube Evaporator

Prache and Bouillon later devised another evaporator which was to minimize the effect of boiling point and also increase the heat transfer coefficient. Fig. 6 (4, 38, 134) shows this evaporator, consisting of several compartments side by side, each containing inclined tubes with liquor inside, and arranged in series as to liquor feed. All the compartments discharge into a common header, which is, however, provided with partitions to keep the liquor from each compartment separate from the others. A wide tube E for recirculation is provided at the bottom, and means (not shown) are also provided for transferring the liquid from compartment to compartment. Cold feed from A first passes through the preheater B, then by pipe C to the evaporator, circulating through each compartment and finally leaving at F. Vapors from all the compartments collect in I, are compressed by boiler steam in the nozzle H, and go from compartment to compartment in pipes K. Here evidently the amount of compression for all the vapors is sufficient to overcome the elevation in boiling point in the last compartment.

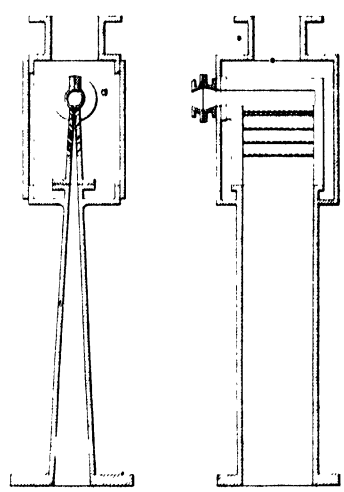

FIG. 4—PRACHE AND BOUILLON NOZZLE

Since the compression is done by a steam jet, there is a continual supply of steam to the apparatus above that which can be condensed by evaporation. Hence

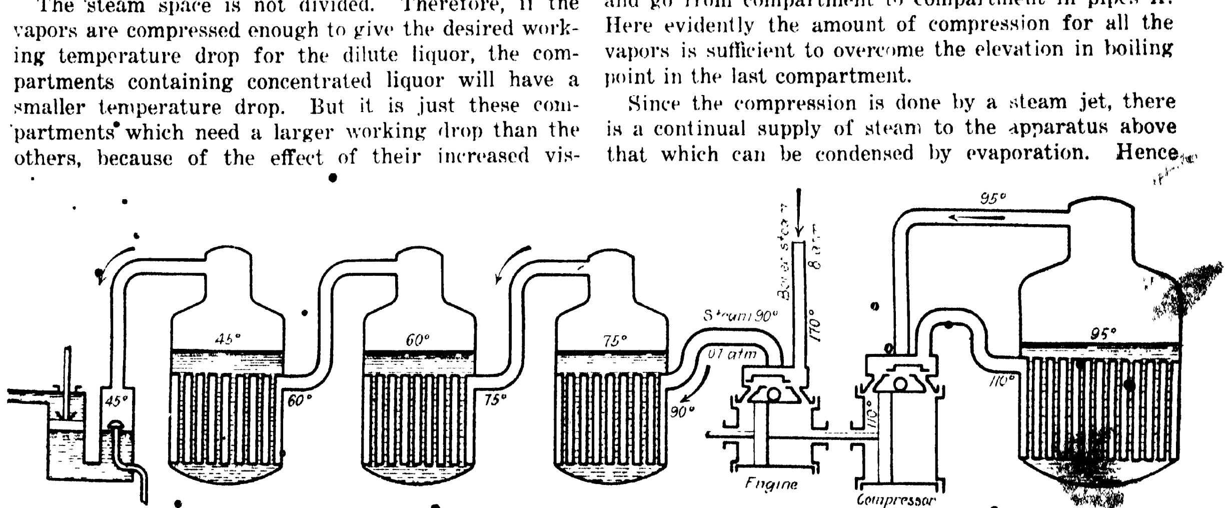

FIG. 3—PICCARD-WEIBEL SYSTEM USING COMPRESSOR EXHAUST

there is a pipe from the steam chamber *I* to the preheater *B*, and from there to an exhaust or to a condenser. The apparatus works in single effect; the compartments differ only in the concentration of the liquid in them, and there will be little drop in pressure along the pipes *K* leading steam from compartment to compartment. The statement is made (4) that the heat transmission coefficients obtained in this evaporator are about double those of an ordinary evaporator. The same writer states that at that time (1916) about seventy-five Prache and Bouillon plants were in operation.

A similar evaporator patented by these workers has the compartments superimposed in one common shell. Fig. 7 (104, 117, 139, 144).

Recently a nozzle as applied to evaporators has been developed by de Baufre at Annapolis (13, 39, 107, 109, 110, 111, 145), and is shown in Fig. 8. In ordinary operation, high pressure steam is expanded through the orifice *B* and nozzle tube *C*. Vapor from the evaporator is drawn in through the inlet, and the mixture of

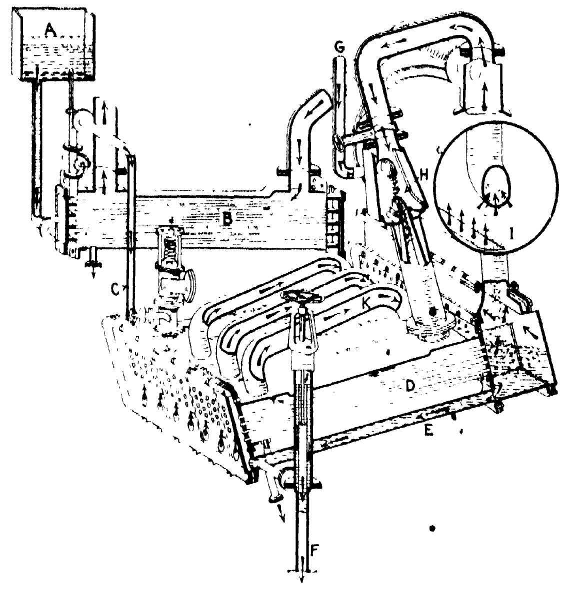

FIG. 6—PRACHE AND BOUILLON HORIZONTAL TUBE EVAPORATOR

compressed vapor and expanded high-pressure steam is discharged through *K* to the evaporator coils.

Nozzle Performance and Design

The performance of nozzles has been studied and some results reported. Eslancher (17) has reported data on the Prache and Bouillon nozzle which have been copied several times (55, 38). From these data Fig. 9 has been drawn. This shows the ratio of (pounds vapor) to (pounds high-pressure steam) for different steam pressures, vapor temperatures and temperature drops. By temperature drop is here meant the difference between the temperature of the steam in the heating space and the temperature of the boiling liquid. It will be noticed that the capacity of a nozzle falls off rapidly as the working temperature drop increases and as the pressure range through which the high-pressure steam is expanded decreases. It is obvious why the working temperature drop for such systems must be held below 10 deg. C.

De Baufre's nozzle has also been tested (13, 39). The data are represented in Fig. 10. The curve for nozzle tip No. 2 is reproduced as Curve 2 in Fig. 11. Curve 1, Fig. 11, is obtained from Fig. 9 for 175 lb. steam (the conditions under which de Baufre's nozzle

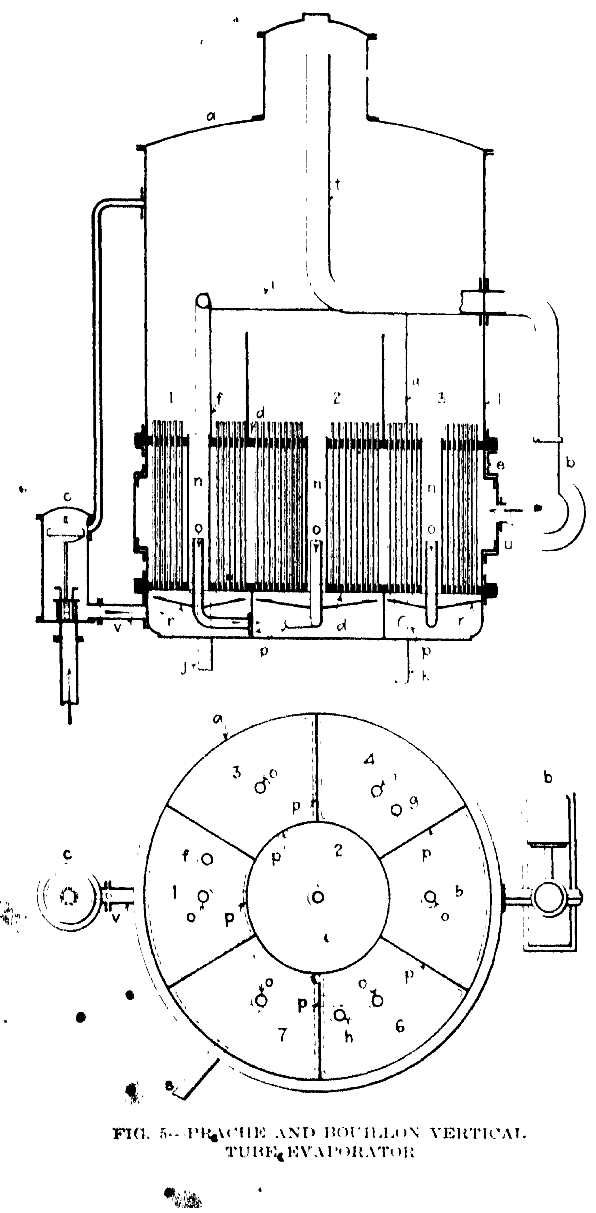

FIG. 5—PRACHE AND BOUILLON VERTICAL TUBE EVAPORATOR

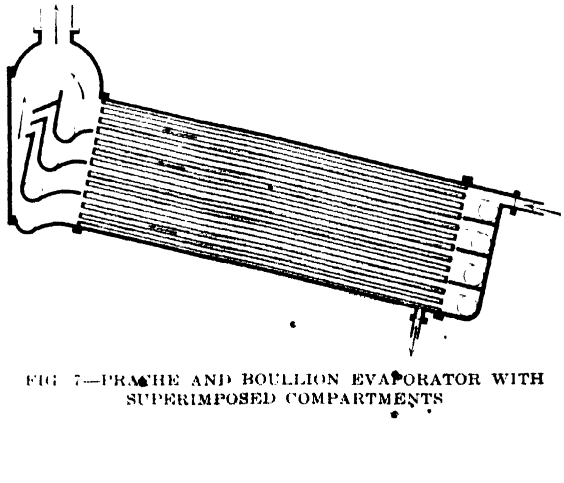

FIG. 7—PRACHE AND BOULLION EVAPORATOR WITH SUPERIMPOSED COMPARTMENTS

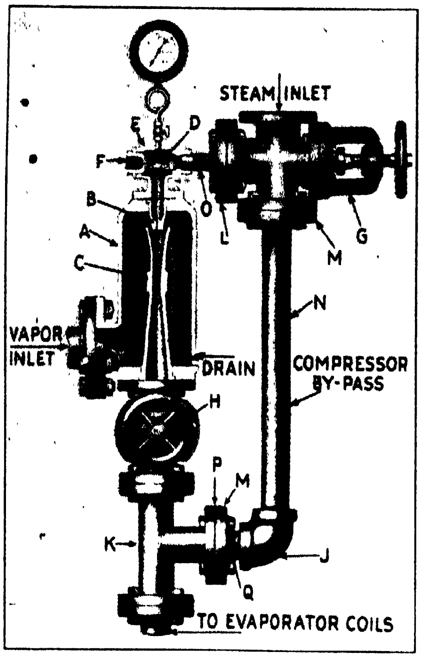

FIG. 8—THE DE BAUFRE NOZZLE

is tested). There have been a number of patents involving the use of nozzles about which there is little or no information available (112, 120, 121, 125, 131, 138, 147, 139).

TURBO-BLOWER DEVELOPMENTS

The other direction in which developments have been made is in the use of a turbo-blower. This has been universally used instead of a reciprocating compressor, in spite of its lower mechanical efficiency, because it can be built in large capacities without excessive size, and because it gives a compressed steam free from oil. The combination of a turbo-blower and an evaporator

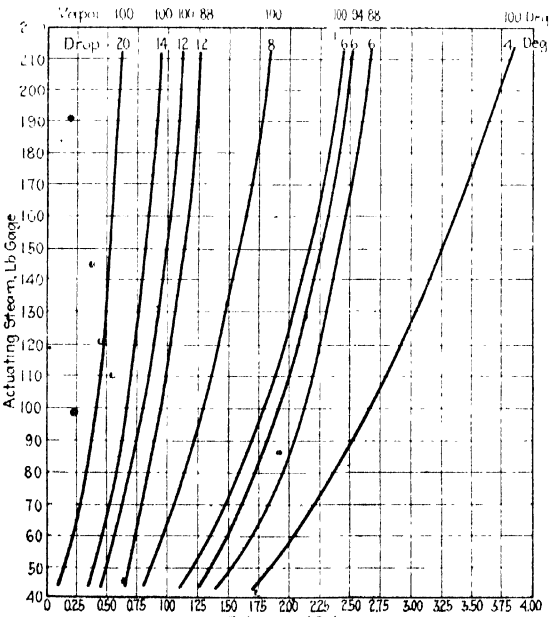

FIG. 9—PERFORMANCE OF PRACHE AND BOUILLON NOZZLE

has been given various proprietary names, such as "auto evaporator," "heat pump," etc. They are rather popular at present especially in Germany. (See 12, 16, 21, 38, 45.)

A well-known series of patents are those taken out by Soderlund and Boberg and assigned to the Techno-Chemical Laboratories, Ltd. (London) (2, 37, 105, 106, 108, 127, 128, 137, 141, 142). They have attempted both to isolate the effect of elevation of boiling point and to get a higher coefficient. This latter has been accomplished in their patents by imitating film evaporators of one type or another. For instance, in the evaporator shown in Fig. 12 (37 and 108), a high coefficient is supposed to result from liquor trickling down the sides of the tubes, distribution being through the device i (shown in the insert) hung in the tops of the tubes. Feed enters the heat interchanger (being preheated by condensate entering at d), and goes to chamber 2, is circulated by pump 4 to chamber h. Vapors are withdrawn from k, compressed by the blower 5, and returned to m. In Fig. 13 (106, 128, 137) high coefficients are obtained by showering the

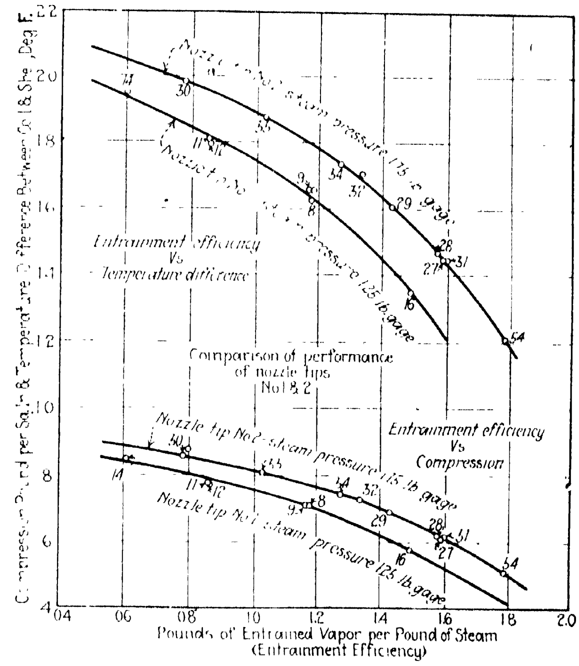

FIG. 10—PERFORMANCE OF DE BAUFRE NOZZLE

liquid over horizontal tubes somewhat as in the Lillie evaporator; and at the same time an isolation of the effect of elevation of boiling point is obtained by running a series of bodies, vapor being stepped up by intermediate compressors to give the proper working temperature drop in each effect. Liquid is fed at 6, preheated by condensate in 7, and fed through float valve 21 into the liquor compartment. It is circulated over the tubes by pump 22, and a part is withdrawn from the first body by pipe 31 to the suction of pump 32 on the second body. The same system is repeated as often as desired. Partitions like 35 on the first body prevent too great mixing of the concentrated liquor falling from the tubes with the thinner feed. A turbo-blower 25 takes vapors from the body and compresses them sufficiently to give a working temperature drop, and also to overcome the elevation in boiling point of the liquid being boiled. The patent claims expressly

call for a working temperature drop of not over 3 deg. C. (5.4 deg. F.). Hence some type of film evaporator must be used, otherwise hydrostatic head would use up all the available drop. Part of the vapors go to the tubes of the first body, part to compressor 29, where they are given additional compression to correspond to the increased elevation of boiling point in the second body, and so on. The patent covers the same principle applied to vertical evaporators like Fig. 11, and also cases where compression is accomplished by nozzles.

There are a number of other patents covering similar devices (113, 115, 122, 124, 132, 143, 146). In general, however, a patented or special apparatus is not necessary. A nozzle or turbo-blower may be adapted to any ordinary commercial evaporator (providing the proper precautions are taken to insure the necessary conditions for satisfactory operation). Such an installation is shown in Fig. 14. The only installations on which actual working data have ever been published are those in which there is no special feature in the construction of the evaporator itself. No information has been published to indicate that the various special and patented designs are successful or practical or necessary.

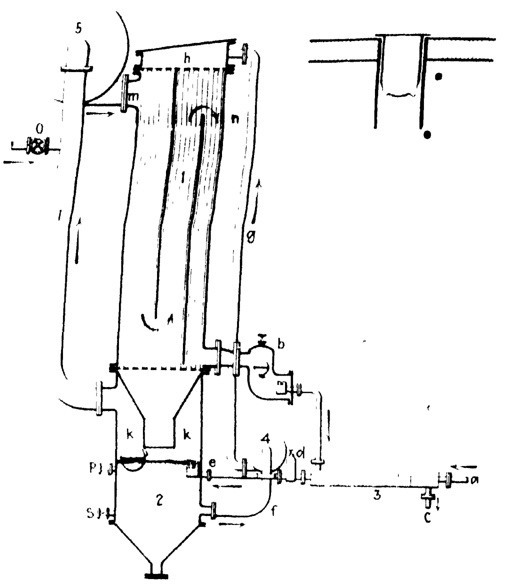

FIG. 12—VERTICAL SODERLUND AND BOBERG EVAPORATOR

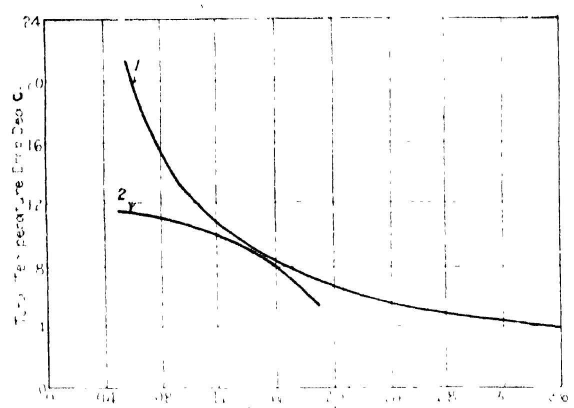

FIG. 11—COMPARISON OF NOZZLE PERFORMANCE USING STEAM AT 17[illegible] LB.

Tusschen (41) and Carlsson (8) have reported results obtained on a small installation built by A. G. Kummler and Matter, Aarau. It evaporates NaOH solution. The same evaporator is described below by Wirth (46) (Apparatus A). A test by Stodola of Zurich Polytechnic showed 36.2 to 37.7 lb. evaporated per kilowatt-hour. Losses, which had to be covered by the direct addition of live steam, amounted to 12.4 per cent, of which 10.7 per cent was heat lost in thick liquor. This was not recovered because the solution could be used hot in the next step of the process. During these tests the elevation of boiling point was 3.6 deg. F. at the start and 12.6 deg. F. at the end of a batch.

Ombeck (29) reports tests on an **evaporator** with vapor recompression. **The apparatus** made distilled water **for ice.** The evaporator is not specially described, except that it had 1,260 sq.ft. of heating surface. Vapor was compressed with a Rateau turbo-compressor. Raw feed water was softened and then preheated in a heat interchanger using the condensate as a source of heat. The principal results, abridged and converted to English units, are shown in Table I.

Runs 8 to 10 were made immediately after installation, runs 1 to 7 after 2 months' operation, and then runs 11 to 15 after cleaning. "Compressor efficiency" is the theoretical work of adiabatic compression divided by the actual power input.

It should be noted that the efficiency of the compressor increases, but the evaporation per kilowatt-hour decreases, as the temperature drop increases. In some cases live steam had to be added to make up for losses in radiation, hot condensate, etc.; but in some cases the

superheat from compression furnished more heat than was lost, so heat had to be discarded from the system by blowing off steam. It should also be noted that this is one of the simplest cases possible; boiling a non-scaling solution of low specific gravity and viscosity and with no elevation of boiling point.

Wirth (46) has given details of a number of installations. A summary of his data will be found in Table II.

There is no special description of the evaporator construction. From the illustrations they seem to be ordinary vertical-tube evaporators with turbo-blowers.

Wirth is connected with A. G. Kummler and Matter

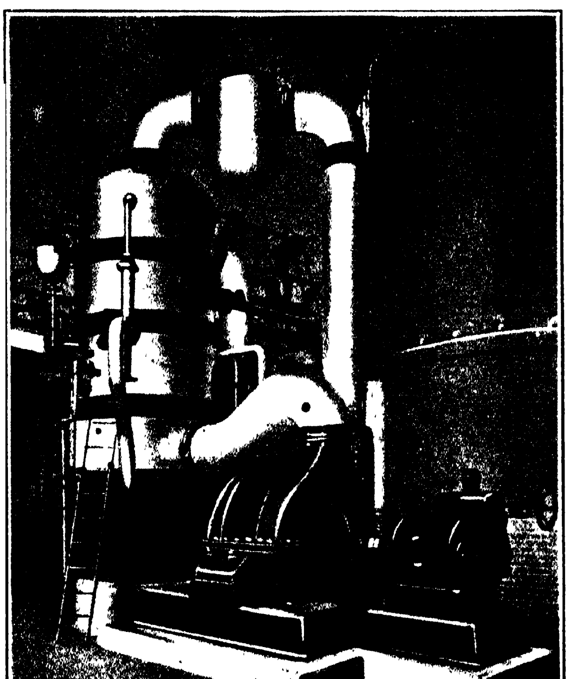

FIG. 14—VERTICAL TUBE EVAPORATOR WITH TURBO-BLOWER

Case *E* is mentioned as the lowest practical rate for thermocompressor operation. Its small rating per square foot evidently means a very small temperature drop. Evaporator *F* has three bodies, all in series as to liquor and in parallel as to vapor. The compressor is in two parts; one part takes vapors from all three and compresses to give the temperature desired for steam to the first two. It delivers some of this steam to the second part, which compresses further for the third body. Mention is also made of a milk evaporator, working with a boiling point of 50 deg. where the heat of compression more than covered the losses so that heat had to be rejected.

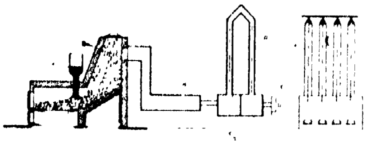
Part II of this series, which will appear in a subsequent issue, gives attention to the general theory of design and construction, together with a comparison of operating economies with single and multiple effect evaporators.

Erosion Cavities in Limestone Deposits

The limestones of the Shenandoah Valley of Virginia and West Virginia are characterized by numerous solution cavities brought about by surface or subterranean stream erosion, states the Bureau of Mines. The quarryman's difficulty is due to the occurrence, even at considerable depth, of erosion cavities, not in the form of open spaces, but filled with red clay. These clay masses are troublesome, and their removal is costly. The problem is of general interest to all limestone quarrymen, for erosion cavities are characteristic of limestone deposits, though they are not generally developed as much as in the district under consideration. Some form extensive caverns in which part of the dissolved calcium carbonate has been redeposited as stalactites and various other ornate forms. Some of the caverns have been illuminated and opened to the public as commercial enterprises. In a few instances the cavities constitute a commercial asset in the valley, yet from the quarryman's point of view they are a decided disadvantage, for they constitute one of his hardest problems. A discussion of stripping problems in limestone quarries in the Shenandoah Valley is contained in Serial 2401, by Oliver Bowles, mineral technologist, which may be obtained from the Bureau of Mines, Washington, D. C.

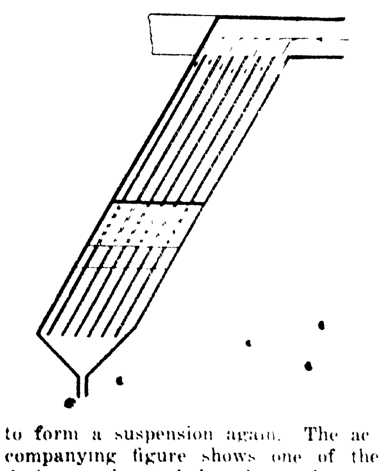
Recent Chemical & Metallurgical Patents

Production of Metallic Arsenic—J. L. Cullen, assignor to the United States Smelting and Refining Metals Co., has patented a process for producing metallic arsenic from the oxides obtained in the metal-refining plants. The present method of distilling mispickel in clay retorts is dangerous. The new method consists in passing vaporized arsenic oxides over red hot charcoal or coke.



Referring to the diagram, (1) is a furnace into which arsenic oxide is fed from a hopper (2), and after volatilization it passes through tower (3) packed with hot coke. Reduction takes place and the gases are cooled in pipes (4) and collected in bags (5). A fan (6) may be used to control the flow of gases. (1,433,533. Oct. 30, 1922.)

Separation of Dust From Gases—N. C. Christensen, Salt Lake City, Utah, has patented an apparatus for settling finely divided solids and liquids out of suspension of gases. The principle upon which this apparatus is based is that settling takes place rapidly if there are no eddy currents in the gas as it is moving along a pipe or in a gas that is still. The apparatus consists then essentially of means of producing a steady flow of gas currents. The inventor also claims that once settled out the solids or liquids can flow with the gases along tubes properly inclined and not be stirred up so as



to form a suspension again. The accompanying figure shows one of the designs submitted by the author to produce a steady flow of gases through the apparatus. The inclined passageways produce both a lateral and a vertical or longitudinal counter flow, and this combination is of great importance in effecting the settling of very finely divided dust. It is claimed that this apparatus will permit the doing away with any filtration of effluent air and thus much simplify present installation. (1,434,090. Oct. 31, 1922.)

American Patents
Issued Dec. 19, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met.* readers. They will be studied later by *Chem & Met.*'s staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

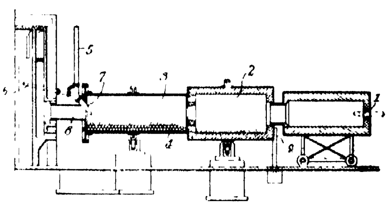
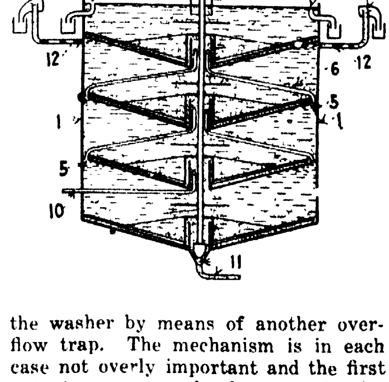
Apparatus for the Production of Sodium Sulphate—M. A. Laury has developed a mechanical furnace for producing salt cake (sodium sulphate) and muriatic acid from niter cake (sodium bisulphate) and salt (sodium chloride). The apparatus is shown in the accompanying diagram and consists essentially of an oil burner (1) supplying heat to a rotary kiln. (2) Here the reaction takes place and there is no balling up of the product because of the fact that it is dried very completely in chamber (3), which is a ball mill. Niter cake and salt are fed into the chamber through leads (5) and (6) in proper proportion and the mixture is ground up and preheated in the ball mill before being introduced into the rotary furnace. The gases of combustion together with hydrochloric acid gas escape at (8) through appropriate ducts and the hydrochloric acid gas is absorbed from the waste gases in the usual manner. Finally the sodium sulphate passes out of the furnace at (9). Sometimes it is found desirable to insert some iron balls in the rotary furnace chamber, but this is usually not essential. The combustion chamber, it will be noticed, is fed on cracks so that it may be rolled up to the rotary and rolled away when the rotary needs relining or cleaning. Trouble with mechanical furnaces in the past has usually been that the charge balls up badly and therefore the reaction does not take its ultimate course. This process is said



to overcome the difficulty by preheating in the ball mill. (1,435,930. Nov. 21, 1922.)

The Counter-Current Washing of Finely Divided Solids—N. C. Christensen, Salt Lake City, Utah, has patented a counter-current washing device. The accompanying diagram shows substantially the principle of the washer. It is based on a tray principle, the various sections of the tray being either horizontal, in which case the solid is moved toward the center by means of plows, or inclined, as in the diagram, in which case the solid flows by gravity toward the center. The thickened pulp moves through a tool then to the next lower compartment and meets there an upcoming current of liquid. It will be noted that the upper tray, onto which the mixture of solids and mother liquids is first pumped, is separate from the rest of the washer and the wash water finally overflows at a point just below the level of the top tray. This permits the separation of the wash liquor from the mother liquor, which is frequently desirable. The solids then continue to settle out of the wash liquor on each of the succeeding trays and are washed as many times as there are trays. Finally, they are discharged from the bottom of



the washer by means of another overflow trap. The mechanism is in each case not overly important and the first patent covers merely the general principle involved. (1,434,089. Oct. 31, 1922.)

German Patents

*For complete specifications of any German patent apply to the German Patent Office, 97 Gitschinerstrasse, Berlin, Germany.

Blue Vat Dye of the Anthraquinone Series — 1-Mercapto-2-amino anthraquinone or salts of 1-mercapto-2 amino anthraquinone are condensed with 1-chloro-2-amino anthraquinone in the presence of condensing agents which effect condensation at the mercapto-group. Hydrogen sulphide is split off with formation of N-dihydro-1:2:2':1'-anthraquinoneazine, which latter also results when salts of 1-mercapto-2-amino anthraquinone are heated to a high temperature. (Ger. Pat. 357,767, which is an addition to German patent 336,922. E. Kopetchin.)

Fire-Extinguishing Compounds and Detergent Compounds — Chlorinated hydrocarbons are acted upon with water in Plauson colloid mills or similarly operating impact mills, eventually with addition of small amounts of protective colloids, such as albumens, glue, rubber latex, soaps, and of organic compounds capable of acting as solvents for the chlorohydrocarbons and water. The addition compounds act as dispersing agents. A mixture composed of 1 part of a chlorinated hydrocarbon and, for instance, 3 parts of water has the same fire-extinguishing effect as the pure chlorinated hydrocarbons, besides being distinguished from the latter by a smaller volatility. (Ger. Pat. 358,572. Plauson's Forschungsinstitut, Hamburg.)

Copper Sulphate From Scrap—Mill scrap or similar residues containing Cu as such or in form of alloys are roasted with chlorides, preferably NaCl (maximum 10 per cent), after the manner of the chloridizing roasting process as applied to sulphide ores, and subsequently treated with sulphuric acid. The Cu-containing scrap material is, prior to roasting, comminuted together with the sodium chloride. When tin-containing scrap is subjected to this process, small amounts of lime, SiO_2, Al_2O_3 or their salts are added to the material to be roasted. (Ger. Pat. 358,611. S. Hiller.)

Green Pigments—Nitroso-β-naphthol, preferably in form of its bisulphite compound, is acted upon with ferrous salts, preferably in the presence of turkey-red oil or similarly acting additions, with or without any of the mediums ordinarily used in the manufacture of lacquers. The formation of these mediums may also be caused to take place simultaneously with the production of the green pigment. Valuable pigments may also be obtained with a ferric salt provided the amount of the latter is less than theory requires. Ferric acetate gives valuable pigments even with the full theoretical amount of Fe. The green pigment is remarkably fast to light, water and alkalis, and is to be used in the production of inks for printing wall paper, books, or for lithographic work. (Ger. Pat. 356,973. Badische Anilin u. Soda Fabrik).

Condensation Products From Phenols and Aldehydes—To the reaction mixture a catalyst is added consisting of those phenols which, in addition to the OH-group or groups, contain any basic group or groups. The added catalyst, such as amino-phenols, methyl- and ethylaminophenols, aminonaphthols, hydroxyquinolines, hydroxydiphenylamines, particularly those aminophenols in which the H of the NH_2 or NH group is partly or entirely replaced by an alkyl-, aralkyl- or aryl-radicle, react with the aldehydes such as CH_2O or its polymers, furfuraldehyde, acrolein, in the same way as the phenols, so that they need not subsequently be removed from the final reaction product. For instance, from C_6H_5OH, CH_2O and p-aminophenol, or from C_6H_5OH, furfuraldehyde and p-aminophenol, homogeneous masses are obtained which are perfectly free from water and bubbles, insoluble and non-fusible, and are readily machined. They are particularly intended for electric insulating purposes. (Ger. Pat. 358,195. Felton-Guilleaume Carlswerk Actien Gesellschaft, Köln-Mühlheim.)

Resinous Condensation Products From Cresols and Xylenols The cresols or xylenols are treated with oxygen or air in the presence or absence of a catalyst. For instance, a current of moist air is passed for 10 to 12 hours through o-cresol heated to 150 to 170 deg. C. or through a phenol-containing crude cresol or m-xylenol, in the presence of a small amount of manganese dioxide or ferric chloride. The phenolic constitutents unacted upon are driven off with steam. The resulting resinous material constitutes, according to the duration of the oxidation treatment and the temperature, when air was used, a dark-brown to black mass which is soft, hard or brittle. Even those resins which are hard at the ordinary temperature may be melted by application of heat. By heating to higher temperatures the softer products are converted into highly lustrous, hard and brittle resins. The products are soluble in dilute NaOH, ether, alcohol, acetone and benzol, but practically insoluble in dilute Na_2CO_3 solution and in cold turpentine. The soft resins are also readily soluble in fatty oils, such as olive oil, whereas the hard resins go into solution only after heating or by prolonged action of the cold oil. The reaction presumably takes place in such a manner that at first the alkyl groups of the phenols are oxidized, and the resulting intermediate reaction products yield polymerization products either with each other or together or with unchanged phenols. (Ger. Pat. 357,756. Chemische Werke Grenznach Aktien-Gesellschaft.)

Washing and Bleaching Compound—Sodium peroxide and sodium bicarbonate are mixed together with soluble glass (sodium silicate) preferably in the presence of protective compounds. A 30 deg. Bé. water-glass solution is mixed with NaO_2, and the resulting mass is stirred with slightly more than equivalent amount of $NaHCO_3$ and the solidified mass is ground and dried. The protective compound to be added to the water-glass solution may be either magnesium or calcium silicate. (Ger. Pat. 357,956. Deutsche Gold und Silberscheideanstalt vorm. Roessler, Frankfurt.)

Liquid or Soluble Organic Compounds From Coal—A coal having a carbon content of not more than 85 per cent (referred to dry, ash-free substance) is subjected to hydrogenation by H_2 under high pressures and high temperatures. About 87 per cent of the coal used is thus converted into liquid or soluble form. No catalyst is used. The coal is subjected to pressure and heat in an atmosphere of hydrogen in the presence of a diluent liquid under the reaction conditions, the diluent used for the starting material to be hydrogenated consisting of high-boiling mineral oils or tar or high-boiling distillates or residues obtained therefrom. Due to the high-boiling diluent local overheating is excluded, and the reaction products are brought into solution. About 88 per cent of the coal is thus brought into a liquid or soluble form. (Ger. Pats. 299,783 and 303,272. Frederick Bergins.)

Conversion of Natural or Synthetic Varieties of Rubber Into Other Varieties of Rubber or Into Masses Resembling Gutta Percha—The hydrohalogen or halogen derivatives of certain kinds of rubber are reduced with metals (Zn) in a dispersive medium such as $CHCl_3$, $C_2H_4Cl_2$, and, if necessary, the resulting masses are washed with water or dilute acids. The resulting rubber has more or less viscous properties, according to the mode of preparation. When ethylene chloride is the dispersive medium, a substance resembling gutta percha is obtained. (Ger. Pat. 354,344. Siemens & Halske Aktien-Gesellschaft.)

Process for Protecting Fur and Wool From Moth and Other Insects—Animal fibers are protected from moth, etc., by treatment with the vapor of α-tetralon (α-tetrahydronaphthaleneketone) or mixtures of this with other suitable substances. The protective effect of α-tetralon is more lasting than that of chlorinated aromatic compounds, since it is less volatile. α-Tetralon is obtainable as an emulsion in soft soap or in the form of a powder, pellets or tables. Paper and fabrics may be treated with solutions of α-tetralon in petroleum spirit of high boiling point. (Ger. Pat. 357,063. Vereinigte Chemische Fabriken J. Norden & Co.)

Ammonium Sulphate From Crude Calcium Cyanamide—$CaCN_2$ is heated with $NaHSO_4$ and H_2O, the residue filtered off, and the liquor evaporated. The proportions of the reacting substances are so adjusted that the solution contains more than 1.3 parts (preferably 3 parts) of Na_2SO_4 to 1 part of $(NH_4)_2SO_4$; on evaporation the whole of the Na_2SO_4 crystallizes out, and by further evaporation of the mother liquor, technically pure ammonium sulphate is recovered direct. (Ger. Pat. 299,131, Bambach & Co.)

Code of Ethics Adopted for Engineers

Joint Committee of Engineering Societies Formulates Principles for Elevation of Dignity of Profession

Adoption of a code of ethics, governing its membership of approximately 20,000, is announced by the American Society of Mechanical Engineers. Ultimately, it is expected, this code, prepared by a joint committee of national engineering societies, will apply to the entire engineering profession, embracing more than 200,000 professional engineers.

The mechanical engineers are the first to adopt the code, according to the chairman of the joint committee, Prof. A. G. Christie of Johns Hopkins University. This action, Professor Christie stated, marks an advance in engineering ideals, and, in respect to the government of its members as a whole, places the profession in a position analogous to the professions of law and medicine.

The code commands loyalty to country, personal honor, fairness to contractors and workers and interest in the public welfare. Betrayal of professional confidences, undignified or misleading advertising and questionable professional associations and practices are prohibited.

Text of Code

The text of the code, as given out by John L. Harrington, president of the American Society of Mechanical Engineers, follows:

"Engineering work has become an increasingly important factor in the progress of civilization and in the welfare of the community. The engineering profession is held responsible for the planning, construction and operation of such work and is entitled to the position and authority which will enable it to discharge this responsibility and to render effective service to humanity.

"That the dignity of their chosen profession may be maintained, it is the duty of all engineers to conduct themselves according to the principles of the following code of ethics:

"1. The engineer will carry on his professional work in a spirit of fairness to employees and contractors, fidelity to clients and employers, loyalty to his country and devotion to high ideals of courtesy and personal honor.

"2. He will refrain from associating himself with or allowing the use of his name by an enterprise of questionable character.

"3. He will advertise only in a dignified manner, being careful to avoid misleading statements.

"4. He will regard as confidential any information obtained by him as to the business affairs and technical methods or processes of a client or employer.

"5. He will inform a client or employer of any business connections, interest or affiliations which might influence his judgment or impair the disinterested quality of his services.

"6. He will refrain from using any improper or questionable methods of soliciting professional work and will decline to pay or to accept commissions for securing such work.

"7. He will accept compensation, financial or otherwise, for a particular advice, from one source only, except with the full knowledge and consent of all interested parties.

"8. He will not use unfair means to win professional advancement or to injure the chances of another engineer to secure and hold employment.

"9. He will co-operate in upbuilding the engineering profession by exchanging general information and experience with his fellow engineers and students of engineering and also by contributing to work of engineering societies, schools of applied science and the technical press.

"10. He will interest himself in the public welfare, in behalf of which he will be ready to apply his special knowledge, skill and training for the use and benefit of mankind."

The joint committee which drew up the code was composed as follows:

American Society of Civil Engineers—C. C. Elwell, New Haven, Conn.; A. M. Hunt, New York.

American Institute of Mining and Metallurgical Engineers—J. Parke Channing and Philip W. Henry, New York.

American Society of Mechanical Engineers—Prof. A. G. Christie, Johns Hopkins University, Baltimore; H. J. Hinchey, Chicago; Charles T. Main, Boston; J. V. Martenis, Minneapolis; Robert Sibley, San Francisco.

American Institute of Electrical Engineers—Prof. Comfort A. Adams, Harvard University; C. Paccioli, Pittsfield, Mass.; George F. Sever, Toronto, Ont.; L. B. Stillwell, New York.

American Society of Heating and Ventilating Engineers—Frank T. Chapman and Perry West, New York; S. A. Jellett, Philadelphia.

Reclassification of Federal Employees Delayed

Although several hearings have been held by a sub-committee of the Senate Appropriations Committee, the final report on the bill to reclassify the employees of the federal government and readjust salaries has not been formed and in view of the heavy work devolving upon the Appropriations Committee because of the annual supply bills, fears are expressed that the reclassification measure will not be brought to action on the floor in time to assure passage at the present session of Congress. Senator Smoot, chairman of the sub-committee in charge of the bill, has stated, however, that a report may be expected shortly.

Friends of the reclassification bill are dubious of its passage in the present Congress, even if a report is forthcoming in January, because of the doubt over the shape in which the bill will appear when it emerges from committee.

Bill Has Had Stormy Career

The Civil Service Committee of the Senate considered this measure some weeks and reported it on Feb. 8 last with a recommendation that it be passed. Because of the financial features of the bill, it was referred to the Appropriations Committee for further study. The Civil Service Committee made a number of changes in the bill from the form in which it was passed by the House. While the sessions of the sub-committee on appropriations have been executive, with a number of government officials testifying as to their ideas, it is generally understood that further changes have been seriously considered by this committee. Senator Smoot himself is the author of another reclassification bill which originally projected reforms based upon a somewhat different theory than those contained in the Lehlbach-Sterling bill, which was the basis of the one now under consideration.

It is said that the Appropriations Committee has been considering further reductions in the number of classes outlined in the bill and that there has been serious thought of eliminating workers in the field and confining the measure to government employees within the District of Columbia. Changes in title and in relative pay for professional and sub-professional workers also have been suggested, it is said, because these men, especially technical workers, are leaving the service in increasing numbers.

Wisconsin Plans Colloid Studies Under Svedberg

Lecture Courses and Symposium Under Swedish Expert Expected to Attract Leaders in Field

The department of chemistry of the University of Wisconsin desires to call attention to the program for colloid chemistry which will be conducted by Prof. Thé Svedberg during the coming semester, commencing Feb. 1, 1923, and summer session, commencing June 25, 1923.

Prof. Thé Svedberg, of the University of Upsala, Sweden, will be in residence at the university from Feb 1 to Aug. 5. He will give two lectures a week on the general theory of colloids and will direct the experimental researches of a number of graduate students during the second semester. In the summer session the course of lectures given during the second semester will be repeated. Every necessary facility will be provided for the successful prosecution of researches. Those desiring to work under Professor Svedberg's personal direction, either during the second semester or during the summer session, should communicate promptly with Prof. J. H. Mathews, since only a limited number can be accommodated. The opportunity of hearing Professor Svedberg's lectures and doing work under his direction during the summer session will appeal to a great many professors and instructors at other educational institutions. A considerable number have already signified their intention of embracing this opportunity.

SEMINARY AND NATIONAL SYMPOSIUM PLANNED

Professor Svedberg will also conduct a seminary in colloid chemistry which will meet weekly during the second semester. The first half will be devoted to general theory and the second to biological applications of colloid chemistry. In the latter half of the work he will be assisted by Prof. Elmer Sevringhaus, of the department of physiological chemistry. Admission to the seminary will be open to chemistry students who have had a course in physical chemistry and who possess at least an elementary knowledge of the theory of colloids; and to advanced workers in the biological sciences.

From June 12 to 15, inclusive, a national symposium on colloid chemistry will be held at Madison to which all scientists interested in colloid chemistry are invited. A program of exceptionally interesting papers is now being formulated, and definite assurance of the attendance of nearly all of the most prominent American workers in the colloid field has already been given. About twenty papers will be presented by the authors in person and there will be ample time for thorough discussions. These discussions will be led by Professor Svedberg. More detailed information concerning the program of papers to be presented will appear in these columns later.

Fertilizer Manufacturers Confer With Agricultural College Officials

Representatives of fertilizer manufacturers conferred with officials of agricultural colleges and experiment stations from the New England states in Boston, Dec. 30. The officials explained the soil improvement needs of their states and what they are trying to accomplish for the benefit of agriculture. Policies and measures were pointed out, whereby fertilizer manufacturers and their salesmen may cooperate to better advantage.

The conference was called on the invitation of Prof. S B. Haskell, director of the Massachusetts State Experiment Station. Horace Bowker, vice-president of the American Agricultural Chemical Co., was selected as head of the fertilizer delegation, which included corporation officials, sales managers and field salesmen.

The meeting was in connection with the convention of the American Association for the Advancement of Science, which was held in Boston, Dec. 26 to 30. New England is one of the sections where high-analysis commercial fertilizers have been used to the exclusion of the poorer grades, owing to the nature of the principal crops raised there.

C.C.N.Y. Offers New Courses in Chemistry

The evening session of the College of the City of New York is offering, for the first time, courses in potable and industrial water and the chemistry of commerce in addition to the usual courses in chemistry.

Course 249—"Potable and Industrial Water"—deals with the special analytical work required for the analysis of water and with the interpretation of the findings of the analysis. Some attention is paid to water bacteriology. Prerequisite for this course is quantitative analysis and general bacteriology.

Course 269—"Chemistry of Commerce"—deals with the economics of the production and disposition of chemical products. It treats of the sources of raw materials and markets for the intermediate and finished product. The sources of energy and the conservation of waste by the utilization of byproducts is considered and the patent laws are discussed. Seminar work on the economic history of the development of various chemical industries is included. A knowledge of applied organic and inorganic chemistry is required for admission to this course.

Besides these courses, the regular courses in inorganic and organic chemistry, qualitative and quantitative analysis and electrochemistry will be given, all courses starting about Feb. 8, 1923.

Further information may be obtained from the director of the evening session, College of the City of New York, 189th St. and Convent Ave., New York City.

Customs Official and Coal-Tar Men Confer

Concentrate Efforts on Untangling Snarls in Chemical Schedule of New Tariff Law

Manufacturing interests were represented at a series of conferences on the proposed rules and regulations which if adopted will govern the entry of dyes under the new tariff law, held at the United States Appraiser's Stores in New York, last week.

Experts from the Bureau of Standards, the Treasury Department and the Tariff Commission conferred with importers and their representatives at the conferences. Tentative rules were drafted, and these are now being submitted to all parties interested before being forwarded to Washington for approval and adoption.

SNARL IN CRESOL DUTY

One of the problems with which the customs division of the Treasury Department is wrestling is an apparent conflict between the coal-tar products paragraph of the dutiable list of the new tariff act and the corresponding paragraph of the free list. Congress, in the "inclusive clause" of the dutiable paragraph, created two classifications, while only one is specified in the free list.

The specific case arose over imports of cresol, an intermediate used in a number of medicinal preparations and for some other purposes. This product is not mentioned by name in the tariff act, but falls within the inclusive clause.

In the paragraph placing a duty on intermediates, it is provided that: "All distillates of coal tar . . . which on being subjected to distillation yield on the portion distilling below 190 deg. C. a quantity of tar acids equal to or more than 5 per cent of the original distillate, or which, on being subjected to distillation, yield in the portion distilling below 215 deg. C. a quantity of tar acids equal to, or more than, 75 per cent of the original distillate," shall be dutiable There are two specifications in this classification, either one of which apparently would make the product dutiable.

PROPERTIES OF CRESOL OR SCHEDULE MUST BE MODIFIED

The free list paragraph, however, omits the 75 per cent below 215 deg. specification and provides that a product which does not yield 5 per cent or more of the original distillate below 190 deg. C. shall be admitted free. Cresol does not yield 5 per cent below 190 deg., but does yield 75 per cent below 215 deg. This fact would include it in the second specification of the dutiable list but inasmuch as this is omitted from the free list paragraph and below 5 per cent is to be admitted free, appraisers are at a loss as to how to proceed.

A number of other coal-tar products are said to be in a similar position. A decision is not expected in the case for several weeks

Opportunities for Research in Compiling Critical Tables

Board Encounters Gaps in Available Data Which Make Ideal Subjects for Theses and Research

In preparing for publication the data on physical properties of chemical substances, the editorial staff of International Critical Tables will find from time to time that important physical properties of substances of technical and scientific importance are missing from the literature. As fast as missing data of this character come to light, it is the policy to formulate research problems covering such missing data and to endeavor to interest chemists and physicists in undertaking the necessary investigations to supply the required data.

Most of the research problems formulated in this way will be suitable for bachelors' or masters' theses and in a few instances topics sufficiently broad to be suitable for doctors' theses will also be available. Many of them will be suitable for experimental problems in the ordinary laboratory courses in physical chemistry and physics. Thus, for example, the laboratory experiment covering the determination of solubility might to advantage deal with substances whose solubility is needed but is unknown. The average of the determinations made by a class of students, while not as accurate and reliable as the determinations made by a skilled investigator, will nevertheless be very valuable when they constitute the only data available on the subject. Moreover, the average student will be more interested in a laboratory experiment the results of which are of actual value and worthy of publication than he would be in repeating the measurement of a property of some system which has been measured many times before.

Problems Sought

International Critical Tables will be glad to submit to interested instructors in universities and colleges lists of problems of this character and to advise as far as it can concerning suitable apparatus and methods of measurement. It may be possible also in some instances to secure moderate financial assistance to aid in the purchase of materials and apparatus for investigators interested in carrying out work of this character. The results of such work may be published by the investigator in any appropriate publication medium and they should also be reported in duplicate to the office of International Critical Tables on completion of the work.

Problems Now Available

A number of problems on the following subjects are available at the present date: Heats of combination of solid oxides and iron compounds; specific heats of brass, solid oxides, steels, oils and fats, petroleum products, metals, salts, iron compounds, asphalts; latent heats of fusion of brass and metals; heat conductivity of steels; latent heats of vaporization of petroleum products; viscosities of industrial materials; rates of drying; hydrolysis of industrial materials; catalysis; transpiration of moisture; strength of industrial materials; thermal expansion of steels and iron compounds; freezing-point solubility diagrams of salts, acids, metals in water and soaps; boiling points of solutions; solubility of gases in molten metals and in water; chemical equilibrium; dissociation pressures at 1 600 deg. C.; electrical conductivity of metals and refractories; properties of colloidal systems; vapor pressures of metals and solutions; specific rotatory power of gliadin; index of refraction of solids; density of certain organic compounds and solutions; flash points and surface tensions of solutions.

Chicago Chemists Observe Pasteur Centennial

Life and Work of Great French Scientist Discussed From Many Angles at Meeting of Chicago Section

In commemoration of the Pasteur Centennial, the meeting of the Chicago section, American Chemical Society, held Dec. 15, was devoted to the life and work of the great French scientist. The address of the evening was delivered by Dr Edwin O. Jordan, head of the department of bacteriology and hygiene, University of Chicago. In a fascinating manner Dr. Jordan brought out the human side of Pasteur. Much of the work on the preparation of vaccines was carried out only through Pasteur's intense determination to seek scientific truth, for he was so extremely sensitive to suffering in others—whether animals or human beings—that he experienced mental and physical torture during the operations which were necessary for the studies. In view of this phase of his character, the violent attacks made upon him as an inhuman vivisectionist seem to us ridiculous and amusing.

Before the Biologic Group, Dr Morris Fishbein, associate in medical history, Rush Medical College, read a very interesting paper outlining the development of the Pasteur method of treating rabies—from the preliminary work on animals until the eventful day when the treatment was first applied to a human being. The result was successful and recognition of the value of the method was rapid. It is interesting to note that the treatment used today varies only in perhaps a few unimportant details from that developed by Pasteur.

Topics discussed before the other groups were: "Pasteur and His Work With Polarized Light," W. V. Evans, department of chemistry, Northwestern University; "Pasteur and the Fermentation Phase of the Baking Industry," George L. Teller, Columbus Laboratories; "Organic Mercury Compounds," Lyman Chalkley, Jr., Sprague Memorial Institute.

Development Work on Canadian Tar Sands

Further testing of Athabasca tar sands in the Canadian west on a practical scale is to be carried out during the winter at the laboratories of the University of Alberta in Edmonton, Alta. A report was recently submitted to the Advisory Scientific Research Council of Alberta by Dr. K. A. Clarke, who has been in charge of the experimental work of separating sand from bitumen for the past year or more, and the results therein announced were so encouraging and satisfactory that it was decided to continue along the lines already tried out and to make an actual test in road paving.

Bitumen Paving Material

With the sand brought from the McMurray district of Alberta, Dr. Clarke will apply the water-separation process of extracting the bitumen which he has developed, and will in this way obtain a stock of bitumen which will be available for future use as paving material. Other materials are exceptionally scarce in this district. Dr. Clarke has not had his process patented.

Dr. S. C. Ells of the federal department of mines, who is considered the premier authority in Canada on matters pertaining to the bitumen deposits and who has made a study of this mineral for the past 14 years in the West Indies, the United States, France and other portions of the European continent considers that commercial separation does not present greater difficulties than many other industrial problems which have already been solved satisfactorily. In 1913 Dr. Ells undertook the first systematic study of the McMurray deposits, regarding which at that time probably nothing of a definite nature was known. Since then every outcrop has been examined, accurate samples obtained and analyzed and topographical mapping of large areas completed. During the winter of 1915, in the face of serious difficulties, Dr Ells shipped to Edmonton the first large consignment of the McMurray sand. Subsequently the engineer assembled in Edmonton a small plant, and designed and laid the first pavements in which Canadian tar sands were used on a large scale. The signal success which marked this work demonstrated clearly the value of Alberta tar sands as a material for the surfacing of streets.

Water Separation Feasible

Subsequently realizing that large commercial development would depend upon the evolving of a satisfactory separation process, Dr. Ells spent months in considering the relative values of various separation and distillation methods. Owing to the war this work was not completed, but from the preliminary results obtained it appeared that the uses of heated water to which certain inexpensive reagents were added afforded the best chance of success.

Is Public Ready for Broad Scope in Technical Education?

President of Columbia Reports Signs of Tardy Recognition of Value of Fundamentals of Science and Humanities

President Nicholas Murray Butler of Columbia University, in his annual report to the trustees, says that opinion is moving in the direction of a policy of higher standards of admission and instruction in engineering schools. The time has come, in Dr. Butler's opinion, to give more special and concentrated attention to the advanced and research work of the university in the whole field of engineering.

"The line of separation between pure and applied science is increasingly difficult to discern and maintain," continues Dr. Butler. "The real distinction would appear to lie not so much in the subject matter as in the spirit with which the work of research is carried on.

"The applications in industry and in commerce of the principles and facts which constitute chemistry, physics and mechanics, for example, are made possible only by reason of a thorough understanding of those principles and facts. When research in the field of natural and experimental science was young in the United States, and when the dominant motive and interest of the people were largely material, it was perhaps not difficult to distinguish between what came to be called the field of pure science and that of applied science. Conditions have, however, sharply changed during the past generation, and the intermingling of the two is very considerable, even if it be not complete.

Place of Fundamentals in Curricula

"The policy of Columbia University in accepting 8 years ago the recommendation of the faculty of applied science to elevate the standard of admission to the Schools of Mines, Engineering and Chemistry, and to turn those schools definitely to the task of training leaders of the engineering profession and research workers, has resulted in greatly reducing the enrollment of students, and has left several departments of instruction overequipped for the work which they have to do, at least during the period when the new policy is establishing itself.

"There are signs that opinion is moving in the direction of the policy that was adopted 8 years ago. The dean of the faculty of applied science points out in his report that the importance attached here at Columbia to the humanities and to fundamental scientific studies as the basis of an advanced technical or professional training is increasingly recognized elsewhere.

Merit of Longer Courses

"A group of representatives of the most important engineering schools in the Middle Western states have unanimously approved a 5-year program of study for engineering students, with a view to giving the time gained to the study of the humanities and fundamental scientific subjects. Whether the program of engineering study be one of 5 years or 6 years is probably of less importance than its content and the possibility of the fundamental instruction being given by a large number of colleges and scientific schools, many of whose students would naturally transfer to Columbia to complete their engineering course.

"That there is ground for careful examination of all that relates to the program of study in the Schools of Mines, Engineering and Chemistry is obvious, and steps are taken to make that examination in the broadest way possible and with complete sympathy for the ideals which the university has set up."

Civil Service Openings

The United States Civil Service Commission announces open competitive examinations for laboratory assistant, junior grade and senior aid, and for junior chemist. The examinations will be held throughout the United States on Feb. 14 to fill vacancies in the Bureau of Standards, Department of Commerce, Washington, D. C. The entrance salary for laboratory assistant, junior grade, is $1,000 a year, plus the increase of $20 a month granted by Congress; for senior aid, $900 a year, for junior chemists $1,200 to $1,800, also plus the increase. The written examination consists of physics and chemistry, mathematics (through trigonometry) and mechanical drawing. The element of education and experience is weighted at 50 per cent.

The Bureau of Standards covers a wide field of work in physics, chemistry, engineering and industrial technology, and offers unparalleled opportunity for the study of a profession.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or secretary of the Board of U. S. Civil Service Examiners at the post office or custom house in any city.

Improved Service Arranged in Distribution of Fertilizer Statistics

The Bureau of the Census has agreed to the proposal of the National Fertilizer Association that the census of sulphuric acid and of acid phosphate be taken as of Jan. 1, rather than as of Nov. 30. The later date will permit the compilation of much more representative figures, it is contended. The association also pointed out the increased worth of the figures if there is no delay in making them public. In that connection the bureau is in a position, it was stated, to make the figures available forty-eight hours after the last return has been received. The fertilizer association is co-operating in an effort to obtain prompt answers to the questionnaire and a high percentage of responses.

Copper and Brass Research Association Summarizes First Year's Activity

In connection with the conclusion of the first full year of the Copper and Brass Research Association's activity as an unincorporated, voluntary organization of the brass and copper industries R. L. Agassiz, president of the Calumet & Hecla Mining Co., who is president of the association, said, at the meeting on Dec. 5:

"The research and educational work of the Copper and Brass Research Association has played an important part in the rapid growth of consumption of brass and copper during the past year—for, despite uncertain business conditions, copper consumption in this country is now substantially greater than in pre-war years. Having digested an unprecedented quantity of war-time scrap metal, the industry is now in a strong position.

"Our plan is to provide through the instrumentality of the Copper and Brass Research Association a technical and advisory service which may be freely called upon by users of our metals—a service which no one copper or brass producer or manufacturer could reasonably be expected to undertake alone.

Officers for the coming year were elected as follows: President, R. L. Agassiz; vice-presidents, C. F. Kelley, F. S. Chase, E. J. Rowland, Walter Douglas and U. T. Hungerford; treasurer, Stephen Birch; secretary, G. A. Sloan; and manager, William A. Willis.

Fertilizer Association Plans Annual Convention

With the idea of making its annual convention one of the features of next year's work, the National Fertilizer Association already is taking steps to that end. The executive committee of the association has fixed the time of the convention for the week of June 10. It will be held at White Sulphur Springs. Particular attention is to be given at this convention to the whole subject of cost accounting.

The executive committee at its meeting considered that portion of the report which the uniform cost-accounting committee has completed. At the same meeting John I. Tierney, the Washington representative of the association, reviewed the car and traffic situations.

Philadelphia Chemical Club Plans Course for Salesmen

The Philadelphia Chemical Club is perfecting plans for a course of instruction in chemistry for chemical salesmen, covering primarily a comprehensive series of lectures of practical value to men selling chemical products of various kinds. A committee was appointed to arrange for the proposed course, developing the important details and topics for lectures. Officers of the society elected for the coming year are: John H. Stutt, Jr., president; F. S. Havens, vice-president; W. H. Davis, secretary; and W. J. Thorne, treasurer.

Chemistry Fundamental to National Defense

Assistant Secretary of War Recognizes Importance of Industry to Welfare of Country in War or Peace

Assistant Secretary of War Wainwright, in a recent issue of the United States Army *Recruiting News*, recognizes the fundamental importance of the chemical industry to the national defense. This evidence of growing appreciation of the value of a highly developed chemical industry and chemical research is of special interest in view of Mr Wainwright's recent action in appointing an advisory board of chemical engineers from the industry.

"Being charged as I am by law with the responsibility of making adequate provision for the mobilization of material and industrial organizations essential to wartime needs," says Mr. Wainwright, "I have taken certain steps which may be interesting to describe briefly to you The War Department exists in time of peace largely for providing for the defense of the country in time of need. Therefore it is necessary in time of peace to make plans for war I am therefore giving a great deal of attention to planning how to utilize the commercial industries of the country to best advantage in time of war.

ALL WARFARE "CHEMICAL"

"As Assistant Secretary of War I am charged by law with the 'supervision of procurement of all military supplies and all other business of the War Department pertaining thereto and the assurance of adequate provision for the mobilization of material and industrial organizations to wartime needs' This responsibility makes the 'relations of the chemical industry to national defense' of paramount interest to me The requirements of the War Department in time of war for material produced directly or indirectly by the chemical industry of this country are stupendous in size and multitudinous in range

"There has been a popular use in the last few years of the term 'chemical warfare' as pertaining solely to the use of poison gases and other gaseous materials. Practically all modern warfare is 'chemical warfare.' Chemistry is just as seriously involved in high explosive ammunition, in shrapnel and in high explosive drop bombs as it is in poison gas. The manufacture of smokeless powder and high explosives, of which hundreds of millions of pounds are used in a year in modern warfare, are chemical processes involving chemically educated people, chemical facilities and chemical principles

IMPORTANCE IN MUNITIONS

"In fact, the most important contribution of chemical industry is its contribution toward the supply of munitions, and therefore I shall touch more fully upon that particular phase than any other. We have had it impressed upon us by the last war that munitions are the controlling factor in exerting a nation's maximum effort in combat. Man power can be mobilized and trained and placed in the field almost a year before the necessary munitions can be manufactured and supplied to them. Therefore, it becomes of paramount importance to the War Department to utilize every industry to assist in expediting munitions production."

New Denaturing Formula for Motor Fuel Alcohol

Approval of Gasoline as Denaturant Should Reduce Cost of Product to Compete With Gasoline

A new formula for the marketing of ethyl alcohol for use as a motor fuel has been approved by the prohibition unit of the Treasury Department Manufacturers of industrial alcohol believe it will reduce the cost of the blend to a point where it may be sold in competition with gasoline and thus enlarge the field of their product.

The formula is simple, being merely one part of gasoline, of specified grade, to 100 parts of alcohol, the gasoline rendering the blend unfit for human consumption Heretofore, the principal formula for industrial alcohol for use as a motor fuel has been 95 per cent alcohol blended with 5 per cent benzol, ether and alcohol.

The quantity of alcohol used as a motor fuel in the United States at present is small, but considerable was used during the war, although it is said that alcohol is used more than gasoline in Hawaii The new formula was evolved by an industrial alcohol manufacturer who foresees that the increasing consumption of gasoline is creating an inviting field for a competitive motor fuel.

The new formula, drawn by Dr J M Doran, head of the industrial alcohol division of the prohibition unit, and signed by D. H. Blair as commissioner of internal revenue, follows.

> The following formula, to be known as specially denatured alcohol Formula No 28-A, is hereby authorized for use in the manufacture of motor fuels
>
> For every 100 gal of ethyl alcohol of not less than 198 deg proof add 1 gal of gasoline of the quality specified below
>
> Volatility and distillation range When 5 per cent of the sample has been recovered in the graduated receiver, the thermometer shall not read more than [illegible] deg. C nor less than 50 deg C When 50 per cent has been recovered in the receiver, the thermometer shall not read more than 95 deg C
>
> The distillation test above outlined shall be made in the apparatus and in the manner described in Navy Department Specifications 7G1, dated Oct 2, 19[illegible], particularly referring to Grade A, fighting aviation gasoline

The blending must be at the point of manufacture.

Distribution of Fertilizer in Pennsylvania

The Bureau of Chemistry of the Department of Agriculture of the Commonwealth of Pennsylvania has issued a report showing a distribution of 325,000 tons of fertilizer and 275,000 tons of agricultural lime among the farmers of the state in 1921, with an approximate gross value of $12,000,000.

Paper Industries Show Scheduled for Spring

Grand Central Palace Will Be Scene of Newest Addition to Industrial Expositions

A new venture, of particular interest to the pulp and paper industry, is announced by the International Exposition Co., which will conduct a "Paper Industries Exposition" in the Grand Central Palace, New York, during the week of April 9, 1923. The executive committee of the American Paper and Pulp Association recently came to the conclusion that such a project would be well received by the industry and voted to support the undertaking. Accordingly, the International Exposition Co. is planning a "paper show" along the same lines as the chemical and other expositions, which have become institutions. The time was chosen so that the exposition would be held during the same week as the meeting of the American Paper and Pulp Association, the National Paper Trade Association and other associations of the paper industry.

The exposition will tell the complete story of paper, starting from the forest and the measures used to prevent waste, to encourage reforestration of cut-over lands to insure a supply of paper raw material for the future, the handling of the raw materials entering into paper, through the machinery with auxiliary apparatus and instruments with which the finished paper is made and the various products therefrom. Among the latter will be shown the newest products of the paper maker and converter

A committee has been organized for the exposition, comprising organized and unorganized groups of paper manufacturers, the trade publications, educational institutions, engineers and manufacturers of paper machinery. The committee comprises: Hugh P. Baker, secretary American Paper and Pulp Association; H. J. Berger, Editor *Paper Trade Journal*; Charles N. Bicknell, president National Paper Trade Association; F. D. Cowdery, Albany Felt Co.; Joseph L. Fearing, International Paper Co. of Chicago; Hardy S. Ferguson, paper mill engineer; E. B. Fritz, publisher of *Paper Industry*; Phil A. Howard, president American Paper Merchants; C. W. Hurtubis, Hammermill Paper Co.; Thomas J. Keenan, editor of *Paper*; Ralph H. McKee, Columbia University; John H. O'Connell, president American Pulp and Paper Mills Superintendents' Association; Frank W. Power, National Paper Trade Association; L. D. Post, publisher of *Paper Mill*; Walter J. Raybold, president American Paper and Pulp Association; George W. Sisson, Jr., Racquette River Paper Co.; E. C. Spear, Cheney Bigelow Wire Works; Tom Walden, editor of *U. S. Paper Maker*; George E. Williamson, president Technical Association, Pulp and Paper Industry; Louis E. Wise, N. Y. State College of Forestry; Fred W. Payne and Charles F. Roth, managers.

Calcium Arsenate Supply Adequate

Federal Inquiry Believed to Have Established Absence of Corner in Arsenic

Ample calcium arsenate will be available by the time it is needed for use in boll weevil control next summer. This is understood to be the finding of the representatives of the interested bureaus who made an intensive study of the situation in response to a Congressional resolution. The report probably will go to Congress before the end of January.

The shortage of calcium arsenate in 1922 resulted in the loss of cotton which could have been marketed for sums variously estimated from $5,000,000 to $100,000,000. As a result there is strong pressure on the federal bureaus concerned with the production, use and manufacture of arsenic and its compounds. An effort will be made to prevent a recurrence of such a shortage. The studies which have been made by the government's specialists indicate that unusual combinations of circumstances prevented a correct estimate of the 1922 demand for the poisons of which arsenic is the base.

SHORTAGE DUE TO SUPPLY AND DEMAND

There is no tendency to attach blame to the manufacturers of these products. There is no evidence that there was any conceived effort to advance prices. The fact that the 1921 demand for these materials was abnormally small left large stocks at the close of that year. With these stocks on hand, producers naturally did not enter into large output for 1922. Their failure to make contracts caused the price to slump to the point where it no longer was profitable for the smelters to refine their gray arsenic. The demand which wiped out the stocks came suddenly, with the result that production could not be brought quickly to the point necessary to supply the demand. It is believed that conclusions along these lines will be laid before Congress. It is probable that the prediction will be made that ample supplies of calcium arsenate, lead arsenate and paris green will be available to the cotton, fruit and truck growers, respectively, in time for their 1923 crops.

Countervailing Duties Fixed for Canadian Chemical Imports

The Treasury Department has declared countervailing duties on several chemicals when imported from Canada, to equalize the difference between the rates named in the new United States tariff and the corresponding duties imposed by the Canadian tariff on imports from this country. These rates are: calcium acetate, crude; calcium nitrate, cyanamide or lime nitrogen, 17½ per cent ad valorem, unless they are to be used as fertilizers, when they are entitled to entry at 10 per cent ad valorem.

U. S. Sulphur Producers Make Bid for Export Trade

That the sulphur producers of the United States intend to become even a greater factor in the world market is indicated by the formation of the Sulphur Export Corporation. The Union Sulphur Co., the Freeport Sulphur Co. and the Texas Gulf Sulphur Co. are members of the association, as are the following individuals: Henry Whiton, Clarence A. Snider, Eric P. Swenson, S. Magnus Swenson, Walter H. Aldridge and Wilbur Judson. Mr. Snider is president of the corporation, S. Magnus Swenson is vice-president, James T. Kilbreth secretary, and Charles W. Kemmler treasurer. All of the individuals mentioned reside in New York.

Sulphur to the extent of $30,000,000 was shipped from American mines in 1920. During that year the exports of sulphur were valued at $8,994,350.

Personal

Prof. E. C. BINGHAM, Lafayette College, has been elected chairman of the Lehigh Valley (Pa.) section of the American Chemical Society, Allentown. Dr. C. WITMER has been elected vice-chairman; Dr. A. BOGUE secretary and treasurer; and JOHN T. LITTLE councilor.

C. L. BRYDEN spoke on "Filters and Filtration" at the Gayley Chemical Laboratory of Lafayette College, Dec. 14.

W. D. COLLINS spoke before a joint meeting of Committee C 7 of the A.S.T.M. and Philadelphia section of the American Chemical Society on Nov. 17. His topic was "Hardness of Large Public Water Supplies in the United States."

CHARLES C. CONCANNON, acting chief, chemical division, Bureau of Foreign and Domestic Commerce, Washington, D. C., was in New York City conferring with representatives of the chemical industry during the week of Dec. 25.

Dr. EDWARD C. FRANKLIN, professor of organic chemistry of Leland Stanford Junior University, has been elected president of the American Chemical Society, succeeding Dr. Edgar F. Smith, of the University of Pennsylvania.

E. B. GERMAIN has been elected president of the Dunlop Tire & Rubber Corporation of America, with local plant on the River Road, Buffalo, N. Y.

Dr. ARTHUR A. HAMERSCHLAG has been elected president of the Research Corporation, vice Elon H. Hooker, resigned.

G. OENSLAGER, of the B. F. Goodrich Co., addressed the Cleveland section of the American Chemical Society, Dec. 27, on "The Rubber Plantation Industry in the Far East and the Preparation of Rubber."

CLARENCE W. POTTEIGER, of Reading, Pa., formerly city chemist and assistant engineer in the State Department of Health, engineering division, has been appointed secretary of the State Engineering Board, Harrisburg.

RICHARD PENFIELD, formerly chief engineer in the research department of The Barrett Co., has recently joined the engineering force of the Grasselli Chemical Co. at Cleveland.

[illegible]T, president of the Perth Amboy Tile Works, Inc., Perth Amboy, N. J., has been elected president of the local New Jersey Clay Miners' & Manufacturers' Association.

Prof. THE SVEDBERG, of the University of Upsala, will be in residence at the University of Wisconsin from Feb. 1 to Aug. 8, 1923. He will give a course of lectures on the general theory of colloids and will direct the experimental researches of graduate students.

GEORGE H. TABER, JR., has resigned as president of the Sinclair Crude Oil Purchasing Co., Philadelphia, Pa., to take active charge of the new oil refinery now in course of construction at Marcus Hook, Pa., for the parent organization, the Sinclair Refining Co.

JOHN MORRIS WEISS, until recently director of development of The Barrett Co., and CHARLES RAYMOND DOWNS, formerly chief chemist of The Barrett Co. and more recently engaged in special plant development work at the Buffalo plant of the National Aniline & Chemical Co., have formed a partnership as consulting chemists and chemical engineers under the name of Weiss & Downs. They have taken an office in the Chemists' Building, 50 East 41st St., New York City, and will shortly have laboratory facilities available there. Both of them are known for their inventions in the fields of coal-tar products, synthetic organic chemicals and catalysis. Recently they received an award of the Howard N. Potts gold medal from the Franklin Institute for the production of maleic acid by the catalytic oxidation of benzene.

Obituary

HERBERT H. HEWITT, founder and president of the Hewitt Rubber Co., Buffalo, N. Y., died at his home Dec. 19, aged 67 years.

FRED A. MARSH, general purchasing agent of the Link-Belt Co., died Dec. 11, at the age of 52, at his home in Chicago. Mr. Marsh was a member of the Link-Belt organization for over 38 years and was one of the organizers of the Purchasing Agents Association of Chicago, serving as its first president.

Business Conditions in 1922 and the New Year's Prospects

Volume of Production During the Past Year Has Been Satisfactory, Although Not Always Profitable. Outlook for 1923 Is for Greater Stability and Continued Activity

LOOKING BACK over 1922, the reviewer cannot help but be impressed by the substantial gains which have been made in the general business situation. Following the drastic deflation of 1920 and the subsequent depression, it was necessary for business to undergo many fundamental readjustments. And it was these changes that characterized 1921 and the early part of the year just passed. But as the stocks of raw materials and finished products which had piled up during 1921 began to disappear with the first approach of business revival, a very insistent demand for production was developed. At first affecting only the more basic industries, this demand gradually spread until it affected practically every line of business. Furthermore, since this manufacture was almost entirely for current consumption, it may well be expected that the increased productive activity will continue on into the new year.

The improvement during 1922 was made in the face of labor troubles of unprecedented severity, of a discouraging lack of favorable developments abroad and of a serious maladjustment of commodity prices that drastically curtailed the buying power of the country. With these obstacles largely removed, however, and a comparative stability attained both in production and distribution, the new year brings with it every prospect for further improvement both as regards volume of business and the margin of profit in its operation.

SOME COMPARISONS WITH 1921

Production of manufactured commodities in 1922 was about 50 per cent greater than in 1921, according to figures compiled by the Department of Commerce. Textile mills were about 20 per cent more active than in 1921, the iron and steel industry increased its output from 60 to 70 per cent over 1921, non-ferrous metals from 50 to 95 per cent, petroleum 15 per cent, coke 40 per cent, paper 20 to 30 per cent, rubber 40 per cent, automobiles 50 per cent, building construction 50 per cent, lumber 35 per cent, brick 50 per cent, cement 15 per cent, leather 20 per cent, sugar 45 per cent, and meats about 5 per cent. Agricultural receipts were in general higher than in 1921. The only declines of outstanding importance were 7 per cent in bituminous coal and 17 per cent in anthracite.

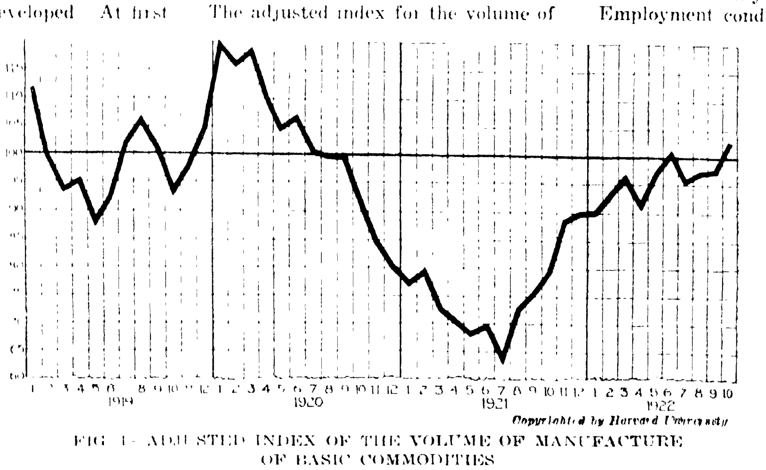

FIG. 1—ADJUSTED INDEX OF THE VOLUME OF MANUFACTURE OF BASIC COMMODITIES

The adjusted index for the volume of manufacture, which is compiled monthly by the Harvard Economic Service, stood at 99.7 for October, 1922, an increase of 6.3 over September and the highest point reached since September, 1920. This rise in the general index, it was pointed out, was due primarily to an increase among the industries producing basic commodities. Thus the Harvard index of basic commodities, which is shown in Fig. 1, rose from 97.3 in September to 102.8 in October, the highest figure reached since June, 1920. The prediction is made that further expansion is to be expected during the first half of 1923.

It is interesting to note that textiles and leather, two industries that are numbered among the largest consumers of chemicals, are now showing record activity. Thus for textiles the index was 117.6, the highest in nearly 3 years. The leather index was 106.8, coincident with the greatest activity since the middle of 1919. With the lower prices for hides and the relatively stable leather market, the tanner's margin of profit has been materially improved.

Employment conditions, perhaps better than any other factor, indicate the change in industry that has occurred since the beginning of 1922. The story in brief is a transformation from widespread unemployment to an acute labor shortage. The 3,233 establishments that report the volume of their employment to the Department of Labor are among 43 manufacturing industries and employ 1,556,537 persons. For each month since August there has been an increase over the preceding month. In November increases in the total number of employees were shown in 31 of the 43 industries. In the 42 establishments that produce chemicals there was a gain of 3.5 per cent in the number of employees and of 1.7 per cent in the amount of the payroll. Among other *Chem. & Met.* industries to show gains are the following: Glass 5.7 per cent in number and 8.6 per cent in amount, iron and steel 2.4 and 8.0 per cent, leather 2.8 and 3.8 per cent, pulp and paper 1.1 and 1.0 per cent and petroleum 3.4 and —5.2 per cent (a decrease).

Wholesale prices have made a gradual rise in 1922 and the index number of the Department of Labor is over 10

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	**171.30**
Last week	168.35
January, 1922	141
January, 1921	181
January, 1920	242
April, 1918 (high)	286
April, 1921 (low)	110

The sharp advance in this week's index number is attributable chiefly to the rise in the price of cottonseed oil and bleaching powder—two of the most important commodities on the list. Slightly lower prices were noted for glycerine and citric acid.

per cent greater than a year ago. Farm products and metals had the greatest relative gains. The index numbers of *Dun's* and *Bradstreet's* showed larger increases during the year, the former rising 13 per cent and the latter 21 per cent.

An increase during November from 154 to 156 in the "all commodities" index of the Bureau of Labor Statistics brings this figure to the highest level since February, 1921, as will be noted in the accompanying chart (Fig. 2). This price curve has shown a tendency to flatten out in recent months and it is this apparent stability that has most favorably affected business.

Chemical Prices

Chemical prices, on the other hand, have followed a somewhat less regular course. After paralleling the general curve in its precipitous drop during the first 5 months of 1921, the *Chem & Met.* weighted index of chemical prices showed a reaction to fairly high levels until October. Another slump, however, which reached its low point in February, 1922, brought the index number down almost to the previous low point in May, 1921.

From January until June of the present year there was a rapid improvement, but this was directly followed by a decline during the summer months of over 10 points. The greater industrial activity that began in October and to some extent the passage of the new tariff on Sept. 21 have been largely responsible for the sharp advances that have resulted in an increase of 17 points since Oct. 1. The trend is clearly shown in Fig. 2, in which chemical prices are compared with those of all commodities.

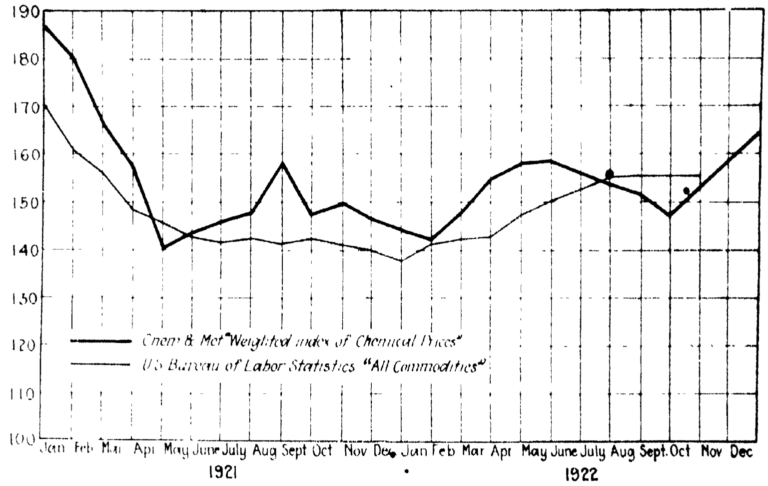

FIG. 2—THE TREND OF WHOLESALE PRICES IN 1921 AND 1922

The Chemical and Allied Markets in 1922

Higher Prices and a More Stable Market Are the Features of a Review of the Year's Activity Among the Sellers of Chemicals and Related Materials

At the close of 1922 the entire chemical list, with the exception of a few commodities of minor importance, were at much higher levels than at the beginning of the year. Although business in general was not up to the expectations of most of the producers, the market was more stabilized and prices throughout were well sustained.

The most important features of the year were the sharp advance of all wood chemicals and solvents and the rise in insecticide prices. Methanol, quoted at 61c. per gal. in January, was advanced to \$1.23 in December. This advance affected all acetates and most of the solvents. Calcium acetate advanced from \$1.75 per 100 lb. to \$3.50. Formaldehyde, quoted at 10½c. in January, was steadily advanced to 16c. per lb. in December. Fusel oil showed a gain of \$1 per gal. for the year. Prices opened at \$2.50 and closed at \$3.50 per gal. Amyl acetate was also advanced from \$2 per gal. to \$2.80. Glacial acetic acid showed a gain of 3c. per lb. for the year. All other grades were advanced on the same basis.

Arsenic was the most outstanding single commodity of the entire list. Prices showed very little change during the first 6 months, but September importations were unusually small and the demand from the agricultural industry increased considerably. Domestic producers tried hard to keep prices within the reach of consumers, but speculative interests advanced quotations to 16c. per lb. There seems to be very little relief in sight and higher prices are quite probable for 1923. Lead arsenate was advanced in sympathy with the arsenic scarcity and prices showed a gain of 8c. per lb. January figures were around 15c. per lb. They declined to 13c. in July and closed the year at 21c. per lb. Prussiates showed a strong tendency, especially in the potash group. Yellow prussiate of potash was quoted at 24c. in January and continually advanced to 38c. per lb. Red prussiate opened the year at 30c. per lb. and rose to 92c. per lb. at the close.

The alkali market for export was a complete disappointment to producers. The only relief was the very active demand for domestic consumption. Alkali prices showed little variance for the year, with January figures at \$3.25 per 100 lb. and December prices at \$3.50 for caustic soda. Soda ash held at \$1.75 per 100 lb. throughout. Bleaching powder became quite active during the past 2 months and producers reported a heavily sold up market at the works. Prices are due for a rise early in 1923, in view of the strong demand and the pronounced scarcity.

Contract Prices for Bleach are Advanced by the Principal Producers

Holidays and Inventory Period, However, Are Responsible for a General Lack of Buying Interest in the New York Chemical Market

THE chemical market in New York City during the past week has been quite inactive, due to the intervening holidays and the inventory period. Producers of bleaching powder, however, announced an advance for contracts and future shipments and reported a well sold up condition at the works. Second hands have not shown an eager desire to dispose of any stocks and buyers have found some difficulty in locating round quantities. Manufacturers of alkalis and heavy acids reported a satisfactory volume of contract business for 1923 and were quite optimistic regarding business conditions for the new year. Arsenic still remains the bright spot of the market, with spot supplies practically extinct. Formaldehyde prices are being well sustained at recent levels. Prussiates have shown a tendency to ease off and both the potash and soda were fractionally lower. Barium chloride, caustic potash, permanganate of potash and copper sulphate were somewhat firmer at slightly higher levels.

HIGH SPOTS OF THE MARKET

Arsenic—Spot transactions were quite scarce due to the limited stocks. Futures were quoted at 15@15½c. per lb. January delivery. The general range, however, was around 16@16½c. per lb.

Bleaching Powder—Producers announced an increase due to the strong demand and scarcity of stocks. Prices range around \$2 per 100 lb., f.o.b. works, large drums, for futures and contracts. Spot quotations were heard at \$2.25 per 100 lb., in large drums.

Copper Sulphate—Producers have advanced quotations ¼c. per lb. for large crystals, due to the heavy demand for agricultural and export purposes. Quotations range around \$6@\$6.25 per 100 lb.

Caustic Soda—Buying has slackened considerably for spot requirements and the only business consummated is for contract over 1923. Producers quote futures at \$2.50 per 100 lb., basis 60 per cent, f.o.b. works, carload lots. Export quotations range around \$3.50@\$3.60 per 100 lb. standard brand.

Formaldehyde—Resale stocks have greatly diminished and the best price heard on spot was 16c. per lb. Producers quote carload lots at 16c. per lb. and lesser quantities at 16½c. The demand continues quite active.

Prussiate of Soda—Demand has eased off considerably and prices were quoted down to 19c. per lb. on spot. Some stressed lots were heard as low as 18½c.

COMPARISON OF THE AVERAGE MONTHLY PRICES IN THE NEW YORK MARKET FOR 35 IMPORTANT COAL-TAR PRODUCTS

Coal-Tar Products and Vegetable Oils in 1922

The coal-tar products market has shown practically the same features as the chemical market. All basic commodities, such as benzol, cresylic acid, phenol and toluol, have shown exceptional strength and materially affected the otherwise quiet intermediate market. Although producers of crudes have not advanced prices to any noticeable extent, a pronounced scarcity has existed throughout the year at the works and second hands have demanded a premium on any spot material. Cresylic acid is quoted at 60c. per gal. for future delivery. Resale material, on the other hand, has brought as high as $1 per lb. Aniline oil and beta naphthol have completely recovered from their recent slump and producers have reported a satisfactory volume of business during the past 2 months. Phenol was quoted at 12c. per lb. during the early part of the year and steadily advanced to 34c. per lb at the close. Producers reported a completely sold up market at the works since August and very little relief seems to be in sight for the early part of 1923

Conditions in the market during the last quarter seemed quite satisfactory to leading dealers. Prices for most commodities were at higher levels at the close of the year than at any time during 1922 Cottonseed oil was quoted at 7c. per lb in January and advanced to 9c. per lb in December All indications point to a higher market for 1923 Linseed oil recorded a gain of 20c per gal. for the year. Prices early in the year were quoted at 70c. per gal and gradually advanced to 90c

---

The Other Side of the Ledger

In a recent editorial in the *Nation's Business* it has been pointed out that even in the boom year of 1920 not all corporative enterprises were successful. In fact, a large proportion of them showed no net income at all, according to the income tax statistics which have just been published by the Treasury Department. Ten thousand firms were "in the red." Of the corporations producing chemical and allied products, 47 per cent showed no income. This proportion was exceeded by only two industries—namely, mining and quarrying, with 60 per cent, and rubber and rubber goods with 58 per cent.

The proportion of corporations showing no net income for the year 1920 follows:

Industry	Per Cent
Mining and quarrying	60
Rubber and rubber goods	58
Chemical and allied products	47
Textiles and products	45
Food products, liquor and tobacco	45
Leather and products	43
Transportation and other public-utilities	37
Trade	34
Metal and metal products	33
Public service, professional amusements, hotels, etc	32
Finance, banking and insurance	30
Construction	30
Stone, clay and glass	37
Lumber and wood products	27
Printing and publishing	21
Paper, pulp and products	20

Steel Market Ends Year in Good Condition

Price Situation Better Than Was Expected a Few Months Ago—Mills Sustaining Production

PITTSBURGH, Dec. 29, 1922.

While it would be extravagant to say that the steel market is ending the year in a blaze of glory, it is ending it much better than was expected. An outstanding feature of the general condition, indeed, is that a rather large volume of business is being put through with a minimum of excitement. Orders are placed smoothly and easily, one mill or another being able to arrange the delivery desired provided the buyer is willing to pay the full market price The business that fails to go through is the business the buyer expects to place at a price concession. The market presents a strong contrast with that of the summer and early autumn in that excitement is lacking, but the volume of tonnage is not to be judged by such appearances The mills are quietly filling up. Some will soon be completely filled for first quarter, while others, which 2 months ago seemed likely to be unable to maintain production even to the end of the year, are now in comfortable position and with several weeks of full operation already assured

The market is in much better condition than was expected a month or two months ago It is more or less customary for buyers to ask mills to discontinue or decrease shipments in December, to lighten the work of inventory taking, but no such disposition has been exhibited this year. Only in very occasional instances have mills decreased production in the past month, although there are some cases of departments being closed for repairs.

PRICE SITUATION STRONG

The price situation is correspondingly strong and is better than was expected. Bars, shapes and plates were expected by many observers to be lower by this time, even 1.75c. having been mentioned a couple of months ago as a possibility. Instead, the regular 2c. price is more strictly observed than was the case in November. The market may indeed be described as firm at that level. Some large consumers have been expecting a concession on their first quarter requirements, but have been offered nothing outside of the regular price, and it is now hinted they may not receive full supplies if they delay further in placing their commitments.

In the sheet market the reports current 3 weeks ago of two or three mills making slight concessions from the regular price have disappeared. The market seems to be very firm on the basis of 3.35c., for common black, with galvanized at 4.35c. and blue annealed at 2.50c. The announcement of the Brier Hill Steel Co. of an advance in its price from 3.35c. to 3.50c. is now, however, taken seriously by other sellers. Incidentally, arrangements have been practically concluded whereby the Youngstown Sheet & Tube Co. will absorb this interest. Special finish sheets have been in particular demand, and of all the sheet mills, those that make special finish sheet mills have the larger order books. According to delivery and other conditions automobile sheets are bringing 4.70c., 4.85c. and 5c.

Tin plate is moving in a moderate way, with little contracting for the half year but with heavy buying in specific orders for the early months. The regular price of $4.75 is being generally observed. Many independent producers had expected the Steel Corporation to make an advance in naming its prices for the new period. Predictions in the trade are that domestic consumption in 1923 will be very large, stocks of canned goods being quite moderate. On the whole, domestic consumption in the past year was probably well ahead of that in any previous year. Production was about 1,400,000 gross tons, against 1,512,000 tons in the record year, 1917, but exports were much lighter.

Demand for tubular goods continues heavy. The open weather has helped building operations as well as work in the oil fields. The National Tube Co. has most of its finishing departments closed this week for necessary repairs, but is maintaining steel production as far as possible. It has just purchased 10,000 tons of bessemer billets from a Pittsburgh independent at $36.50 Pittsburgh, the regular market, to supplement its regular supplies in making butt weld pipe

Demand for wire products continues heavy, with some producers sold as far ahead as they usually care to sell. Prices are firm on the basis of 2.45c. for plain wire and $2.70 for nails.

COKE AND PIG IRON

Foundry pig iron at valley furnace has advanced another dollar a ton, being firm now at $27 furnace, while the first quarter buying movement, early in December, was at $25. There was more iron bought on that movement than furnaces expected to sell when they made the price offer. All producers of foundry iron seem to be in comfortable position as to sales, while some are probably not in comfortable position as to coke supplies, since the advancing market of the past fortnight, due to purchasers for domestic consumption, has produced prices quite out of line with pig iron prices. Basic iron has not responded to the general stiffening tendency to any great extent, probably because there are several steel works willing to sell iron, but the market seems to be at about $25 valley, which compares with a few sales made recently at about $24.25. Bessemer is quiet at $27.50.

Buying of Connellsville coke by Eastern distributers for domestic use has been lighter in the past week, simply because there is no longer much coke to be picked up. Some domestic demand from the West has developed this week. The market is quotable at $9@$9.50, rather irrespective of grade, an advance of $2.50 to $3, from the recent minimum.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Caustic soda, 76%, solid, drums, f.a.s.	100 lb.	3 50 –	3 75
Caustic soda, 76%, solid, drums, contract	100 lb.	3 35 –	3 40
Caustic soda, basis 60%, wks., contract	100 lb.	$2.50 –	$2 60
Caustic soda, ground and flake, contracts	100 lb.	3 80 –	3 90
Caustic soda, ground and flake, resale	100 lb	$4 00 –	$4 15
Sodium acetate, works, bags	lb	07½ –	07¾
Sodium bicarbonate, barrels	100 lb.	1 75 –	1 85
Sodium bichromate, casks	lb	07½ –	07¾
Sodium bisulphate (niter cake)	ton	6 00 –	7 00
Sodium bisulphite, powd., U.S.P., barrels	lb	04¼ –	04½
Sodium chlorate, kegs	lb	06 –	07
Sodium chloride	long ton	12.00 –	13 00
Sodium cyanide, cases	lb.	19½ –	23
Sodium fluoride, barrels	lb	09 –	09½
Sodium hyposulphite, barrels	lb	03 –	.03½
Sodium nitrite, casks	lb	08¼ –	09
Sodium peroxide, powd., cases	lb	.28 –	30
Sodium phosphate, dibasic, barrels	lb.	.03¼ –	.04
Sodium prussiate, yellow drums	lb.	.19 –	20
Sodium silicate (40 deg. drums)	100 lb	1.25 –	1 30
Sodium silicate (60 deg. drums)	100 lb	2 25 –	2 40
Sodium sulphide, fused, 60-62%, drums	lb	04½ –	04¾
Sodium sulphite, crys., barrels	lb.	03½ –	03¾
Strontium nitrate, powd., barrels	lb	09½ –	10
Sulphur chloride, yellow drums	lb	04½ –	05
Sulphur, crude	ton	18 00 –	20 00
Sulphur dioxide, liquid, cyl.	lb	08 –	08½
Sulphur, flour, barrels	100 lb	2 50 –	3 15
Sulphur, roll, barrels	100 lb.	2 15 –	2 20
Talc—imported, bags	ton	30 00 –	40.00
Talc—domestic powd., bags	ton	18 00	25 00
Tin bichloride, barrels	lb	10½ –	10¾
Tin oxide, barrel	lb	45 –	47
Zinc carbonate, bags	lb	14 –	14½
Zinc chloride, gran., barrels	lb	07 –	07½
Zinc cyanide, drums	lb	42 –	44
Zinc oxide, XX, barrels	lb	07½ –	08
Zinc sulphate, barrels	100 lb.	2 75 –	3 00

Coal-Tar Products

Alpha-naphthol, crude, barrels	lb	0 95 –	1.00
Alpha-naphthol, ref., barrels	lb	1 05 –	1.10
Alpha-naphthylamine, bbl	lb.	.28 –	.30
Aniline oil, drums	lb	16½ –	.17
Aniline salts, barrels	lb	24 –	25
Anthracene, 80%, drums	lb.	75 –	1.00
Anthracene, 80%, imp. drums, duty paid	lb.	.65 –	.70
Anthraquinone, 25%, paste, drums	lb	.70 –	.75
Benzaldehyde, U.S.P., carboys	lb	1.35 –	1 40
Benzene, pure, water-white, drums	gal	30 –	35
Benzene, 90%, drums	gal	28 –	32
Benzene, 90%, drums, resale	gal	37 –	40
Benzidine base, barrels	lb	.85 –	90
Benzidine sulphate, barrels	lb	75 –	80
Benzoic acid, U.S.P., kegs	lb.	70 –	.75
Benzoate of soda, U.S.P., barrels	lb.	57 –	.65
Benzyl chloride, 95-97%, ref., drums	lb	25 –	.27
Benzyl chloride, tech., drums	lb	.20 –	.23
Beta-naphthol, sublimed, barrels	lb	.55 –	.60
Beta-naphthol, tech., barrels	lb	.25 –	.26
Beta-naphthylamine, tech.	lb	1 00 –	1.25
Carbazol, barrels	lb	.75 –	.90
Cresol, U.S.P., drums	lb	14 –	.20
Ortho-cresol, drums	lb.	18 –	.22
Cresylic acid, 97-99%, drums	gal.	60 –	.65
Cresylic acid, 95-97%, drums	gal.	.55 –	.58
Cresylic acid, 97%, resale, drums	gal.	1.00 –	1.05
Dichlorbenzene, drums	lb.	07 –	.09
Diethylaniline, drums	lb.	.50 –	.60
Dimethylaniline, drums	lb.	.39 –	.41
Dinitrobenzene, barrels	lb.	.20 –	.22
Dinitroclorbenzene, barrels	lb.	.22 –	.23
Dinitronaphthalene, barrels	lb.	.3	.32

Dinitrophenol, barrels	lb.	$ 34 -	$ 36
Dinitrotoluene, barrels	lb	22 -	.24
Dip oil, 25%, drums	gal	25 -	.30
Diphenylamine, barrels	lb	54 -	56
H-acid, barrels	lb.	.75 -	.80
Meta-phenylenediamine, barrels	lb.	95 -	1 00
Michler's ketone, barrels	lb	3 75 -	3 85
Monochlorbenzene, drums	lb	08 -	10
Monoethylaniline, drums	lb	95 -	1 10
Naphthalene crushed, barrels	lb	05½-	06
Naphthalene, flake, barrels	lb	06 -	06½
Naphthalene, balls, barrels	lb	06½-	07
Naphthionate of soda, barrels	lb.	.58 -	.65
Naphthionic acid, crude, barrels	lb	60 -	65
Nitrobenzene, drums	lb	10 -	12
Nitro-naphthalene, barrels	lb	30 -	35
Nitro-toluene, drums	lb	15 -	17
N-W acid, barrels	lb.	1 20 -	1 30
Ortho-amidophenol, kegs	lb	2 25 -	2 30
Ortho-dichlor-benzene, drums	lb	17 -	20
Ortho-nitro-phenol, barrels	lb	85 -	90
Ortho-nitro-toluene, drums	lb	12½	14
Ortho-toluidine, barrels	lb	14 -	16
Para-amidophenol, base, kegs	lb	1 15 -	1 20
Para-amidophenol, HCl, kegs	lb	1 20 -	1 25
Para-dichlorbenzene, barrels	lb	17 -	20
Paranitroaniline, barrels	lb	75 -	80
Para-nitrotoluene, barrels	lb	55 -	65
Para phenylenediamine, barrels	lb	1 50 -	1 55
Para-toluidine, barrels	lb	85 -	90
Phthalic anhydride, barrels	lb	40 -	50
Phenol, U S P, drums	lb	34 -	35
Picric acid, barrels	lb	20 -	22
Pyridine, domestic, drums	gal	1 60 -	1 75
Pyridine, imported, drums	gal	1 40 -	1 60
Resorcinol tech, kegs	lb	1 50 -	1 55
Resorcinol pure, kegs	lb	2 00 -	2 10
R-salt, barrels	lb	55 -	60
Salicylic acid, tech, barrels	lb	35 -	37
Salicylic acid, U S P, barrels	lb	.40 -	42
Solvent naphtha, water white, drums	gal.	37 -	40
Solvent naphtha, crude, drums	gal	22 -	24
Sulphanilic acid crude, barrels	lb	20 -	22
Thiocarbanilide, kegs	lb	35 -	38
Toluidine kegs	lb	1 20 -	1 30
Toluidine mixed, kegs	lb	30 -	35
Toluene, tank cars	gal	35 -	37
Toluene drums	gal	40 -	43
Xylidine drums	lb	40 -	45
Xylene pure, drums	gal	45 -	50
Xylene pure tanks	gal	45 -	
Xylene, com, drums	gal	40 -	42
Xylene com, tanks	gal	30 -	

Naval Stores

Rosin B-D, barrel	280 lb	$6 10	
Rosin E-I, barrel	280 lb	6 20 -	
Rosin K-N, barrels	280 lb	6 30	$6 85
Rosin W G W W, barrels	280 lb	7 75 -	8 25
Wood rosin, barrels	280 lb	6 25	
Spirits of turpentine, barrels	gal	1 36 -	1 37
Wood turpentine, steam dist, barrels	gal	1 35 -	
Wood turpentine, dest dist, barrels	gal	1 25 -	
Pine tar pitch, barrels	200 lb	-	6 00
Tar, kiln burned, barrels (500 lb)	bbl	-	12 50
Retort tar, barrels	500 lb	-	11 00
Rosin oil, first run, barrels	gal	43 -	
Rosin oil, second run, barrels	gal	51 -	
Rosin oil, third run, barrels	gal	53 -	
Pine oil, steam dist	gal	-	90
Pine oil pure dest dist	gal	-	85
Pine tar oil, ref	gal	-	46
Pine tar oil crude, tank f o b Jacksonville, Fla	gal	-	35
Pine tar oil, double ref, barrels	gal	-	75
Pine tar, ref, thin barrels	gal	-	.25
Pinewood creosote, ref, barrels	gal	-	.52

Vegetable Oils

Castor oil, No 3, barrels	lb.	$0 12 -	$0 12½
Castor oil, AA, barrels	lb	12½-	13
China wood oil, barrels	lb.	.12½	.12¾
Coconut oil, Ceylon grade, barrels	lb.	08½-	.08¾
Coconut oil, Cochin grade, barrels	lb.	.09 -	09¼
Corn oil, crude, barrels	lb.	.10½-	.10¾
Cottonseed oil, crude (f o b. mill), tanks	lb.	.09 -	
Cottonseed oil, summer yellow, barrels	lb.	.10½-	11
Cottonseed oil, winter yellow, barrels	lb.	.11 -	.11½
Linseed oil, raw, car lots (domestic), barrels	gal.	.90 -	.91
Linseed oil, raw, tank cars (domestic)	gal.	.86 -	87
Linseed oil, boiled, 5-barrel lots (domestic)	gal.	92 -	.93
Olive oil, denatured, barrels	gal.	1 05 -	1 12
Palm, Lagos, casks	lb.	.07½-	.07¾
Palm kernel, barrels	lb.	.08 -	.08½
Peanut oil, crude, tanks (f.o.b. mill)	lb.	.12 -	.12½
Peanut oil, refined, barrels	lb.	.13½-	.14
Rapeseed oil, refined, barrels	gal.	.79 -	.80
Rapeseed oil, blown, barrels	gal	$ 86	$ 87
Soya bean oil (Manchurian), barrels	lb	11½-	
Soya bean oil, tank, f o b, Pacific coast	lb	09½-	09¾

Fish Oils

Light pressed menhaden, barrels	gal	$0 60 -	.
White bleached menhaden, barrels	gal	64 -	65
Blown menhaden, barrels	gal	.68 -	.69
Whale Oil No 1 crude, tanks, coast	lb	06 -	06½

Dye & Tanning Materials

Divi-divi, bags	ton	$38 00	$39 00
Fustic, sticks	ton	30 00	35 00
Fustic, chips, bags	lb	04 -	05
Logwood, sticks	ton	28 00 -	30 00
Logwood chips, bags	lb	02½ -	03½
Sumac, leaves, Sicily, bags	ton	65 00	
Sumac, ground, bags	ton	55 00	60 00
Sumac, domestic, bags	ton	35 00 -	
Tapioca flour, bags	lb	03¾ -	05

EXTRACTS

Archil, conc, barrels	lb	$0 18 -	$0 20
Chestnut, 25%, tannin tanks	lb	02 -	03
Divi-divi, 25%, tannin, barrels	lb	04 -	05
Fustic, crystals, barrels	lb	20 -	22
Fustic, liquid, 42 deg, barrels	lb	08 -	09
Gambier liquid, 25%, tannin barrels	lb	08 -	.09
Hematine crystals, barrels	lb	14 -	18
Hemlock, 25%, tannin, barrels	lb	04 -	05
Hypernic solid, drums	lb.	.24 -	.26
Hypernic, liquid, 51 deg, barrels	lb	14 -	17
Logwood, crystals, barrels	lb	.19 -	.20
Logwood, liquid, 51 deg barrels	lb	09 -	10
Quebracho solid, 65%, tannin, barrels	lb	04¼-	.05
Sumac, domestic, 51 deg, barrels	lb	06½-	.07

Waxes

Bayberry, barrels	lb	$0 28 -	$0 30
Beeswax, refined, dark, bags	lb	30 -	32
Beeswax, refined, light, bags	lb	34 -	35
Beeswax pure white, cases	lb	39 -	40
Candelilla, bags	lb	34 -	35
Carnauba No 1, bags	lb	39 -	40
Carnauba No 2 North Country bags	lb	23 -	24
Carnauba, No 3 North Country, bags	lb	17½-	18
Japan, cases	lb	15 -	15½
Montan, crude, bags	lb.	03½-	04
Paraffine, crude, match, 105-110 m p	lb.	.04 -	04¼
Paraffine, crude, scale 124-126 m p, bags	lb.	02½-	02¾
Paraffine ref, 118-120 m p, bags	lb	.03½-	.03½
Paraffine, ref, 125 m p bags	lb.	.03¾-	03½
Paraffine, ref, 128-130 m p, bags	lb.	.04 -	.04¼
Paraffine, ref, 133-135 m p, bags	lb.	.04½-	04¾
Paraffine, ref, 135-137 m p, bags	lb	05 -	05¼
Stearic acid, single pressed, bags	lb	.10 -	10¼
Stearic acid, double pressed, bags	lb	10½-	10¾
Stearic acid, triple pressed, bags	lb	11 -	.11½

Fertilizers

Ammonium sulphate, bulk, f o b works	100 lb	$3 20 -	$3 25
Ammonium sulphate, f a s, N Y, double bags	100 lb	3 65 -	3.75
Blood, dried, f o b, N Y, bulk	unit	4 60 -	.
Bone, 3 and 50, ground, raw, bulk	ton	30 00 -	35 00
Fish scrap, dom, dried, f o b works	unit	5 00 -	5 10
Nitrate of soda, bags	100 lb	2 57½-	2 60
Tankage, high grade, f o b Chicago	unit	4 60 -	4 65
Phosphate rock, f o b mines, Florida pebble, 68-72%	ton	3 50 -	4 00
Tennessee, 78-80%	ton	7 00 -	8 00
Potassium muriate, 80%, bags	ton	35 55 -	38 25
Potassium sulphate, bags	unit	1 00 -	. . .

Crude Rubber

Para—Upriver fine	lb.	$0 25½-	.25¾
Upriver coarse	lb	17½-	.17¾
Upriver caucho ball	lb.	.20½-	.20¾
Plantation—First latex crepe	lb.	.27½-	.27¾
Ribbed smoked sheets	lb.	.27½-	.27¾
Brown crepe, thin, clean	lb	.23 -	.23½
Amber crepe No. 1	lb.	.23 -	.23½

Miscellaneous Materials

Asbestos, crude No 1 f o b, Quebec	short ton	$650 00	$700 00
Asbestos, shingle, f o b, Quebec	short ton	60.00 -	80 00
Asbestos, cement, f o b, Quebec	short ton	15.00 -	17 00
Barytes, ground, white, f o b mills, barrels	net ton	16 00 -	20 00
Barytes, ground, off color f o b mills bulk	net ton	13.00 -	21 00
Barytes, floated, f o b St Louis, barrels	net ton	23.00 -	24 00
Barytes, crude f o b mines bulk	net ton	8 00 -	9 00
Casein, barrels, tech	lb	.12 -	14
China clay (kaolin) crude, f o b Georgia	net ton	6.00 -	8.00
China clay (kaolin) washed, f o b Georgia bulk	net ton	8.00 -	9 00
China clay (kaolin) powd, f o b Georgia, bulk	net ton	14.00 -	20 00
China clay (kaolin) crude f o b Virginia	net ton	8.00 -	12 00
China clay (kaolin) ground, f o b Virginia	net ton	13 00 -	20 00
China clay (kaolin), imp lump, bulk	net ton	14 00 -	20 00
China clay (kaolin), imp, powd, bulk	net ton	40 00 -	45 00
Feldspar, No 1 pottery grade, bulk	long ton	5 50	7 00
Feldspar No 2 pottery grade, bulk	long ton	4 00 -	5 50
Feldspar, No 1 soap grade bulk	long ton	7 00 -	7 50
Feldspar, No 1 Canadian f o b mill bulk	long ton	20.00 -	21 00
Graphite, Ceylon lump first quality f o b N Y, barrels	lb	.05 -	.05½
Graphite, Ceylon chip, barrels	lb.	.04 -	04½
Graphite high grade amorphous crude, bulk	ton	35.00 -	50 00
Gum Arabic, amber, sorts, bags	lb	.15 -	16
Gum tragacanth, sorts, bags	lb	.50 -	60
Gum tragacanth No 1, bags	lb.	1.75 -	1 80
Kieselguhr, f o b, Cal, bulk	ton	40.00 -	42.00
Kieselguhr, f o b N Y, bulk	ton	50.00 -	55 00
Magnesite, crude, f o b Cal, bulk	ton	12.00 -	15 00
Pumice stone imp, casks	lb.	.03 -	.05½
Pumice stone, dom., lump, barrels	lb.	.05 -	05½
Pumice stone dom, ground, barrels	lb	.06 -	.07
Shellac, orange fine, bags	lb.	.74 -	.75
Shellac, orange superfine, bags	lb.	.76 -	.77
Shellac, A C garnet, bags	lb.	.75 -	.77
Shellac T N, bags	lb.	.72 -	.73
Silica, glass sand, f o b Indiana, bulk	ton	1.75 -	2 50
Silica, sand blast material f o b Indiana, bulk	ton	2.50 -	5 00
Silica amorphous, 250-mesh, f o b Illinois, bulk	ton	17.00 -	17 50
Silica, building sand, f o b Pa, bulk	ton	2 00 -	2 75
Soapstone, coarse, f o b Vermont, bags	ton	7.00 -	8 00
Talc, 200 mesh, f o b Vermont, bags	ton	7.00 -	12 00
Talc, 200 mesh, f o b Georgia, bags	ton	7.50 -	12.00
Talc, 200 mesh, f o b Los Angeles, bags	ton	15.00 -	17.00

Refractories

Bauxite brick, 56% Al_2O_3, f o b Pittsburgh	ton	$45-50
Chrome brick, f o b Eastern shipping points	ton	50
Chrome cement, 40-50%, Cr_2O_3	ton	23-27
Chrome cement, 40 45%, Cr_2O_3, sacks, f o b Eastern shipping points	ton	23 00
Fireclay brick, 1st quality, 9-in shapes, f o b, Pa, Ohio and Kentucky works	1,000	43-46
Fireclay brick, 2nd quality, 9-in shapes, f o b Pa, Ohio and Kentucky works	1,000	39-41
Magnesite brick, 9-in straight (f o b works)	ton	70-75
Magnesite brick, 9-in arches, wedges and keys	ton	85-90
Magnesite brick, soaps and splits	ton	90
Silica brick, 9-in sizes, f o b Chicago district	1,000	48-50

Silica brick, 9-in sizes, f.o.b. Birmingham district	1,000	$50 53
Silica brick, 9-in sizes, f.o.b. Mt Union, Pa.	1,000	45–47
Silicon carbide refractory brick, 9-in	1,000	1,100 00

Ferro-Alloys

Ferrotitanium 15-18 %, f.o.b. Niagara Falls, N. Y.	ton	$200 00	$225 00
Ferrochromium, per lb. of Cr contained, 6-8% carbon	lb	11	11½
Ferrochromium, per lb. of Cr contained 4-6% carbon	lb	11½	12
Ferromanganese, 78-82% Mn, Atlantic seaboard duty paid	gross ton	100 00	105 00
Spiegeleisen, 19-21%, Mn	gross ton	38 00 -	39 00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb	2 00	2 25
Ferrosilicon, 10-15%	gross ton	38 00	40 00
Ferrosilicon, 50%	gross ton	75 00 -	80 00
Ferrosilicon 75%	gross ton	115 00	120 00
Ferrotungsten, 70-80 %, per lb. of contained W	lb	85	95
Ferro-uranium, 35-50 % of U, per lb. of U content	lb	6 00	
Ferrovanadium, 30-40 % per lb. of contained V	lb	3 50	4 00

Ores and Semi-finished Products

Bauxite, domestic, crushed and dried, f.o.b. shipping points	ton	$6 00	$9 00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	22 00	23 00
Chrome ore, 50%, Cr_2O_3, c.i.f. Atlantic seaboard	ton	18 50	19 00
Coke, foundry, f.o.b. ovens	ton	8 50	9 00
Coke, furnace, f.o.b. ovens	ton	8 50	9 00
Fluorspar, gravel, f.o.b. mines, New Mexico	ton	17 50	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	ton	$21 50	$22 00
Ilmenite, 52% TiO_2, per lb. ore	lb	01¼	01
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	45	
Manganese ore, chemical (MnO_2)	ton	75 00	80 00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y.	lb	70	75
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport	lb	06	08
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	11½	12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	11½	12
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	Nominal	
Rutile, 95% TiO_2 per lb. ore	lb	12	
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	8 50	8 75
Tungsten, wolframite 60%, WO_3 and over, per unit of WO_3, N. Y. C.	unit	7 50	8 00
Uranium ore (carnotite) per lb. of U_3O_8	lb	3 50	3 75
Uranium oxide, 96%, per lb. contained U_3O_8	lb	2 25	2 50
Vanadium pentoxide, 99%	lb	12 00	14 00
Vanadium ore, per lb. of V_2O_5 contained	lb	1 00	
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb	04½-	13¼

Non-Ferrous Materials

	Cents per Lb
Copper, electrolytic	14 65
Aluminum, 98 to 99%	22 00- 23 00
Antimony, wholesale lots, Chinese and Japanese	6 35
Nickel, ordinary (ingot)	36 00
Nickel, electrolytic	39 00
Nickel, electrolytic, resale	32 00 33 00
Nickel, ingot and shot, resale	36 00
Monel metal, shot and blocks	32 00
Monel metal, ingots	35 00
Monel metal, sheet bars	38 00
Tin, 5-ton lots, Straits	38 875
Lead, New York, spot	7 25
Lead, E. St. Louis, spot	$7 05
Zinc, spot, New York	7 25–7 30
Zinc, spot, E. St. Louis	6 90–6 95

OTHER METALS

Silver (commercial)	oz	$0 63½
Cadmium	lb	1 15
Bismuth (500 lb. lots)	lb	2 45
Cobalt	lb	3 00@3 25
Magnesium, ingots, 99%	lb	1 00@1 05
Platinum	oz	$118 00
Iridium	oz	240 00@275 00
Palladium	oz	65 00
Mercury	75 lb	72 50

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb
Copper sheets, hot rolled	20 00
Copper bottoms	30 00
Copper rods	19 75
High brass wire	18 75
High brass rods	16 75
Low brass wire	19 60

No. 1 yellow brass turnings	5 50@ 5 75
Zinc	2 25@ 2 50

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers warehouses in the cities named

	New York	Chicago
Structural shapes	$2 90	$2 90
Soft steel bars	2 80	2 80
Soft steel bar shapes	2 80	2 80
Soft steel bands	3 40	3 40
Plates, ¼ to 1 in. thick	2 90	2 90

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TUSCALOOSA—The Thress Brick Co., recently organized, has plans in progress for the construction of a new plant on local site, with initial capacity of about 60,000 bricks per day. A number of kilns, updraft type, will be constructed, with machinery installation to provide for a mechanical drying capacity of 600,000 bricks. The new plant is estimated to cost in excess of $50,000. J. H. Thress is vice-president and general manager.

TUSCUMBIA—W. T. Archer and Thurmond Harris, Tuscumbia, are planning for the organization of a company to construct and operate a cement mill and lime-manufacturing plant in the vicinity of the Keller quarry. The proposed works is estimated to cost about $200,000, with machinery.

BIRMINGHAM—The McWane Cast Iron Pipe Co. has filed plans and will commence the immediate construction of the first unit of its proposed new foundry, on site recently acquired at East Birmingham, to cost approximately $50,000. The plant will specialize in the production of small-sized cast iron pipe.

California

LOS ANGELES—W. P. Fuller & Co., 135 North Los Angeles St., manufacturers of paints, varnishes, etc., have plans in progress for the erection of a new 5-story and basement building, 180x250 ft., on San Bernardino Road, near Barranca St., to be used in connection with its local works. Morgan, Walls & Morgan, Van Nuys Bldg., are architects. The company recently awarded a contract for a similar plant building on Ave. 22, 120x125 ft., to cost about $45,000.

PITTSBURG—The Columbia Steel Co. has plans in progress for the construction of a new 6-mill sheet rolling mill at its local plant. It is estimated to cost close to $200,000 and will be equipped with modern electrically operated machinery in the different departments.

SALINAS—The National Stone-Tile Co., San Francisco, has preliminary plans under way for the construction of a local plant for the manufacture of hollow cement brick and kindred products.

SAN BERNARDINO—The Shell Oil Co., 343 Sansome St., San Francisco, is negotiating for property at the foot of F St., near Rialto Ave., approximating 30,000 sq.ft., as a site for a new distributing and storage plant, estimated to cost about $80,000, with equipment.

Colorado

COLORADO SPRINGS—The Van Briggle Tile & Pottery Co. is completing plans for extensions in its plant, to include the construction of a new kiln, and the installation of additional equipment. I. F. and J. H. Lewis head the company.

Florida

EUSTIS—A. J. Wolz & Sons, operating a local plant for the manufacture of brick and kindred burned clay products, are planning for the installation of additional equipment for plant enlargement. A new kiln will be constructed.

Georgia

ATHENS—The Georgia Brick Co. has plans in progress for the rebuilding of the portion of its plant recently destroyed by fire, with loss estimated at about $10,000, including equipment. H. H. Hinton heads the company.

Illinois

CHICAGO—The Goldsmith Brothers Smelting & Refining Co., 29 East Madison St., has completed plans and will soon commence the construction of its proposed new plant at Throop and 58th Sts., comprising two 1-story buildings, estimated to cost close to $200,000, with equipment. Frank D. Chase, Inc., 645 North Michigan Ave., is architect and engineer.

MT. VERNON—The Bitumacite Coal Co., 37 West Van Buren St., Chicago, W. W. Ketchem, president, has completed plans for the construction of a new 1-story plant on local site, 50x100 ft., for the manufacture of fuel briquets, estimated to cost about $55,000, with equipment.

Indiana

SHELBYVILLE—The Kennedy Paper Co. is taking bids for the construction of its proposed 1-story plant addition, 50x180 ft., estimated to cost approximately $30,000. Work will be placed under way at an early date. Rubush & Hunter, American Central Life Bldg., Indianapolis, are architects.

Kentucky

MARION—The Big Four Fluorspar & Ore Co., Farmers' Bank Bldg., Pittsburgh, Pa., has plans under way for the construction of a local fluorspar mining and milling plant with initial capacity of about 75 tons per day. It is estimated to cost approximately $100,000, including machinery. A. H. Reed is local manager.

PROVIDENCE—The Island River Fluorspar Co., recently organized, is considering plans for the installation of a local mining and milling plant, estimated to cost approximately $75,000. The company is capitalized at $250,000, and is headed by S. K. Holland and Thomas O. Long.

BOWLING GREEN—The Rock Asphalt Co. of America, recently organized, has preliminary plans in progress for the installation and operation of a plant in this vicinity for the production of commercial asphalt. W. E. Massey, Louisville, is president.

Louisiana

BASTROP—The Bastrop Pulp & Paper Co. is planning for the installation of additional machinery at its plant, for the manufac-

ture of kraft papers, and will increase the output about 50 tons per day. Work has been commenced on a new 1-story power house.

MONROE—The Southern Carbon Co is said to have plans under way for the construction of additional plant units to cost more than $1,000,000, with machinery.

Maryland

CAMBRIDGE—The Dorchester Lime & Fertilizer Co. will soon take bids for the construction of the first building at its local plant to replace the structures recently destroyed by fire It will cost about $30,000 Another building will be erected in the near future Webster N Andrews is general manager

BALTIMORE—The Inter-Ocean Oil Co is planning for the rebuilding of its gasoline storage and distributing plant at East Brooklyn, recently restroyed by fire with loss totaling $50,000, including equipment

BALTIMORE—A complete laboratory will be installed in the new school of hygiene and public health to be erected at the Johns Hopkins University, estimated to cost about $1,000,000 Archer & Allen Central Savings Bank Bldg are architects

Massachusetts

WORCESTER—The George C Whitney Co, manufacturer of paper products, will break ground at once for the erection of a 6-story plant addition, 55x60 ft, near School St to cost close to $50,000 Lockwood Greene & Co, 24 Federal St, Boston, are architects and engineers

BROCKTON The local plant of the Keith Oil Co was partly destroyed by fire recently with loss etsimated at about $12 000 It will be rebuilt

BOSTON—The Hunt-Spiller Mfg Co 383 Dorchester Ave, manufacturer of iron castings has work under way on a new 1-story plant addition, estimated to cost close to $30,000 The company recently took out a charter under state laws, with capital of 15,000 shares of stock, no par value Wallace L Gifford is president, and Robert F Blake, 212 Beacon St, treasurer

WOBURN—The Welch Japanning Co, Park St, will break ground at once for the erection of a new 2-story japanning works, 38x40 ft, at 38 Park St

SOUTH HADLEY The Holyoke Gummed Products Co 9 Suffolk St, manufacturer of gummed paper products will commence the immediate erection of a 1-story addition 140x147 ft, estimated to cost about $40,000. Contract has been awarded to the Austin Co, 217 Broadway New York Maurice Moriarty is treasurer

Michigan

PORT HURON The New Egyptian Portland Cement Co, 1213 Ford Bldg, Detroit, has commenced work on the remodeling of the former local railroad shops, lately acquired for a new cement-manufacturing plant The work with machinery installation, is estimated to cost in excess of $80,000 John A Decker, 708 State St Port Huron, is consulting engineer. John Gillespie is president.

ST CLAIR—The Diamond Crystal Salt Co has foundations in progress for a new 1-story plant addition, 50x150 ft, to be equipped as a machine shop and mechanical department Henry Whiting is president

Missouri

WEST PLAINS—The National Rendering Co., Kansas City, Mo, has plans under way for the construction of a new local plant for the manufacture of soaps and greases Tankage and fertilizer will be secured from the works of the West Plains Serum Co, Lincoln Ave. W R Ross heads the company.

CONTINENTAL—The Alpha Portland Cement Co., Easton, Pa., is planning for the erection of an addition to the plant of the Continental Portland Cement Co, recently acquired for a consideration said to be $1,000,000. The new unit will cost approximately $500,000, with machinery. The local mill will be the ninth plant to be operated by the Alpha company, and will be increased in capacity from 3,200 to 4,500 bbl per day

New Jersey

EAST NEWARK—The John Hewitt Foundry Co. has tentative plans under consideration for the rebuilding of the portion of its plant on Sherman Ave., destroyed by fire recently with loss estimated at about $10,000.

BOUND BROOK—The Rubberoid Co., a subsidiary of the Standard Paint Co., manufacturer of composition roofing, roofing paints, etc., has completed plans for the erection of a 1-story building at its local works, 100x120 ft.

NEWARK—The Pittsburgh Plate Glass Co., 290 Elizabeth Ave, has work in progress on the first unit of its new linseed oil mill at Riverside and Chester Aves., adjoining its paint works at this location. The plant, with grain elevators and machinery, will cost approximately $300,000, and will give employment to about 100 men It is expected to be ready for service early in March. Headquarters of the company are in the Frick Bldg Pittsburgh, Pa

TRENTON—The Jointless Fire Brick Co, 1130 Clay St, Chicago, Ill, has acquired a local site for the erection of a new fire brick and refractory plant, estimated to cost close to $75,000, with machinery. It will be equipped for an output of 2 carloads per day

New York

GOUVERNEUR—The W H Loomis Talc Co, Main St, has plans nearing completion for the erection of a new 1-story plant on local site, 40x110 ft, estimated to cost approximately $50,000, with pulverizing and other machinery W H Loomis is head

OGDENSBURG The Ogdensburg Paper Co has tentative plans under consideration for the erection of a new 1-story mill addition to cost about $150,000, including equipment George G McKee is in charge.

North Carolina

ALBEMARLE The City Council is taking bids until Jan 11 for extensions and improvements in the municipal waterworks, including filtration plant, with chemical house and other departments The Gilbert C White Co, Durham, N C, is engineer

Ohio

NILES The Ohio Galvanizing & Mfg C is taking bids for the construction of a new 1-story plant addition, 72x120 ft and will break ground at an early date. E F Bentley is head

CINCINNATI—Fire, Dec 17, destroyed two buildings at the plant of the Jarecki Chemical Co., at St Bernard, near Cincinnati, with loss estimated at about $150,000 including equipment and stock It is planned to rebuild

ALLIANCE Charles B. Smith and L C Cook of the Manufacturers' Sales Co, Alliance, have organized a new company to operate the pottery now in course of erection on site secured through the local Chamber of Commerce, between Sebring and Alliance The initial structure will be 1 story 85x200 ft, and will be devoted to the decorating of whiteware and chinaware products Two decorating kilns will be erected at the present time, and four additional such units at a later date It is planned to commence operations late in January

Oregon

SPRINGFIELD The Carbolineum Wood Products Co, Portland, has arranged for the establishment of a new wood-treating and creosoting plant on local site The present works at Alder will be removed to this location and additional equipment installed to provide a capacity of 1 carload per day

Pennsylvania

POTTSTOWN The Model Tire Co. has broken ground for the erection of a 1-story addition to its plant George H. Starkweather heads the company.

AMBRIDGE—The Standard Seamless Tube Co, 313 6th Ave., Pittsburgh, manufacturer of steel tubing, is considering the erection of an addition to its local plant to cost about $75,000 H E Wharton is company engineer

MIDLAND—The Pittsburgh Crucible Steel Co. has commenced the installation of a new liquid purification plant at its local works, to be equipped for a capacity of 12,000,000 cu.ft. It will be used to purify coke oven gases, and is expected to be ready for service early in March.

ALLENTOWN—The Royal Paper & Bag Co, 16 North 7th St., has authorized plans for the rebuilding of the 3-story plant, 60x230 ft., at 37-41 North 7th St., recently destroyed by fire.

Texas

HOUSTON—The Sinclair Refining Co. is said to have tentative plans under way for the erection of an addition to its oil refinery on the Houston ship channel for considerable increase in capacity.

PIONEER The American Oil Co., Tulsa, Okla., has commenced the erection of the first unit of a new refining plant on local site, and will inaugurate work on the second unit at an early date. The total plant will have an output of about 5,000 bbl. per day and is estimated to cost approximately $100,000. T J Ryans is president.

Virginia

GRAHAM Sutphin & Snell are planning for the establishment of a local plant for the manufacture of shale brick, with daily output of about 50,000 bricks Inquiries are being made for machinery and operating equipment

GALAX—Work will be commenced at once on a new filtration plant at the municipal waterworks, to have a capacity of about 500,000 gal gross The Carolina Engineering Co, Wilmington N C is engineer

Washington

OLYMPIA The West Coast Pulp & Paper Co, recently organized to construct and operate a local paper mill, will be operated by the same interests as control the Hawley Pulp & Paper Co, Oregon City, Ore In addition to the acquisition of a local site for the proposed new mill secured in co-operation with the Olympia Manufacturers' Association the company has purchased a former brewery at Tumwater and will remodel the structure for another paper mill The larger mill to be constructed will cost close to $750,000 instead of $500,000, as previously announced, and is expected to be ready for service in about 12 months

West Virginia

CHARLESTON The Libbey-Owens Sheet Glass Co, Nicholas Bldg, Toledo, O, is completing plans for the erection of the proposed addition to its local plant, to include a number of new buildings, with machinery, estimated to cost approximately $2,000,000 The Owens Bottle Co, same address, a subsidiary organization, is also perfecting plans for the new addition to its Charleston works comprising additional structures than those initially considered, increasing the estimated investment to about $750,000, with machinery The Devore Co., Nicholas Bldg, Toledo, is engineer for both projects and E D Libbey heads the companies

CHARLESTON—The Evans Lead Co is planning for immediate operations in the portion of its new local plant just completed, giving employment to about 100 workers The plant will specialize in the production of red and white leads Tentative plans are now under consideration for the erection of two additional factory units

Mexico

SANTA EULALIA—The San Toy Mining Co has tentative plans under way for extensions and improvements in its plant to cost about $100,000, including the installation of considerable new equipment An appropriation of the amount noted has been arranged Charles M Schwab, head of the Bethlehem Steel Co, Bethlehem, Pa, is interested in the company

Cuba

CAMAGUEY The Estrella Sugar Central, Ltd, has plans under consideration for the rebuilding of the portion of its mill and power house at Cespedes, recently destroyed by fire, caused by an explosion

Capital Increases, Etc.

THE ROESSLER & HASSLACHER CHEMICAL Co, 709 6th Ave., New York, has filed notice of increase in capital from $1,300,000 to $3,250,000

THE FRENCHTOWN PORCELAIN CO., Frenchtown, N J., manufacturer of electrical porcelain products, has arranged for an increase in capital from $100,000 to $350,000.

THE BOYDELL BROTHERS WHITE LEAD & COLOR CO., 432 East Lafayette St., Detroit, Mich, has filed notice of increase in capital from $150,000 to $337,500 for general expansion.

THE INDIANA ZINC CREOSOTING CO., Terre Haute, Ind., has arranged for a change of name to the Indiana Wood Preserving Co.

THE UNION CARD & PAPER CO., 45 Beekman St, New York, N. Y., has arranged for an increase in capital from $150,000 to $500,000.

THE PERTH AMBOY CHEMICAL WORKS, INC., 71 Buckingham St., Perth Amboy, N. J., has filed notice of increase in capital from $40,000 to $1,000,000 for proposed expansion.

Industrial Developments

PAPER—All of the paper mills at Windsor Locks, Conn., have adopted a capacity schedule, covering day and night forces on an 8-hr shift. The plants include the American Writing Paper Co., C. H. Dexter & Sons, and the Windsor Locks Paper Mills, Inc., the last noted being operated by J. L. Smyth Co., New York.

Paper and pulp mills at Fort William, Ont., have increased operations and are now running on a heavier production schedule than for a number of months past.

The Spruce Falls Co., Kapuskasing, Ont., has completed the construction of a local sulphite pulp mill and will operate at the plant at maximum capacity for an indefinite period.

CERAMIC—A complete settlement has been effected in the general ware branch of the pottery industry, following a 10 weeks strike, with a compromise wage advance of 1½ per cent over previous schedule. The men asked for a 7 per cent increase.

The Creighton Brick & Tile Co., Creighton, Mo., is perfecting plans for the early resumption of production at its local plant following a shut-down for a number of months.

The Independent Brick Co., Trenton, N. J., is maintaining active operations at three of its four brick manufacturing plants at Bordentown and vicinity, and expects to continue on this basis throughout the winter season.

The Kenyon Brick & Tile Co., Oklahoma City, Okla., is continuing production on a capacity schedule, and purposes to make a number of plant additions to develop a maximum of 40,000 bricks per day, as well as building tile and other burned clay products.

General ware potteries at Trenton, N. J., are advancing production, following the settlement of the strike with the operative potters. Philadelphia, Pa., potteries are also increasing their outputs, and the majority of plants in this district are now running close to 100 per cent.

The Perth Amboy Tile Co., Perth Amboy, N. J., is maintaining full capacity at its local works and has extensions under way for early increase.

The Birmingham Hollow Tile Co., Ensley, Ala., is running full, with regular working force. Orders on hand are said to insure continuance on this basis throughout the winter season.

The Standard Brick Mfg. Co., Evansville, Ind., is running at both of its plants at normal capacity, and plans to continue at least one of the factories in service during the winter months.

RUBBER—The General Tire & Rubber Co., East Akron, O., is completing the erection of three new plant additions at its local works, and proposes to place the units in full service in January or February. The present output is on a basis of 2,500 tires daily, and this production will be doubled as soon as the new units are ready.

The Kelly Springfield Tire Co., Akron, O., is maintaining production on a capacity schedule and will continue on this basis for an indefinite period.

METALS—Following the closing of a contract with the American Smelting & Refining Co. for the purchase of its entire output of zinc concentrate for a period of 5 years, the Callahan Zinc & Lead Co., Coeur d'Alene, Idaho, is arranging to increase production at its local plant. The Callahan company has acquired a substantial interest in the Galena Mining Co., operating in this same district, and proposes to advance the output at the works.

The Bay View Foundry Co., Sandusky, O., is arranging for the reopening of its plant early in January, after a shut-down for more than 4 months.

The International Nickel Co. has advanced production at its Port Colborne, Ont., plant to the highest point since the close of the war, giving employment to a large increased working force. For the first time in 4 years the entire production of Monel metal is being shipped from the plant.

The brass foundry of the New Holland Machine & Foundry Co., New Holland, Pa., has increased production to a full time basis, giving employment to the regular working force for the first time in a number of weeks past.

The Mohawk Mining Co., Calumet, Mich., is running two heads at its stamp mill, under a 3-shift working day, on a production schedule of handling 36,000 tons of rock per month.

IRON AND STEEL—The Woodward Iron Co., Woodward, Ala., is arranging to blow in its No. 1 furnace early in January. The unit was closed down recently for necessary repairs.

The National Tube Co., Pittsburgh, Pa., a subsidiary of the United States Steel Corp., is advancing operations at its Riverside works, Wheeling, W. Va., a plant that is used for reserve service in times of heavy demand. Both blast furnaces have been blown in, while two bessemer converters are operating, five of seven welding furnaces will also be active for an indefinite period.

The Minnesota Steel Co., Duluth, Minn., is running on a capacity basis and will continue on this schedule for an indefinite period.

The Trumbull Steel Co., Youngstown, O., is developing increased production, and record shipments are being made from the mill. A new high average was attained in November, with a moved finished tonnage of 32,000 tons of sheets, strip steel and tin plate. A full working force is being employed.

The Carnegie Steel Co., Pittsburgh, Pa., has blown in several additional furnaces during December, and will soon have 15 or 16 stacks in blast.

In the district bounded by Johnstown, Pa., Wheeling, W. Va., and Warren, O., a total of 99 blast furnaces out of 139 stacks are now in operation, the largest number in more than 2 years.

The Republic Iron & Steel Co., Birmingham, Ala., has two furnaces in blast at its local works and will keep the stacks active for an indefinite period. The Central Coal & Iron Co., in this same district has one stack in service, as has also the Alabama Co.

MISCELLANEOUS—The Oak Extract Co., Newport, Pa., manufacturer of sulphuric, nitric and other acids, has resumed operation at its plant, following a curtailment for several months due to difficulty in securing raw materials.

The Taylor Brothers Co., Rockdale, Tex., has completed the installation of equipment for an increase from 75 to 100 bbl. per day at its oil-topping plant and has placed the unit in service on a full production basis.

Cotton oil mills at Charlotte, N. C., and vicinity have increased production to full-time basis operations, and will maintain this schedule until early in February.

The Corn Products Refining Co. is giving employment to a total of 650 persons at the new mill at North Kansas City, Mo., on a full-time operating basis.

New Companies

THE HEDGES & DIVINE ZINC CO., 3039 East 92nd St., Chicago, Ill., has been incorporated with a capital of $30,000, to manufacture zinc and other metal products. The incorporators are M. J. J. Rieck, C. W. Kraft and F. A. Thulin.

THE HUDSON ALCOHOL CO., West New York, N. J., has been incorporated with a capital of $10,000, to manufacture denatured alcohol and kindred products. The incorporators are Nicholas and Dominick Curcio, 761 Bergenline Ave., West New York. The last noted represents the company.

THE GREENWICH CHEMICAL CO., New York, N. Y., care of S. V. Ryan, attorney, Albany, N. Y., representative, has been incorporated with a capital of $200,000, to manufacture disinfectants, insecticides and other chemical products. The incorporators are S. C. Wood and H. C. Hand.

THE ALBERT H. BECK CO., Philadelphia, Pa., has been incorporated with a capital of $50,000, to manufacture glass products. R. M. Beck, 3335 North 7th St., Philadelphia, is treasurer and representative.

THE RAYNAUD CONRAD PAINT CO., New Orleans, La., has been incorporated with a capital of $100,000, to manufacture paints, varnishes, oils, etc. The incorporators are Joseph Raynaud, C. Carlisle Conrad and George Steck, all of New Orleans.

THE WILLIMANTIC RIVER PAPER CO., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $375,000, to manufacture paper products, with mill in New England.

THE CHARLES WALSH CO., Philadelphia, Pa., has been incorporated with a capital of $50,000, to manufacture brick, tile and kindred products. F. E. White, 6132 Lebanon Ave., Philadelphia, is treasurer and representative.

THE KEENE CHEMICAL CO., New York, N. Y., care of S. S. Winter, 261 Broadway, New York, representative, has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are S. M. Morecy, J. Weissbaum and E. H. Barker.

THE SOUTHERN ATLANTIC FERTILIZER CO., Augusta, Ga., has been incorporated with a capital of $15,000, to manufacture fertilizer products. The incorporators are R. C. Neely, Sr. and Jr., and S. H. Wilcox, all of Augusta.

THE ANT-ROACH POWDER CO., Newark, N. J., has been incorporated with a nominal capital of $5,000, to manufacture insect powders and other chemical specialties. The incorporators are Edward H. Zimmerman, George C. Weber and John A. Berringer, 83 South Orange Ave., Newark. The last noted represents the company.

THE RAYDNT CORP., Pittsburgh, Pa., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws with capital of $25,000, to manufacture varnishes, polishes, etc.

THE AMAREX CORP., New York, N. Y., care of Holmes, Rogers & Carpenter, 20 Broad St., New York, representatives, has been incorporated with a capital of $20,000, to manufacture chemical products. The incorporators are F. Ferranti and O. Rodinella.

THE PITTSBURGH OIL & REFINING CO., Pittsburgh, Pa., is being organized to manufacture refined oils. The incorporators are Robert A. Rundle, George Faunce, Jr., and Clyde D. Beistel. Application for a state charter will be made on Jan. 8. The company is represented by J. Merrill Wright and Robert A. Rundle, 624 Frick Bldg., Pittsburgh.

THE L. J. TILLERY OIL CO., Beaumont, Tex., has been incorporated with a capital of $85,000, to manufacture petroleum products. The incorporators are L. J. Tillery, J. D. Campbell and C. G. Hooks, all of Beaumont.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 2 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1923.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 15 and 16, 1923.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Volume 28 New York, January 10, 1923 Number 2

Problems in the Production of Sodium Sulphide

DURING the years 1917 to 1920 there was an annual production of sodium sulphide in this country of 45,000 tons. The size of this industry has been the cause of considerable surprise, for it is not generally recognized that sodium sulphide is so important a commodity. It is obtained both by the reduction of salt cake, sodium sulphate, with coal, and as a byproduct of the barium industry. Since the ultimate survival of the barium industry in this country is at least partly dependent upon the tariff, it cannot be regarded as a basic source of sodium sulphide. Future progress in production, therefore, is rather definitely limited to improvements of the technology of the salt cake process.

The furnacing of salt cake to produce sodium sulphide is a good example of a common type of problem met in chemical industry. The technology is surprisingly primitive and improvements are easy to visualize. But when it comes to the point of changing the process, it is impossible to show *a priori* a distinct advantage for the improvement, even on paper, because of the many variables. Moreover, the industry is bound by conservatism to an extraordinary extent.

At present salt cake is mixed with about half its weight of coal and treated in a rotary or reverberatory furnace. The material is gradually heated until it melts and reduction begins. As the reduction nears completion the mass becomes more and more solid until finally the charge is dumped and the cycle is repeated.

Perhaps the first thought that occurs to the average chemical engineer who observes this process is to make it continuous. But a continuous process must take care of all three stages—preheating, fusion and reduction. The character of the charge changes fundamentally during the reaction from a mixture of finely divided solids to a mobile liquid and partly back to solid again. To attempt to carry out such a reaction in a rotary furnace would require a much longer one than is at present used, the operation being perhaps analogous to that of cement burning. But the changes of state which the charge undergoes would present grave if not insurmountable operating difficulties and these would be enhanced by the fact that sodium sulphide burns rapidly after the reduction is complete.

Thus the time factor is seen to be of vital importance. This is the reason why the continuous process used for the reduction of sulphate in the paper industry cannot be applied to the manufacture of sodium sulphide, for in the paper industry reduction is not complete and the presence of sodium carbonate, the product of sodium sulphide decomposition, does not represent a serious loss.

Other methods, which get away entirely from the rotary furnace process, have been suggested. One of the most promising consists in injecting a finely divided mixture of coal and salt cake at the top of a stack. The tower would be heated by means of tuyeres and the mixture would work to the bottom where the products would be removed. The improvements in yield and replacement cost which would result from this or any other radical change can be estimated only after complete investigation. Meanwhile the cost of the investigation, the high investment in present equipment and the lack of any positive assurance of satisfactory results have held back investigation and consequently defeated progress.

Long-Term Credits And the Fertilizer Industry

PROMINENT men in the fertilizer industry have stated frequently during the past 2 years that the sale of fertilizer on long-term credit is one of the very serious problems. Stated briefly, the situation is this: Fertilizer is delivered before the crop is planted and paid for after the crop is sold. If, as in 1921, there were large financial losses and many failures on the part of the farmers, the bills would not be paid until the harvesting of the next year's crop. Naturally this would have to affect the price of fertilizer during the following year, as at least the interest on the money involved would have to be absorbed.

Several statesmanlike addresses have been made on the subject to fertilizer manufacturers in which the imperative need for doing cash business was urged. It is a real handicap for the industry to have to act as banker for its consumers and it militates against the proper development of local banking. Of course historically the industry has only itself to blame. For the practice was started in order to increase sales and to establish the confidence of the consumer in the product. Now the producer can't let go. During this last year an increase of cash business has been reported, but we learn from those associated with the industry that it is very doubtful if it will ever be able to emancipate itself from the granting of long-term credits.

To the outsider it looks as though severe competition actually has proved undesirable for the consumer, which is a peculiar anomaly. So anxious is the individual manufacturer for business that if one producer were to offer cash terms only, the customer could shop for material elsewhere and get it on the old terms, which almost amounts to "pay when you get ready." So the net result is that because of intense competition the industry must still adhere to the antiquated procedure and carry the customer till after harvest. This must cost the customer more than straight interest which he would pay as discount on a commercial loan at a local bank, for there is much more risk for the manufacturer than there would be for the local banker, who is in

closer touch with conditions. Here is a case where a gentleman's agreement ought to be of distinct benefit to the consumer, to say nothing of the producing industry.

Our Problem Of Immigration

SINCE 1882, when Congress passed the first general immigration law, this country has been experimenting with various measures designed in one way or another to curb or limit the incoming stream of foreigners. In all that time, however, we have never formulated what might be regarded as a permanent immigration policy. To find the reason for this it is necessary to go back a bit into history.

In the past 40 years our attitude toward immigration has completely changed. For several decades before the war the subject was regarded purely as an economic problem and the immigrant's effect on American industry and American wages was the paramount consideration. Little thought was given to the social aspects of immigration; the capacity of our great melting pot was believed to be unlimited. But the developments of the war very abruptly changed our viewpoint. The racial characteristics and the quality and character of the incomers were more carefully studied. Their attitude toward American institutions and toward our standards of living completely overshadowed any economic questions involved. Already it had become apparent that there was danger of too much infusible material in our melting pot and that slag inclusions were threatening to weaken the pure metal of American citizenship.

This change in attitude was to some extent attributable to a very important change that has occurred in the character of immigration. From 1870 to 1890 practically 90 per cent of our immigrants were of the Nordic races, coming from northwestern Europe—including the British Isles, Germany, Scandinavia, Belgium, the Netherlands and France. But about 1900 a different trend became evident and the Slavic races appeared on our shores in ever-increasing numbers. Soon Italy, Austria-Hungary, Greece and the other countries of southern and eastern Europe were supplying as much as 80 to 85 per cent of all our immigrants. And these newer arrivals were less stable, inclined to be radical and somewhat more than a third of them were illiterate. Furthermore, they were not readily assimilated.

While the Nordic immigrants had gone largely to the farms and factories, the Slavic were generally unskilled laborers and were satisfied to remain so. Still another complication in recent years has been the increase in the proportion of Jews of a type inclined to enter trade rather than industry or agriculture.

The present 3 per cent immigration law, admittedly an emergency measure, has not contributed a great deal to the situation. Designed to limit admission from any particular country to 3 per cent of the number of that country's nationals shown in our 1910 census, the law made the fatal mistake of failing to take into account the number who returned to their former countries. This accounts for such inconsistencies as the admission of only 42,000 Italians last year during a period when 58,000 former immigrants actually returned to Italy. The principal good that has come from the present law, however, has been the material reduction in the proportion of undesirables. Southern and eastern Europe, instead of supplying 750,000, as in many past years, was limited under the quota law to 155,000. Needless to say, the quotas from these countries are always filled. Thus the maximum number of Greeks and Turks to be admitted during the year ending June 30, 1923, had already been supplied as early as November, 1922.

As the present business revival continues there is a clamor in many industries for more workers—in fact, it cannot be doubted that in many localities there is an actual dearth of unskilled labor. Pressure is being brought to liberalize the immigration laws, to let down the bars in order to satisfy the economic needs of the country. As a nation it would seem that we are confronted with the problem of polluting our blood stream in order to get economic relief or of preserving our blood stream pure and suffering an economic loss.

What, then, is the way out? In formulating a permanent economic policy toward immigration (and we can never get anywhere until we do) we are confronted with the necessity of effecting a working compromise between these views. But, at the same time, a number of other factors must be considered. Qualitative selection of the immigrants to be brought in and their intelligent distribution after they arrive would certainly seem advantageous. After excluding the undesirables, the aliens in the country might be registered and their movements followed closely for the first year or so in order to observe their progress in Americanization and their industrial occupation and service. Finally, it might be possible for an immigration commission to keep informed about available supplies of foreign labor, in order that we might know where to turn for the sort of man power needed by our industries.

While the framing of an immigration policy is still in a formulative stage, those of us in industry can contribute to the situation by making the closest study of our own labor problems in their particular relation to the foreign-born worker. It will be only when we can furnish our legislators with definite quantitative information regarding labor shortage, turnover and efficiency and interpret this in terms of nationality, race and length of service that we can expect to have a scientific solution of our immigration problem.

The Menace of Loosely Drawn Contracts

PROBABLY a vague security is felt by a manufacturing organization in contracting for all of its "requirements" in a given commodity, for the practice is widely followed. In many cases it is harmless, as when a relatively large producer agrees to take care of a relatively small consumer. In such a case the maximum requirements of the consumer will hardly be an appreciable percentage of the producer's output. But where producer and consumer are more nearly the same size and where variations in consumption may be a relatively large percentage of the total output, the contract must be drawn with considerable care. Loosely drawn contracts are especially a menace in such a case and the court records are filled with disputes about them. Exactly the same thing is true of the converse, where the total output of a factory is contracted for. The many cases cited by WELLINGTON GUSTIN elsewhere in this issue strikingly confirm this fact.

The reasons back of the practice of making loosely drawn contracts are probably more fundamental than mere carelessness or ignorance. There is a tendency to believe that in vagueness of expression lies a flexibility from which advantages may accrue. It is usually forgotten that flexibility is a two-edged sword and that the advantage may lie with the other party. In addition there is also the contract which does not express ac-

curately the purposes of both parties. This is caused by loose thinking which makes for inaccurate wording. Such a contract may be made with perfect good faith on both sides.

Nothing more completely destroys the friendly good will which is the leaven of business relations than a dispute about money—a dispute in which both sides feel that they are being wronged. Mr. GUSTIN'S article is of great value because it focuses attention on a fundamental principle which must be periodically called to mind. Good faith alone is not adequate in business dealings, but must be supported by accurate expression and complete understanding in and through business contracts. Good contracts are promoters of business health.

Dirt In Steel

PRIOR to the war most all steelmakers thought that slag and metal had some mutual repulsion, like oil and water. They would not mix, and if you gave the metal a chance to settle quietly in the furnace, ladle or even in the ingot mold, all the slag would gather on top, separated clearly from metal free of the last traces of slag. Then if the ladle and mold were clean of dirt, the resulting steel would be sound, except perhaps for a few surface seams or blisters which perhaps were healed in rolling, some blowholes which could always be welded shut, and maybe some pipe or shrinkage cavity in the top, which could be cropped.

Some steelmakers, and big ones at that, think so yet. They are sure that those little black spots which must be hunted for with a microscope cannot have any influence on the quality of steel; things so little don't count. Anyway, the chemical analysis is all right—sulphur and phosphorus are both low. Gas? "Why, how can there be any gas in that solid, dense metal? Besides a cubic foot of gas is almost too light to weigh, and that much steel weighs 500 pounds; if there ever was any in the blowholes it is all squeezed out. You scientific men are always looking for troubles which do not exist—here's good, sound dependable metal we can make in large tonnage. Why are you so fussy about it? Perhaps there's a bad piece in it now and then, but we'll gladly replace those, and it's good uniform stuff. We stake our reputation on it. Would you think that Professor Micrograph knows more about steel making than our experts and the combined lifelong experience of the Tonnage Steel Co.? If a ½-in. section gives you a few failures, use a ¾-in. section."

But there are some problems which can't be solved that way. During the war, recoil cylinders and gun tubes had to be made in great numbers, strong against great bursting pressures and yet light enough to be manageable in field pieces. And for the life of them, the Tonnage Steel Co. and all its experts could not pass the inspection more than ten times in a hundred. Alloy steels were blamed. If only carbon steel were specified, of course that would have been a different matter!

The war is over, but like the peace such metallurgical troubles are still with us. We are more and more interested in high-speed transportation. Forgetting airplanes and subways (although the matter applies to them as well), automobiles are driven at 50 miles per hour oftener than they were sent 35, five short years ago. Every increase in speed increases the required power much faster, throws stresses into each member at a greater rate and searches out hidden defects in all parts ceaselessly. So the world moves, and because a certain brake drum made from Tonnage Steel Co.'s carbon steel has been turned out by the million, there is no reason to suppose that that design is the best there is, that it will be used forever, or that disastrous failures will never occur with faster and faster driving.

In fact, such a condition actually exists. We have in mind a manufacturer of a very fine automobile which has built up an enviable record for quality and reliability. Each part going into the machine is carefully made, under constant and minute inspection; stock parts are tested by lots before assembly and each finished car is taken out on a test run by a driver determined to jar loose anything that is loose. Production had practically been standardized, yet without any very great difference observable in the routine tests, the number of failures during test runs gradually increased in both carbon and alloy steel parts to an alarming proportion. What was worse, reports of one or two failures in service began trickling back.

After intensive investigation the cause of these failures was found to be almost invariably the same as the cause of our old enemy "flakes" in alloy steel: dirt. Close visual inspection of finished parts or fresh fractures would not reveal any sign of trouble. Nor would there be anything wrong in the chemical analysis. Microscopic examination of etched samples seemed also to give acceptable structures—not particularly free from ferrite banding and ghosts, and yet not noticeably worse than acceptable material. However, a polished unetched section invariably shows a great number of round black spots apparently hidden by etching, many $\frac{1}{16}$ in. across or larger and not more than ¼ in. apart at 100 magnifications. Often these are arranged in rows, whereupon a service-fracture would follow a series of these rows and exhibit an appearance of stairsteps. If a broken connecting rod was pickled deeply, all manner of seams appeared, apparently the vestiges of laps, pipes and unwelded blowholes.

Of course, the Tonnage Steel Co. would not accept the blame, nor be held to a specification demanding less dirt. It wouldn't admit that any dirt was there! But less conservative concerns were willing to make smaller heats of steel, exerting the most extreme care and the utmost resources of modern electrometallurgy. The result, while not perfectly clean steel, is certainly far ahead of anything to be had on the open market. And the proof of the matter is this: that when a troublesome part is made of clean steel, alloy or carbon, failures suddenly cease!

So, at the present time, most of the energies of the metallurgists of that motor company are devoted to an endeavor to get cleaner steel for forgings and bar stock. Their specifications now read, in effect, "The steel shall be free of blowholes, internal defects and solid non-metallic inclusions—the purchaser to be the judge of this requirement." Microscopic sections are taken of all highly stressed parts regularly and examined for dirt. It has even been found necessary in a number of cases to specify steel made by certain processes as being superior to ordinary material in the matter of cleanliness and cleanliness only. It has been found that certain makers furnish far cleaner steel than others, apparently as well equipped. They get the business.

Viewing this compelling fact, we take hope that eventually the Tonnage Steel Co. will become convinced that dirty steel is not a mere scientific speculation.

British Chemical Industries

From Our London Correspondent

London, Dec. 20, 1922.

CHEMICAL markets continue in quite a cheerful and healthy state and there is nothing abnormal about the usual falling off of business because of the Christmas holidays and stock taking. There is no doubt that the demand for general and heavy chemicals is likely to be greater in the New Year not only on account of the general improvement in the industrial outlook but also because of the government's roadmaking and shipbuilding programs and the schemes for the relief of unemployment. The threatened wage dispute in the chemical trade has also been avoided for the time being, and all these factors, together with the continued fall in contract prices for heavy chemicals, justify a considerable amount of optimism.

Briquetting Plants Close Down

The position in regard to pitch is at the present time one of peculiar interest. A few months ago the price was $5.50 per ton and since then it has been rising steadily until a level of about $12.50 per ton was reached. The reasons for this enormous increase are not only the closing down of a number of coke-oven plants but an increase in the demand for pitch for roadmaking purposes and the probability of a still further demand as progress is made with the government's program of additional roads and maintenance throughout the country, part of which is in relief of unemployment. Bitumen, of course, has been increasingly used owing to the pitch shortage, but a certain amount of pitch seems to be indispensable in the mixtures usually adopted for making coal briquets. The result has been rather curious, inasmuch as the manufacturers of briquets and patent fuel for anthracite slow-combustion stoves and the like have been unable to pay the high prices demanded for pitch and a number of briquetting plants have had to close down. This has already steadied the advance in prices, but the situation is very uncertain.

Progress in China Clay Industry

The past year has witnessed a remarkable recovery in the china clay industry, the quantity marketed representing more than 75 per cent of the pre-war production and the export trade having been more than double that of 1921. Cornish methods of handling china clay and refining it for the market have always appeared crude and inefficient to the uninitiated. Furthermore, some of the improved machinery installed just before the war was requisitioned by the government. The improvement in consumption has revived interest in improved methods, but it is unlikely that economies are really practicable except as regards fuel and improved grading of the finished product. The new plant of the Standardized China Clay Co. is about to begin operations and comprises four 36-in. Gee centrifugal separators, in which the china clay is automatically divided into four or more grades both as to fineness and quality, the coarser product containing a higher percentage of silica and other impurities. At the same time moisture is brought down to as low as 25 per cent in the machines and an improved gas-heated drier leads to further economies. The high-grade material from these machines commands a considerably enhanced price and it merely required standardization and educational propaganda to enable an increased over-all [illegible] to be obtained. There is also the possibility of further purifying and regrading the inferior product from these machines.

The further study of china clay for its use in chemical manufacture as distinct from those in paper making, pottery, cotton goods and so forth seems well worth while, as there is ample scope for widening the china clay market.

Sulphur Dioxide in Coal Mining

Coal mining is one of the few industries in which the chemist has not yet penetrated, but a recent investigation by Dr. Lessing has opened up the possibility of using purely chemical means instead of explosives or mechanical cutters, which have hitherto been regarded as irreplaceable. In 1882 the hydration of quicklime was suggested, the expansion acting as a mild explosive in shattering coal. The present suggestion, which is now being tried out on a practical scale at the Brereton Colliery, is that of passing moist sulphur dioxide gas through acid-proof tubes into the bore holes and allowing it to permeate through the coal for some hours. The gas is avidly absorbed by the coal and the calcium and other carbonates, which constitute the bulk of the interfacial layers or partings which cement the coal together, are decomposed, whereupon the coal can be very rapidly broken up and removed. It is stated that 1 ton of sulphur dioxide should suffice for 1,000 tons of coal, corresponding to about 5 cents per ton, and that there is no trace of leakage of gas into the atmosphere of the mine, although in any case the quantity of the gas used would be insufficient to produce injurious effects. Treatment in this way also seems to raise the ignition temperature of the coal after treatment and may therefore constitute a safety factor in coal mines apart from the possibility of replacing explosives by chemical methods of disintegration. The details of routine operations on a large scale should not be difficult to elaborate, but considerable interest has been attracted to the process and to the experiments which are now in progress, especially in mining districts where sulphur dioxide gas is or may be a waste product.

Other Industrial Developments

Other recent industrial developments include the use of carbon dioxide from the waste combustion gases of greenhouse boilers, for the purpose of increasing the yield of tomatoes, cucumbers and other hot-house products by approximately doubling the carbon dioxide content of the air in the houses. The possibility of applying this principle to crops in the neighborhood of blast-furnace plants is foreshadowed and two installations are in course of erection. A new process for utilizing blood and tankage for molded articles, insulating purposes and impregnation is being tried out and will be referred to in a subsequent contribution.

The Federal Council for Pure and Applied Chemistry has now published an appeal for funds to enable it to develop its work on an adequate scale. It is pointed out that while today's financial conditions prevent the realization of the large scheme outlined by the late Lord Moulton, it is now essential to make a beginning in the direction of the compilation of chemical compendia and for the cultivation of the social side of chemistry. In this connection the Council has given its official blessing and its co-operation to the excellent work of the Chemical Industry Club, which has just held its very successful fourth annual dinner, at which T. R. Duggan, of the Chemists' Club, New York, was an honored guest.

Microscopy of Paint And Rubber Pigments*

By Henry Green
Research Laboratory, New Jersey Zinc Co.

A New Conception of the Place of Microscopy in the Examination of Pigments Involving a Distinct Technique — Uncanny Insight Into Manufacturing Processes Is Made Possible by Development of Science

LIKE ANY SCIENCE, microscopy is composed of distinct divisions, from each of which a separate art is derived; so we find useful application made of the microscope by the bacteriologist, the petrologist, the metallographer, etc. There is one division, however, which, in comparison with the others, is still very much of an infant; in fact it has not even been christened. For convenience it will be called "pigment microscopy." Undoubtedly there exists sufficient literature on this subject to establish it as a distinct and useful branch of microscopy in itself, but the tendency has been, apparently, to treat it, not as a branch of microscopy at all, but rather as a problem incidental to more important ones in the domain of paint and rubber research.

The plan in presenting this paper has been to reverse the customary procedure and study the subject of pigments mainly from the microscopist's viewpoint, and incidentally point out its utilitarian aspects for the benefit of paint and rubber investigators.

As there is nothing in particular about a *mass* of pigment sufficiently characteristic to be of interest to the microscopist, his endeavor will naturally tend toward an attempt at resolving this mass into its ultimate units or *individual particles*. It is natural to expect that here might be found something that would not only differentiate various pigments but, in addition, throw some light on their behavior when subsequently used in paint or rubber.

The simple procedure of studying the individual pigment particle under the microscope seems like such an obvious thing to do that one would expect that nearly everything in this line had been accomplished some time ago. As a matter of fact, the number of technologists interested in the use of pigments having a clear conception of the appearance and particle size of such materials is almost negligible. About 5 or 6 years ago it was practically impossible to find a paint manufacturer even willing to admit that pigment particles could be seen in this manner. Perhaps a quotation from Bottler and Sabin[1] will help to visualize the situation as it stood then. Sabin states in reference to a microscopic examination of the major portion of elutriated basic carbonate of white lead (one of the coarser pigments):

> . . . and as to the residue comprising portion 5, which makes up the greater part of the pigment, it is not merely hopeless, it is as absolutely impossible (to measure) as it is to "average" the apparent size of the stars in the sky, where each increasing telescopic power reveals new infinites of star-dust.

And again,

> A microscope is an interesting and useful instrument; but the person who uses it is sometimes neither interesting nor useful, and microphotographs may be made and interpreted in all sorts of ways.

All of which indicates that the technologist believed then (and even now, in most cases) that pigments were too fine grained to be seen under the microscope.

Distinctive Technique

When it is taken into consideration that microscopists have for years devoted a considerable part of their time to the study of the minute structure of test diatoms, to the resolution of Nobert lines and to test plates, etc., it is not so obvious why technologists, though admittedly not trained microscopists, should have been unable to cope with a subject as "easy" as the coarser pigments. The answer lies in the fact that pigment microscopy is in itself a distinct division of the parent science. If we do not expect the metallographer, for instance, to excel, without previous preparation, in the use of the petrographic microscope, or the petrologist to feel at home in the bacteriologist's laboratory, then it is unfair to criticise adversely the investigator possessing but a temporary interest in the subject for not having acquired a correct technique for the successful microscopic analysis of pigments.

Recently there have been appearing indications of a keener interest in the subject of pigment microscopy than heretofore. This has been particularly true in the rubber industries. With this in mind and hoping to stimulate further research in this field, the necessary apparatus, methods of mounting, photographing, etc., for such work will be described. It is not to be inferred that this information is exclusively for the rubber investigators, for with few exceptions it will be of a general nature intended for use by anyone interested in pigments.

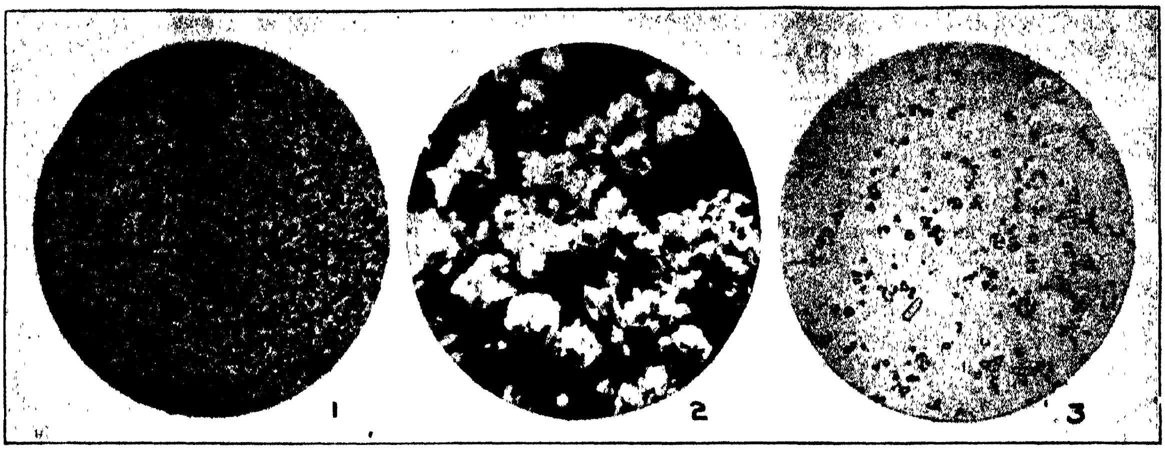
Apparatus Used in Pigment Study

The investigator working in the laboratory of a company either using or manufacturing pigments can gain for himself considerable knowledge of the nature of these materials by simple visual observation with the microscope. However, if this information is to be passed on to various department heads, etc., who seldom, if ever, visit the laboratory, the easiest procedure is to resort to photography; by this means a permanent record of what has been seen is obtained that is often easier to understand than any verbal or written description. Bearing this in mind, the beginner should acquire his apparatus and develop his laboratory accordingly, for eventually, when fully equipped, photomicroscopy will constitute the chief part of his work.

It is convenient, though not absolutely necessary, to have two microscopes. One is to be used for visual work for examining mounts, to note if they are properly dispersed. The second instrument is permanently fixed to a photographic stand and is to be used only for taking photomicrographs. The best stand is the upright type in which the camera can be swung aside to enable the operator to look into the microscope and

*Presented before the Technical Photographic and Microscopical Society, New York, Sept. 14, 1922.

[1] "German and American Varnish Making," by Bottler and Sabin.



FIGS 1, 2 AND 3

Fig. 1—This photomicrograph is an attempt to duplicate the kind often appearing in print and illustrates the following faults: 1—Magnification and resolving power both too low. 2—Illumination off center. 3—Illumination not critical. 4—Out of focus. 5—Overexposed. 6—Overdeveloped. 7—Pigment not dispersed.

Fig. 2—A fine grain pigment as taken from its package. Each pellet contains many thousands of pigment particles. Magnification 25 diameters.

Fig. 3—American process zinc oxide taken at 1,500 diameters, showing the characteristic crystalline outlines.

adjust the illumination, which, of course, must be maintained critical and centered. Each microscope should contain its own set of lenses, comprising a 16, 4 and 2 objective and a medium- and high-power eyepiece. A well-corrected oil immersion condenser is required for high-power work. Any of the standard illuminants may be used. The author prefers the blue band of the magnesium spark spectrum to any one of the others. This source of illumination is convenient, easily centered, does away with the necessity of filter screens, and the light is monochromatic and sufficiently intense to take photomicrographs at 1,500 diameters with 30-second exposures. Medium speed plates should be used giving neither great nor slight contrast.

The remainder of the apparatus will include the usual paraphernalia found in any microscopist's laboratory, such as turntables, slides, cover glasses, brunswick black, reagents, etc. A thickness gage should always be on hand in order to obtain correct cover glass thickness for the 4 mm. objective and proper thickness for the slides. The rubber investigator will require in addition a microtome capable of adjustment to 0.5 μ.

Mounting

It has been stated that "photomicrographs can be made and interpreted in all sorts of ways." This is quite true, but the pigment microscopist need not feel any apprehension concerning such a fact. It is very easy to decide whether a pigment photomicrograph is correctly made or not, and if not there is no reason why anyone should attempt to interpret it at the risk of arriving at a faulty conclusion. A properly made pigment photomicrograph can tell only a true story.

If we select almost any series of the published paint pigment photomicrographs and examine them critically, a number of instructive facts become apparent. The first is that there is nothing characteristic about any one of them serving to distinguish one pigment from another. Secondly, if we had no previous knowledge of the subject, it would be impossible to decide if the photomicrograph showed individual particles or not. Our natural conclusion would be that pigment photomicrographs are an excellent example of misdirected energy. In order to avoid such a conclusion, let us ascertain what faults exist that make work of this kind valueless and then determine the best means for correcting them.

Referring to Fig. 1, it is obvious that:

1. The illumination is neither critical nor properly centered.

2. Magnification and resolving power are both inadequate, being much too low.

3. The mount is not properly made. No attempt at dispersion.

With regard to No. 1, this fault exists so universally that it is the rule rather than the exception. Any textbook on the subject gives full explanation of how to avoid it.

The second fault can be attributed to the facts that, first, the cost of high-class objectives is often prohibitive for the small technical laboratory, and second, the untrained microscopist finds such lenses difficult to use. For the most satisfactory work with fine pigments a 2 mm. oil immersion objective is essential.

It is undoubtedly in the third fault where the beginner meets with the greatest trouble. It never occurs to him that the construction of the microscope is such that it is best adapted for the examination of *minute* objects, and, to within reasonable limits, the smaller the objects and the more completely dispersed they are the better suited they become for microscopical examination. As the result of this lack of information attempts are made to look at a great mass of material in which no effort has been taken to spread it out into sufficiently thin sections.

Various States of Subdivision

If we examine any pigment as it is taken from the package, it will be noticed, especially with the aid of a hand lens, that it is composed of small pellets which are soft and quite easily rubbed out between the fingers. (Fig. 2.) The size of these pellets is not necessarily dependent upon the nature of the material, and is in no way likely to influence the quality of the paint or rubber in which the pigment is ultimately used. In fact, these pellets are of no particular interest to the microscopist, but it has been necessary to mention them, for there are instances where technologists have taken such for individual particles. As a rule they are composed of many thousands of particles.

When these pellets are rubbed out on a glass slide in a liquid medium such as water, permitted to stand a few seconds and then examined under the microscope, it will be noticed that the particles have collected into

groups or flocculates. It is on account of this flocculating tendency that it is sometimes so difficult to obtain well-dispersed mounts of pigments.

So far we have recognized three states in which pigment particles will be found to exist—namely, dispersed, individual particles clearly shown; flocculated, individual particles seen only with difficulty; soft pellets, individual particles not discernible.

There is still another condition that has not been mentioned, and that is one which sometimes occurs in precipitates like lithopone. In materials of this type there can often be found small undispersable aggregates composed of a half dozen or more particles firmly cemented together. These aggregates differ materially from the pellets, being very much smaller, visible only at high magnification and function as individual particles.

It is necessary for the beginner to become acquainted with the dispersed state and the three states of aggregation so that he can recognize each one without effort or doubt as to what type it is. The next step is to learn how to make a properly dispersed mount suitable for photomicroscopy.

There are four essential qualities found in a properly made mount.

(1) Proper particle density.

(2) Correct proportion of the largest and smallest particles.

(3) Suitable dispersion.

(4) All particles in a single plane.

In other words, there should not be too many nor too few particles in the field of the microscope; the largest particles as well as the smallest should be present and not pushed off to one side; pellets should be completely rubbed out and flocculation prevented; and all particles should lie in the exact plane of the microscope slide. The instructions for accomplishing these results were first given by the author in the *Journal of the Franklin Institute*, November, 1921. A pigment mount, made in the manner there described, can be used not only for visual observation but, on account of the fact that the particles are cemented in a single plane and free from brownian motion, can be satisfactorily photographed at high magnification. This should be carried out with transmitted light.

Nothing is gained, and in fact a great deal lost, by attempting to employ dark ground illumination, or the ultra-microscope. In this latter case it is impossible to distinguish small aggregates from individual particles.

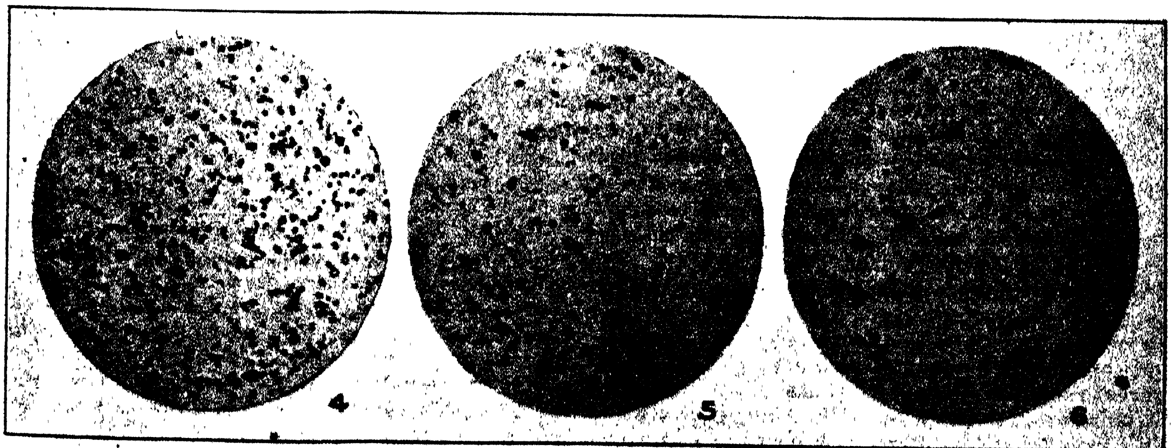
Photomicrographs of zinc oxide, lithopone, iron oxide, gas black, lamp black, sublimed white lead and corroded white lead should be made at 1,500 diameters, preferably with a 2 mm. apochromatic objective and a medium power compensating ocular. When moderate speed plates are used with a 5 ampere arc and a Wratten C filter about 1 or 2 seconds exposure is necessary, if the illumination is properly adjusted. With the blue band in the magnesium spark spectrum (as supplied with the Zeiss ultra-violet microscope) about 30 seconds is required for correct exposure.

The first requisite of a good pigment photomicrograph is that it shall unmistakably show the outlines of the ultimate particle. Preferably the particles should be separated and not touching or overlapping. When this is accomplished, all of the common pigments can be recognized and distinguished from one another without difficulty.

Characteristics of Common Pigments

Zinc Oxide. When this material is made by the so-called American process (Fig. 3), it yields its most characteristic forms. The single crystal particle is a hemimorphic hexagonal prism with acicular tendency. It readily forms twins, threelings and fourlings, all typically characteristic of this pigment. The particle size averages from 0.4 μ to 0.6 μ according to the method of manufacture. When made by the French process (Fig. 4), the particles are much less acicular and there seems to be no tendency for twinning; also the particle size is smaller, usually running from 0.3 μ to 0.4 μ on an average.

The addition of lead sulphate during the process of manufacture produces a solid solution with the zinc oxide causing the crystals to become short and thick. Fumed zinc oxide is always crystalline, though it is often erroneously referred to as amorphous. Microscopic examination of zinc oxide will show whether the material is a "straight" zinc oxide or a leaded one, and in the latter case will often indicate approximately how much lead is present. Furthermore, it can tell by what process the oxide was made and sometimes the type of furnace employed.

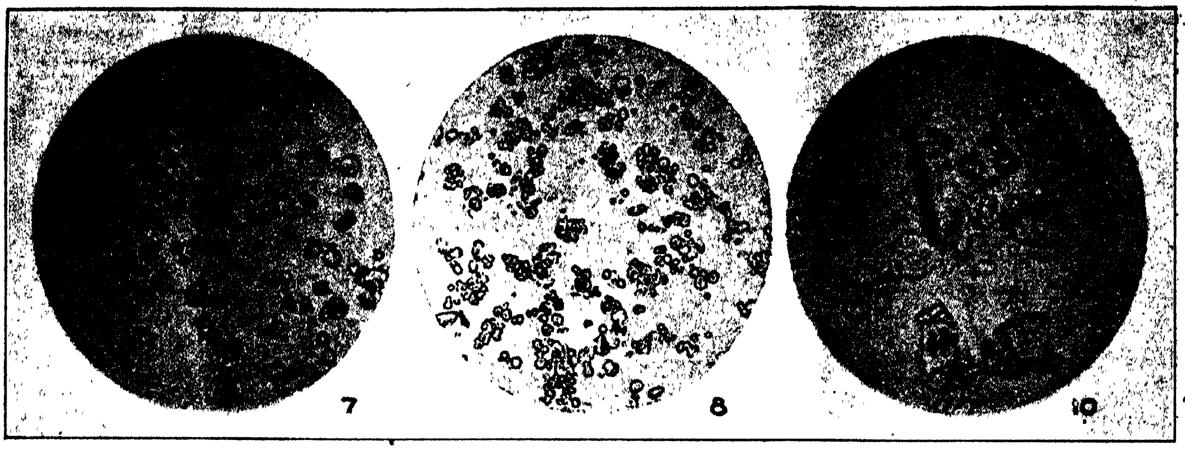


FIGS. 4, 5 AND 6

Fig. 4—French process zinc oxide, 1,500 diameters. There is less tendency here to form needles and twins than in the American process zinc oxide.

Fig. 5—Lithopone, 1,500 diameters. Note fine grain, different refractive indexes of particles and absence of any large particles.

Fig. 6—Lithopone, 1,500 diameters, taken with quartz lenses and ultra-violet light, showing clearly the transparent $BaSO_4$ as distinct from the opaque ZnS.



FIGS. 7, 8 AND 10

Fig. 7—Basic carbonate of white lead, 1,500 diameters, showing the characteristic hexagonal outlines of these crystals.

Fig. 8—Basic sulphate of white lead (sublimed white lead), 1,500 diameters. There is a slight tendency, not well shown in the photograph, for this pigment to form cubes.

Fig. 10—Barytes, 800 diameters.

Lithopone. Contrary to usual belief, lithopone is a fine-grain material, the average particle size falling between 0.3 μ and 0.4 μ. The misconception has arisen from the fact that lithopone rubs down in oil with a "pebbly" grain, but this should not be taken as an indication of the presence of large particles.

Under the microscope the material appears to be non-crystalline, the particles roundish in form, some having a high index of refraction and some low (Fig. 5). With the fluorescence microscope, sunproof lithopones appear dark, while the non-sunproof are beautifully fluorescent. Ultra-violet microphotographs show that these materials are composed of two ingredients, one transparent ($BaSO_4$) and the other opaque (ZnS) (Fig. 6).

Basic Carbonate of White Lead. On account of the large, well-defined hexagonal-shaped particles, this pigment is one of the best subjects with which to start in the study of pigment microscopy (Fig. 7). This material averages in particle size from 0.75 μ up to 2.0 μ and over, according to the method used in manufacturing it. When made by the Mathewson process, it is composed of large rough plates with a tendency toward the hexagonal outline.

White lead particles are never acicular, but always tabular. There are occasions, however, when this pigment contains elongated prisms of great size, but these are probably an impurity in the form of "normal" lead carbonate. Unlike zinc oxide, white lead is transparent to the ultra-violet wave length, 0.275 μ.

Basic Sulphate of White Lead (Sublimed White Lead). There is very little that is characteristic of this pigment. The particles are apparently non-crystalline, roundish in form, with here and there a tendency toward the cubical in form. The average particle size is about 0.65 μ (Fig. 8).

Gas Black. This substance is one of the most difficult subjects for microscopy (Fig. 9). This material can be successfully photographed only with the use of ultra-violet light. It is difficult for any one to see the gas black particle unless he possesses the trained eye of the microscopist. The individual particle does not look black, but slightly grayish or brownish, and seems to be more or less translucent. In size it is about 0.15 μ. Gas black has very strong tendencies to flocculate in all media and consequently it is not easy to obtain a well-dispersed mount of it. All gas black contains large lumps of undispersable material which are probably adamantine.

On the other hand, lamp black particles appear black under the microscope and are noticeably larger than those of gas black, about 0.3 μ to 0.4 μ. It is never possible to mistake one of these blacks for the other.

The Inerts. Barytes (Fig. 10), silica, asbestine and whiting (Fig. 11) are some of the principal inerts met with in paint and rubber. They are not difficult to recognize after the microscopist has become familiar with their characteristic features. In order to distinguish between barytes and silica it is sometimes a help to have on hand two liquid media of refractive indices of 1.54 and 1.64; silica is nearly invisible in the first

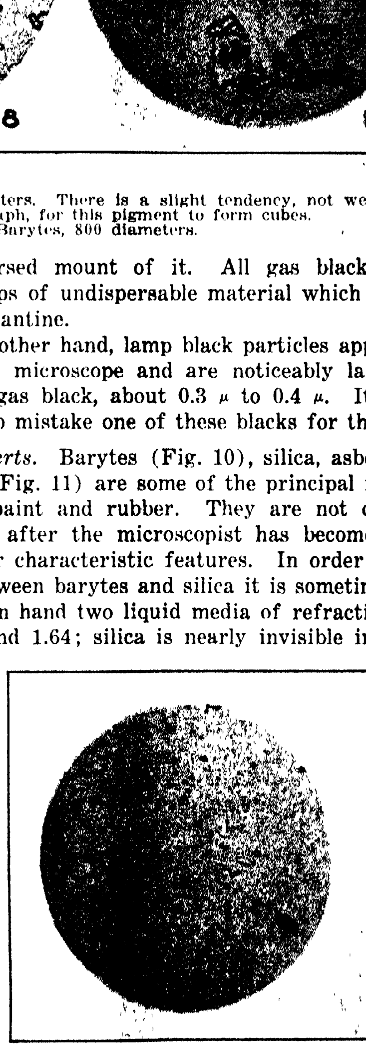


FIG. 9—GAS BLACK, 1,500 DIAMETERS
Taken with 1.7 mm. quartz monochromat and ultra-violet light.

and barytes in the second of these, giving an easy means for determining which material is being examined. Asbestine contains the characteristic rods of asbestos, though never so long as in the mineral itself. Whiting is easily recognized from the round "doughnut"-like shells of foraminifera which it contains.

The inerts possess such a low order of uniformity[2] that it is difficult to determine their particle size by the photomicrographic method, but as a rule they probably average from 5.0 μ to 10.0 μ in diameter.

[2] "A Photographic Method for the Determination of Particle Size of Paint and Rubber Pigments," by Henry Green, J. Frank. Inst., November, 1922.

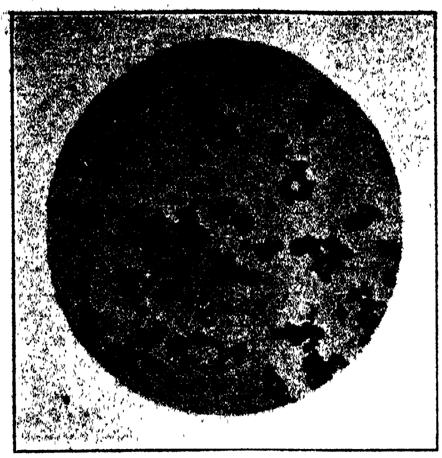

FIG. 11—WHITING, 500 DIAMETERS

Though the inerts are coarse in size, they are not "easy" subjects for the beginner, on account of their low index of refraction, making them difficult to see and impossible to photograph unless mounted in a medium of comparatively high refractive index.

Application to Research

When investigators finally become convinced of the fact that the ultimate working unit—the individual particle—can be seen and photographed through the microscope, then it should not be long before ways are found to apply the science of pigment microscopy to research problems.

The particle size of pigments is of the greatest importance to both the paint and rubber industries. In paint, particle size influences hiding power and consistency; in rubber, the resistance offered to abrasion. In order that as much guesswork as possible be eliminated from the estimation of particle size by the use of the microscope a method has been developed for the accurate measurement of pigment particles from negatives taken at a carefully ascertained magnification.[3] Prior to this research very little information as to the relative sizes of the common pigments was available. Investigators had made rough estimates of these for themselves, but they were admittedly only approximations and as a rule usually ran from 100 to 500 per cent too high. On the other hand, concerns manufacturing materials claimed to be colloidal often underestimate the particle size of their products to an even greater extent. Knowledge of proper methods for mounting pigments and the ability to use high-power lenses would soon correct these unnecessary misconceptions and pave the way for important advances in pigment technology.

Flocculation of Pigments

Perhaps one of the most important properties of pigments when incorporated in either rubber or paint vehicles, and one completely ignored until recently,[3] is that of flocculation. This property—or more correctly, the force which causes it—gives rise to the plastic nature of paints[4] and to the "stiffness" of compounded rubber. So far no microscopic method has been devised capable of giving more than a rough estimation of the magnitude of this force, but simple microscopic observation will always reveal its presence or comparative absence. In order to see it well in paints the material should be thinned with some of its own vehicle. This property depends entirely on the degree of wetting between the dispersed and continuous phases.

Flocculation of the pigment filler takes place in rubber, probably when its mobility is at its highest—that is, during vulcanization; the flocculates, having once formed, became permanent and can be studied in microsections made from the finished product. Rubber, of course, is plastic; consequently even when its mobility is high it still retains a yield value which, if greater than the force of flocculation of the filler, will tend to prevent the pigment particles from grouping. This is the case when rubber is compounded with zinc oxide. Here the wetting is of a comparatively high order, the flocculating tendency is weak, and the result is that microsections show very complete dispersion of this pigment in rubber.

The degree of wetting of the blacks by rubber is evidently low, for microsections show these pigments decidedly flocculated. It should be mentioned in this connection that poor incorporation of gas black will show as dense black lumps and should never be confused with flocculation, an entirely different phenomenon. Rubber microsections are made by first hardening the sample in a carbon tetrachloride solution of sulphur chloride,[5] or in melted sulphur,[6] or liquid air.[7] Sections are made from 0.5 μ to 5.0 μ in thickness according to the kind and quantity of pigment incorporated. Valuable information can sometimes be obtained from microscopic examination of stretched sheets of rubber instead of sections.[8]

Conclusion

Only three of the possible uses of pigment microscopy have been touched upon in this paper—namely, pigment identification, particle size measurement and the study of pigment flocculation. It requires very little imagination to visualize the innumerable problems which usually crop up during the course of a year's research on pigments, a large portion of which could be solved by the use of a knowledge of pigment microscopy. It has not been the intention, as stated earlier, to emphasize the application of this work to paint and rubber so much as to lay down the elementary principles upon which to erect a new science—the science of the microscopy of paint and rubber pigments, and as such, it is hoped, this endeavor will be found useful.

F. G. Breyer was, in all probability, the first investigator successfully to use the microscope in the study of zinc oxide. He recognized the crystalline nature of this material, which was supposed to be amorphous, and clearly distinguished between oxides made by different processes. At his suggestion the work, briefly given in this paper, was commenced about 6 years ago, and during that time has constantly received the benefit of his encouragement and enthusiasm, for which the author gives grateful acknowledgment.

German Brown Coal Compared With American Lignite

Is Almost Two-thirds Water, Ours One-third; Has 2½ to 13 Per Cent Agglutinating Matter, Ours Less Than 1½ Per Cent

BY O. P. HOOD
Chief Mechanical Engineer, U. S. Bureau of Mines

ALTHOUGH I had read many reports about the brown-coal industry of Germany, actual inspection gave me several impressions for which I was not prepared. We had fallen into the careless habit of thinking about German brown coal and American lignite as similar material. The great briquetting industry which has been built upon German brown coal has been frequently pointed to as an example of what we should do with our own lignites. This puts one in a frame of mind to expect a greater similarity in raw material than actually exists.

Analyses of the two materials indicate a great difference in water content. Our lignite has approximately 35 per cent moisture, whereas German brown coal in the Cologne district has about 60 per cent. Along with this difference in the moisture content is a considerable difference in physical character. Brown coal is much more like earth than like rock. It is far less consolidated than our lignites. We would not think of trying to force a spade into a bed of our lignite, but this would be quite possible with much of the German brown coal.

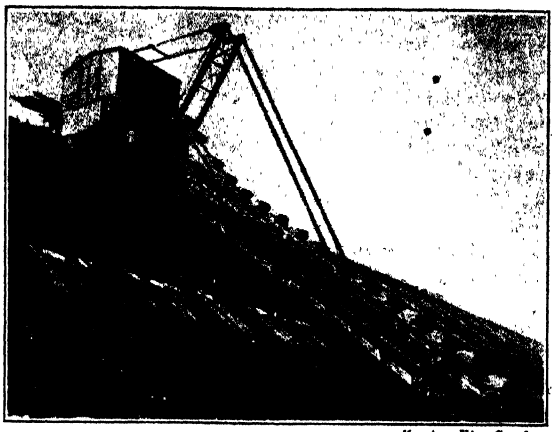
PHYSICAL CHARACTERISTICS

A piece of brown coal slightly consolidated and 3 in. thick is readily broken with the fingers like a piece of corn bread. Throughout a mass of brown coal small pieces of wood are much in evidence. The binding material between the annual layers of wood growth has almost disappeared, leaving the thin chips to curl and crumble when exposed to the sun. One small pile of brown coal exposed to the weather for a couple of months had the appearance of a chip pile.

These woody pieces had turned a dark chocolate brown, and they have various degrees of friability. Occasionally large chunks of wood are found that would offer considerable resistance to any digging device. The beds in various places vary in the proportion of fine and coarse material but in general the material is distinctly earthy. When taken to the briquetting plant the brown coal is passed over screens which take out pieces over about 3 in., and these are diverted to the boiler house for steam making.

The remaining material above ¼ in. is readily broken up in a disintegrator. Our own lignite would have to be put through rolls or a jaw crusher. The vegetable growth that furnished these great beds varied from time to time, so that in some places there is a distinctly banded appearance, the color varying from various shades of chocolate brown to a light yellowish brown. In mining by hand the material is easily dislodged with pick and shovel. Blasting seems unnecessary, and the excavating machinery scrapes it off a steeply inclined face.

Our own lignite, however, is consolidated, so as to be quite comparable in hardness with our more familiar bituminous coal. It is mined in the same manner as is soft coal, by the use of coal-cutting machines and explosives. It usually occurs, also, in measures that have rock above and below, whereas in the German



Keystone View Co., Inc.
CHAIN BUCKET CONVEYOR DIGGING BROWN COAL IN THE NIEDER LEUSITZ DISTRICT

measures the overburden is sand, gravel and clay. These differences are responsible for the different methods of working. The greater part of German brown coal is taken from open pits by machinery.

There is a limit, of course, to the depth of the overburden, as compared with the thickness of the coal, that can be economically removed, and when this limit is exceeded underground mining methods are used. Those parts of the beds that can be worked from open pits are developed first, but as the industry grows older the deeper lying portions will be worked by underground mining at a higher cost.

Our own lignite can in places be stripped of the overburden by excavating machinery, and can be loaded into cars by the same machines. This work probably would be done by our standard dipper excavators, and machines of this type are to a limited extent used in brown coal, but the relatively easy digging together with the uniformity of material has led the German engineers to develop in high degree the chain bucket excavator for this work.

CHEMICAL DIFFERENCES

Besides these physical differences there are important chemical contrasts. Certain materials in brown coal, on being heated, form an excellent binder and waterproofing material. The temperature at which this material develops is well below that of the distillation of any of the other coal substances. The percentage of this binder in the raw material must be at least 2½ per cent if briquets are to be produced by the German method. This method, briefly, is to subject the brown coal, which has been dried to a moisture content of about 13 per cent, to high pressure, pushing it through a converging die which generates sufficient heat by friction to melt the inherent binder and thus waterproof each particle. Different brown coal beds possess this natural binder in varying quantities up to 13 per cent.

The low-temperature distillation of this material yields lubricating greases and paraffine from which candles are made. Most of our American lignites have binding material of this sort in quantities less than 1½ per cent. This immediately suggests that our own problem of briquetting is fundamentally quite different from that of the German brown-coal area. We are quite justified in looking to the development of the brown-coal industry as an excellent example of what can be done when it is necessary to beneficiate a low-grade fuel, but we are not justified in looking to

this example for specific technical detail as a solution of our own lignite problem.

America has a lignite problem that must be solved in our own way to fit our own raw material and to suit our own economic conditions. The German brown coal occurs in well-populated districts where there is a high degree of industrial development coincident with a scarcity and relative high price of other fuels. It is in the possession, also, of a people who have not always had the choice of an abundance of the best coal and who have already acquired an attitude of thriftiness toward the use of heat.

Our own lignite occurs in districts furnishing a far less concentrated market and a much smaller degree of industrial development, and where the distances from coal field to a market are much greater. Our lignite also occurs among a people quite familiar with some of the best coals on earth and with habits of using heat in quantity, particularly for domestic purposes, quite unknown to European habit.

The brown coal industry of Germany at the present time is rapidly developing, as a result of the scarcity of industrial fuel. There is a real shortage of fuel which can be met in the most expeditious manner by the development of brown coal. While a relatively small percentage of Germany's total fuel resources are in the form of brown coal, they are turning to this portion for rapid development at this time. There is enough of this material to last from eighty to a hundred years, and the methods of mining and treating have been developing since about 1856, so that practices are substantially standardized and can be applied with little risk and uncertainty.

In 1921 the total output of brown coal was 123,000,000 tons, while more than 28,000,000 tons of briquets were produced. The raw brown coal is used for industrial purposes on step grates, but since it has only from 3,200 to 4,500 B.t.u. per pound, it is quite evident that it cannot be transported any great distance, except under extreme need. The briquets, on the other hand, make a most excellent fuel for industrial and domestic consumption.

It takes about three tons of brown coal to produce one ton of briquets, one ton of the raw material being required to reduce the remaining two tons to one of briquets. Their heat value is about 8,600 B.t.u. per lb.

Platinum in 1922

During the first 9 months of 1922 the imports of crude and unmanufactured platinum amounted to 72,410 oz., which is nearly 11,000 oz. more than the imports during the whole of 1921. Colombia supplied about half the crude platinum that reached the United States, and some Russian platinum came in through England and other countries. As the domestic supply of platinum and related metals is now almost completely dependent on imports, it is reasonable to expect a considerable increase in the quantity of new metals recovered by refiners. Stocks of platinum at the beginning of the year were about normal, amounting to 64,647 oz.

The large supply was reflected in the price of refined platinum, which throughout most of the year was from $87.50 to $90 an ounce but which early in the fall advanced to $108. Palladium remained at $55 to $60 an ounce without fluctuation. The price of iridium was fairly regular at $160 to $175 an ounce until fall, when a shortage of supply caused a considerable advance in price.

Oxidation-Reduction Indicators

Dr. William Mansfield Clark, chief chemist of the Hygienic Laboratory, spoke before the Chemical Society of Washington, Dec. 14, on "Oxidation-Reduction Indicators" and gave a demonstration of equipment used.

The speaker gave a brief description of the method used in the study of the oxidation-reduction equilibria among organic dyes. Titrations were carried out in a closed vessel under the protection of pure nitrogen. Electrode measurements were made against a saturated KCl calomel electrode and the single potential differences were reduced to the hydrogen scale. In all cases the dye solutions were buffered against change in hydrogen-ion concentration, as was also the titanous solution used for reduction.

It was shown that when the hydrogen-ion concentration was maintained rigidly constant the curves relating single potential differences to percentage reduction conformed to Peter's equation

$$E = E_0 - \frac{RT}{nF} \log_e \sqrt{\frac{reductant}{oxidant}}\,.$$

The value of n, as this is determined from the slope of the curve, is found to be 2 in the case of all dyes so far studied. The accuracy obtained by this method was as high as has been observed in the study of inorganic systems. The speaker particularly emphasized the necessity of controlling the hydrogen-ion concentration in measurements of this type and then pointed out the shift which occurs in the equilibrium potentials on change of acidity. Unlike most inorganic systems which require for their favorable study intense acidities or intense alkalinities, many of the organic systems may be swung through the whole gamut of acidity-alkalinity. When so handled they reveal the influence of hydrogen-ion concentration in details which have hitherto not been appreciated. To illustrate this the speaker showed his extensions of the data on ferrocyanide-ferricyanide mixtures and on the quinhydrone system. Carrying this into regions of p_H which have hitherto not been studied, it was shown that there is an orderly transition from regions where p_H has no influence upon electrode potentials to regions where the potential varies in an orderly manner with p_H.

There was then developed the mathematical treatment outlined in the speaker's book, "The Determination of Hydrogen Ions," 2nd edition, Chapter XVI. By means of the mathematical relations it was predicted from the chemical nature of certain of the dyes that the curve relating the potential at 50 per cent reduction to p_H should have at 30 deg. various slopes in various regions of p_H. By assigning arbitrary acidic and basic dissociation constants, equations were developed which fitted the experimental facts, and the constants so assigned agreed with independent estimations where these are available.

Taking as an example the substituted indophenols, the influence of substitution upon equilibrium potentials is revealed, and a new method of studying the influence of substitution is opened up. Substitution in any one type of dye was shown to have relatively little effect, a greater effect being found in the transition from one type of structure to another.

By selecting a series of dyes, the equilibrium potentials of which have been determined, it is possible to construct a system of oxidation-reduction indicators comparable in their own field with the acid-base indicators.

The Low-Temperature Carbonization of Coal

II—Results of Applying the Carbocoal Process to Various Types of Coal in Small-Scale Apparatus

BY HARRY A. CURTIS AND WALTER J. GELDARD

IN a previous paper[1] in this series the authors described the development of the Carbocoal process on a commercial scale at Irvington, N. J. In its final form this process consisted essentially of the three steps: first, carbonizing the coal at low temperature; second, grinding and briquetting the carbon residue, and third, carbonizing the briquets to render them smokeless. The Carbocoal process and the experimental plant at Irvington presently aroused a great deal of interest; inquiries began to come in from all parts of the United States, from England, France, Japan, Canada and elsewhere. Coal operators wanted to know whether their particular coals were suitable for making Carbocoal and what yields of byproducts could be obtained. In several cases carload lots of coal were shipped to Irvington, and tested in the commercial retorts, but the cost of such tests was high and it was difficult to measure accurately the byproduct yields from a few carloads of coal. To meet the situation there was finally developed at Irvington a complete miniature plant in which the various steps of the Carbocoal process could be carried out with 100-lb. batches of coal. In the following pages this small-scale apparatus is briefly described and the results obtained with several typical coals is discussed.

APPARATUS USED

Primary Carbonization—The low-temperature carbonization of the coal was carried out at 500 to 550 deg. C. in a cast-iron retort, shown in Fig. 1. This retort was mounted in a firebrick setting and heated by three surface combustion burners. In the early tests with this apparatus the paddle shaft was turned by hand, but later a motor drive was substituted. It will be noted in Fig. 1 that the retort is so designed that all the coal is within the heated area of the retort.

It was customary to carbonize three batches of coal of 33⅓ lb. each in this retort before disconnecting the byproduct apparatus. It would have been better to have had a larger retort and to have made a single charge of 100 lb.

Collection of Byproducts—The volatile matter distilled from the coal was passed successively through a condenser, a water scrubber, an exhauster, an acid scrubber and four wash-oil scrubbers, the residual gas passing to a holder. Arrangement of the apparatus is shown in Fig. 2. During the test, tap water was circulated through the condenser. One liter of water was placed in each water scrubber, 1 liter of 10 per cent H_2SO_4 in the acid scrubber, 1½ liters of wash-oil in each of the oil scrubbers. The wash-oil used was the ordinary high-boiling petroleum oil commonly used in byproduct coke plants. It was later shown by one of our co-workers[2] that, for the absorption of light oils from coal gas and for its subsequent analytical determination, absorbent charcoal is a much better, cleaner and more easily handled reagent. Accordingly, the four wash-oil scrubbers were removed and two tin tubes, in series, each containing 600 cc. of absorbent charcoal, were substituted. This change increased greatly the facility of setting up and handling the apparatus, as well as the accuracy of the analytical results.

During a run, tar and ammoniacal liquor collected in the condenser, the two water scrubbers, and a little in the sulphuric acid scrubber. The ammonia was distributed in the tar, the liquor, the water scrubbers and largely in the acid scrubber, while the light oil in the gas was removed by the wash-oil or charcoal scrubbers.

Briquetting—The carbon residue accumulated from the primary carbonization was ground to the proper screen in a small Hardinge ball mill, mixed with crushed pitch and then fluxed with live steam in a vertical fluxer. Briquets were made in a small Komarek press, the briquets being approximately the same size as made in the larger plant presses.

Secondary Carbonization—The briquets were carbonized at 1,000 to 1,100 deg. C. in a carborundum muffle 10 in. diameter by 36 in. length, the byproducts being collected just as during the primary carbonization of the coal.

DATA TAKEN DURING TEST

It is not possible in a brief paper to set down all the details of operating procedure with the small-scale apparatus described, nor to discuss all the precautions used in taking samples, in recording various measurements and in chemical analyses. It is perhaps worth while, however, to list below the items of information which each complete test yielded:

a. Proximate analysis, thermal value, ash fusing point, sulphur and nitrogen on coal tested.

b. Yield of gas, tar, ammonia and light oil during primary carbonization of coal and during secondary carbonization of the briquets.

c. Specific gravity and calorific value of primary gas and of secondary gas.

d. Specific gravity and distillation fractions for primary tar and secondary tar, with specific gravity and tar acid content of each fraction.

e. Yield of carbon residue and proximate analysis of same.

f. Screen analysis of carbon residue used in raw briquet mix, melting point of pitch used in same, and relative proportions of ingredients.

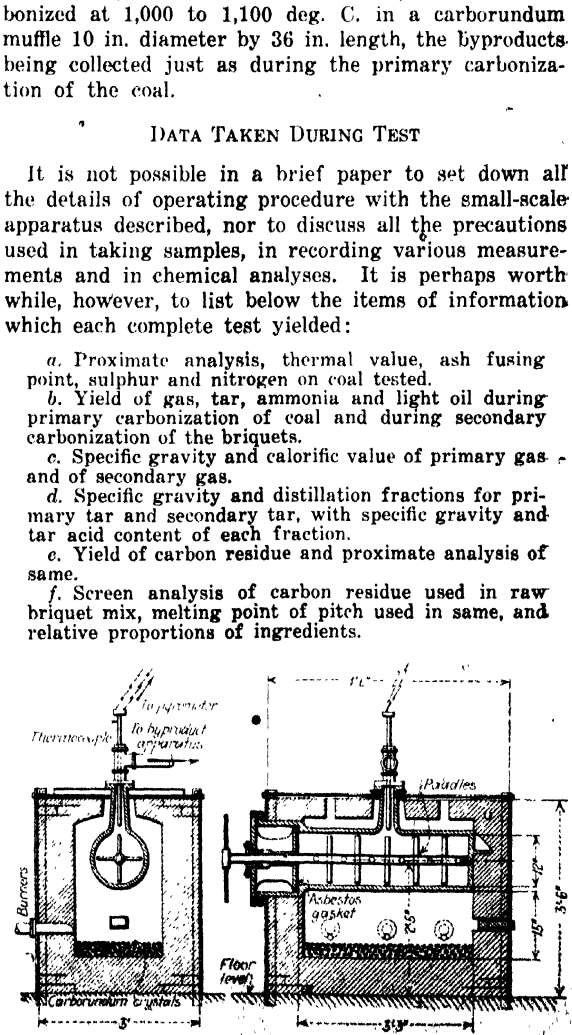


FIG. 1—SMALL-SCALE RETORT FOR LOW-TEMPERATURE CARBONIZATION

[1] Chem. & Met., vol. 28, No. 1, Jan. 3, 1923, p. 11.

[2] A. L. Davis. Data not yet published.

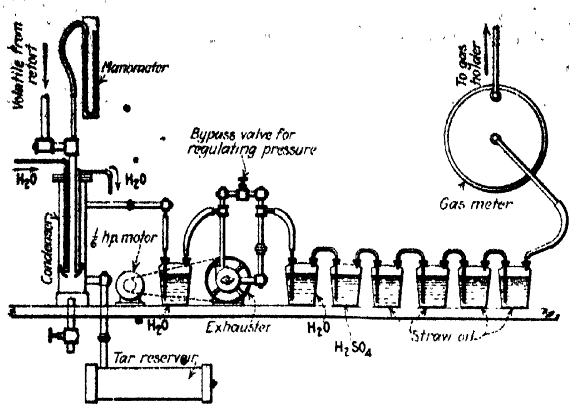

FIG. 2—APPARATUS FOR COLLECTING BYPRODUCTS DURING SMALL-SCALE TESTING OF COAL

g. Yield of Carbocoal and proximate analysis of same. Sulphur content, nitrogen content, calorific value, and usually a "drop test" of the Carbocoal.

The complete test of a coal in the small-scale plant described above came to be known in the company's records as the "Buffalo furnace test." There were something over 150 complete tests made at the laboratory at Irvington. It is not feasible to give the results of all these tests, but the attempt is made below to pick out various types of coals and summarize the data for these coals.

EXAMPLE 1. HIGH VOLATILE BITUMINOUS COAL

This particular coal was received as a carload shipment from the Russell mine of the Warner Collieries at Tiltonville, Ohio.

Item I—Proximate Analyses

	Coal As Rec'd	Coal Dry	Carbon Residue Dry	Carbocoal Dry
Moisture, per cent	4 5	......	......	......
Volatile, per cent	37 4	39.2	8 9	4.4
Fixed carbon, per cent	47 4	49 6	75 0	77.7
Ash, per cent	10 7	11.2	16.1	17.9

EXAMPLE 2. TEXAS LIGNITE

This particular sample of lignite was sent in by the Big Lump Lignite Co. from Rockdale, Tex. The results given below are of particular interest just now, since a plant is being built to carbonize and briquet this lignite.

Item I—Proximate Analyses

	Coal As Rec'd	Coal Dry	Carbon Residue	Carbocoal
Moisture, per cent	29.4			....
Volatile, per cent	32.7	46.3	13.2	7.7
Fixed carbon, per cent	30.1	42.7	69.3	74.2
Ash, per cent	7.8	11.0	17.5	18.1
	100	100	100	100
Sulphur, per cent		1.12	1	1
Nitrogen, per cent		1.45	1.5	
B.t.u.		12,155		10,541

Item II—Raw Briquet Data

Composition of raw briquet mix:

Lignite carbon residue	80
Powdered coal (coking coal)	10
Coke-oven pitch	10

The pitch from lignite is not suitable for binder if used alone, but can be used if it is blended with asphalt or with coke oven pitch

Item III—Yields per 2,000 lb. Dry Lignite Plus the Powdered Bituminous Coal and Extra Pitch Used in Raw Briquets

	Primary Carbonization	Secondary Carbonization	Total From Process
Carbon residue, lb.	1,143		......
Carbocoal, lb.			1,091
Dry tar, gal.	13.67	7.17	20.84
Ammonium sulphate, lb	11.75	6.70	18.45
Light oil from gas, gal			2.61
Gas, cu.ft.	6,475	4,651	11,126

Item IV—Gas Data

	Primary	Secondary	Total
B.t.u. of gas	603	291	473

EXAMPLE 3. MEDIUM VOLATILE, HIGH-ASH, BITUMINOUS COAL

This sample came from the Snowdown Colliery, near Dover, England.

Item I—Proximate Analyses

	Coal As Rec'd	Coal Dry Basis	Carbon Residue Dry Basis	Carbocoal Dry Bas
Moisture, per cent	2.3			.....
Volatile, per cent	24.6	25.2	7.6	4.5
Fixed carbon, per cent	55.8	57.1	68.4	72.2
Ash, per cent	17.3	17.7	24.0	23.3
	100	100	100	100
Sulphur, per cent		3.4		1.62
Nitrogen, per cent		1.9		
B.t.u.		12,462		11,358
Ash fusing point, deg. F			1,980 to 2,020	

Item II—Raw Briquet Data

Distribution of coal in process to primary retorts, 1,785 lb; to raw briquet mix, 215 lb.

Composition of raw briquets:

Carbon residue, per cent	78
Pitch, per cent	10
Powdered coal, per cent	12
	100

Item III—Yields per 2,000 lb Dry Coal

	Primary Carbonization	Secondary Carbonization	Total From Process
Carbon residue, lb	1,396	..	....
Carbocoal, lb.	..		1,505
Dry tar, gal.	16.3	7.5	23.8
Ammonium sulphate, lb	5.1	10.1	15.2
Light oil from gas, gal.	0.83	0.32	1.15
Gas, cu.ft.	2,552	5,019	7,571

Item IV—Gas Data

	Primary Gas	Secondary Gas	Total
B.t.u.	851	348	518
Sp.gr.	0.625	0.57	0.59

Item V—Tar Data

Sp.gr. of primary tar	1.062
Sp.gr. of secondary tar	1.181

Distillations not made.

EXAMPLE 4. MISCELLANEOUS COAL

In Table I there are given in less detail than in the foregoing examples the data obtained with a variety of coals. The table is meant to show only the general results from such coals and should not be used to draw conclusions by comparing the individual coals, since each test involved many details not mentioned in the table. It should be remembered that the results given in this table refer to the Carbocoal process complete and not to the low-temperature distillation alone.

Economic Status of Nitrogen Fixation in Germany

Present Production Still Inadequate to Meet Domestic Requirements—Recent Developments Compared With Pre-War Situation*

BY W. T. DAUGHERTY

Assistant Trade Commissioner, U. S. Bureau of Foreign and Domestic Commerce

THE importance of synthetic nitrogen for Germany's agriculture as well as for her industries is greater now than before the war. The present financial condition of that country prevents her purchasing Chilean and Norwegian nitrates in great quantity as she did in 1913. Furthermore, the necessity for increased domestic production of foodstuffs to free Germany from foreign supplies, for which she can ill afford to pay at present world-market prices, is now much more pronounced.

The result is a consistent effort to increase the fixation of nitrogen from the air—an effort which had its first real impetus when Germany went to war and was automatically cut off from importing Chilean nitrates. Germany's experience with nitrogen fixation has thus far been highly satisfactory, certainly from the standpoint of meeting the emergencies for explosive manufacture created by the war and the demands for the progressively intensive agriculture after the war. Although crop statistics for the past year, compared with 1921, would seem to belie an increase in the use of artificial nitrogen fertilizer, the real reason for the decrease in agricultural yields is probably to be sought elsewhere. German crops suffered from unfavorable weather this year and nitrogenous rehabilitation is still much needed to compensate for previous neglect resulting from the demands made by the ammunition industry on war-time artificial nitrogen production.

Germany's comparatively new synthetic nitrogen industry, as developed most efficiently by the inventions of Haber and Bosch, must be regarded as a very important scientific achievement, likely to compete in the world market of the future against native nitrate salts, as well as against the air-fixed products of Norway and Switzerland.

THE SUPPLY IN 1921-1922

German production in terms of nitrogen content in the fertilizer year[1] 1921-22 amounted to 300,000 tons, according to the most reliable estimate, while the needs of agriculture and industry are estimated at from 500,000 to 600,000 tons. Two-thirds of this production was credited to the two plants employing the Haber-Bosch process for the production of synthetic ammonia,

*Special report No. 35, dated Nov. 7, 1922, at Berlin, Germany.
[1]The German fertilizer year begins on May 1.

from which, with the aid of catalyzers, nitrate salts are produced. The nitrogen content of these salts is estimated at about 20 per cent, which indicates a production of 1,000,000 tons. One-sixth of the 1921-22 production of synthetic nitrogen in Germany is credited to the Frank-Caro process yielding calcium cyanamide (19 per cent N) for commerce, and an equal share belongs to the coke and gas factories, yielding ammonium sulphate (20 per cent N). The total production in 1921-22 was about 41 per cent above production in the previous year, and the ratio of increase was more or less uniformly distributed among the three processes of manufacture.

According to official statistics, the consumption of fixed nitrogen by German agriculture alone was 300,000 tons natural organic, but this included other nitrogenous fertilizers not discussed here. The German industries—e.g., dyes, sulphuric acid, celluloid, meat preserving, etc.—are accustomed to use about one-fifth of Germany's nitrogen supply. Net imports of Chilean and Norwegian saltpeter during the 1922 fertilizer year amounted to 17,768 tons of salts, equivalent to about 2,500 tons of nitrogen, accordingly but a fraction of the needs of the industry.

Pre-War Nitrogen Supply

Before the war, Germany imported more than half of her total supply of nitrogen. In 1913, her net imports of nitrates from Chile amounted to 746,811 tons of salts (containing roughly 120,000 tons of nitrogen) and from Norway, Switzerland and Sweden 48,141 tons of salts (containing roughly 6,000 tons of nitrogen). In this connection it must be remembered that the actual value of nitrates as plant food is somewhat greater than that of ammonium sulphate, although the latter contains a relatively higher percentage of pure nitrogen. The superiority of nitrates lies in the readier assimilation of their nitrogen by plant life. The ratio of their assimilation, as compared with that of ammonium sulphate, has been computed[2] as 100:98.

In the fertilizer year 1913-14 Germany produced about 110,000 tons of pure nitrogen from the operations of her coke and gas factories, about 5,000 tons by the Frank-Caro method, and about 7,000 tons by the Haber-Bosch process. The latter process was then in its infancy, while the former, now as then, is less economical, at least when dependent upon the power sources for electrical energy which Germany is able to offer.

Germany's gross supply of nitrogen for agriculture and industry in the calendar year 1913 (Note: The above production figures were for the "fertilizer year") was approximately 248,000 tons. Agriculture absorbed 210,000 tons of this amount, the remainder being used by industry. By similar computations, it is calculated that Germany's gross supply of nitrogen in 1912 was approximately 230,000 tons, with a similar ratio of consumption by agriculture and industry, and in 1911, about 185,000 tons.

It is interesting to note the increase in the use of synthetic nitrogen in Germany in the last 10 years. Besides having the poorest soil of any of the larger nations of Europe, Germany now has new difficulties in feeding her dense population, because of inability to buy abroad on a pre-war scale. Dr. Caro, head of the Bayerische Stickstoffwerke at Trostberg, which employs the process bearing his name (and also operated in America), has stated that if Germany's annual production of synthetic nitrogen is increased to 500,000 tons of nitrogen she can be freed from importing foreign grain. Others estimate that 600,000 tons would be required. It is assumed that Dr. Caro presupposes that German soil would also be adequately supplied with potash and phosphates, but even so his estimate seems very optimistic.

In connection with the general fertilizer situation, it is stated that German soil was overfed with phosphates before the war and that sufficient reserves are in the soil to allay any fears of an imminent phosphate shortage. The average ratio of nitrogen to phosphate and potash absorption by all German crops is estimated at 1 to ½ and 1 to 1½ respectively.[3]

The War Developments

The war revolutionized Germany's supply of nitrogen by building up a fixation industry. The process was by no means unknown when the war broke out. The arc process of producing nitric acid was already in use. Frank and Caro had discovered calcium cyanamide, and Haber and Bosch had perfected their process of producing ammonia by the direct combination of hydrogen and nitrogen.

It was the latter process that was destined to grow from small beginnings to the greatest single enterprise of its kind in the world. The Oppau plant, at Ludwigshaven-am-Rhein, operated by the Badische Anilin und Soda Fabrik, is now credited with an annual capacity for production of 100,000 tons of nitrogen; the Leunawerke at Merseburg with 200,000 tons. Probably only Germany's acute coal shortage and the explosion in the Oppau plant on Sept. 21, 1921, prevented capacity output in 1921-22.

The Situation in 1914

Germany had about 50,000 tons of combined nitrogen when she entered the war. Reserve stocks of Chilean nitrates contained about 25,000 tons; ammonium sulphate, about 20,000 tons, while about 5,000 tons was captured in Belgium, northern France and in the East during the first invasions. Relatively small amounts were imported from Norway and other neutrals. She was potentially able to produce 122,000 tons, 110,000 tons alone being from her byproducts coke and gas manufacture. The German steel industry, however, suffered a setback at the beginning of the war, so that this source of supply was diminished to about 65,000 tons in 1914-15. From her visible resources, Germany, then, was able to rely on 130,000 tons of nitrogen during the first year of the war. Her minimum requirement in 1914-15, it has been estimated, was between 200,000 tons and 220,000 tons to meet the needs of (1) the army and navy, for the manufacture of ammunition, (2) agriculture and (3) industry. The manner in which she developed her own resources in an endeavor to meet this demand affords one of the most interesting chapters in the history of science.[4]

It goes without saying, however, that the prior claims made on Germany's nitrogen supply by the ammunition industry during the war affected agriculture unfavorably, and that from the first year of the war German soil was progressively inadequately fertilized with nitrogen.

The main burden of responsibility for increased syn-

[2] "Stickstoffduengemittel," by Chemicker Dr. Harter, 1919. Fraenkische Ges. Druckerei, Wuerzburg.

[4] Discussed in "Die Stickstoffversorgung der Welt" by Walter Eucken, published in 1921 by "Deutsche Verlags-Anstalt," Stuttgart and Berlin.

thetic nitrogen production fell upon the two processes of Haber and Bosch and of Frank and Caro. The Oppau plant was already in operation, and it was immediately enlarged. The Leunawerke was erected in 1917 as an extension on the brown coal deposits in the Halle district, where cheap power was available. The Frank and Caro process was in operation at Trostberg, where the Bayerische Stickstoffwerke had its plants. Extensions for the emergency created by the war were created at Knapsack-bei-Köln; Gross Kayna, bei Halle; Waldshut; Piesteritz, and Chorzow, in Upper Silesia (since lost to Poland), all using the Frank and Caro process.

Production During the War

It was estimated that all of these plants working at capacity would be able to cover Germany's demand sufficiently to meet all exigencies. With the adoption of the Hindenburg military program in 1916, first estimates of Germany's need were far surpassed and production was, in consequence, always insufficient. It is interesting to note that the first year's estimated need of the army and navy, amounting to 50,000 tons, increased eventually, with the extension of military operations, to approximately 240,000 tons annually. Production lagged behind this estimate, the 1916-17 output being approximately 100,000 tons from coke and gas manufacture, 58,000 tons from Frank and Caro plants, and 64,000 tons from Haber and Bosch plants, or a total of 222,000 tons. This amount was increased in 1917-18 to a total of 271,000 tons, 100,000 tons being from coke and gas plants, 105,000 tons from Haber and Bosch plants, and 66,000 tons from Frank and Caro plants.

Future of the Industry

Production of fixed nitrogen in the fertilizer year 1922-23 will probably amount to 350,000 tons, or an increase of by 50,000 tons over the previous year. The main burden of production, as in the year past, will fall upon the Haber-Bosch process, which, as has been said, produced two-thirds of Germany's total output last year. While it is difficult to gage future competition of Haber-Bosch salts with natural nitrates, the costs of these salts on the inland markets are now much less than world market prices, so that for the present and immediate future the process represents a substantial economy.

That production costs can be kept down to the present level indefinitely is unlikely. All of Germany's synthetic nitrogen plants are located purposely on or alongside of natural sources of power, as for instance, the Leunawerke on the brown coal fields of the Halle District and the Trostberg works beside the swift current of the River Alz in Bavaria. Cheap and abundant power is a prerequisite for the development of the industry.

Calcium cyanamide manufacture, on the other hand, does not appear to have as promising a future. It depends upon the utilization of electrical energy, which is not as cheap in Germany as, for instance, in Norway and Switzerland. All in all, calcium cyanamide manufacture for fertilizer in Germany must be considered rather as an emergency enterprise made necessary by the war, and to a certain extent, as a less desirable but much-needed fertilizer during Germany's post-war reconstruction period, while she lacks ability to purchase the better nitrates on the world-market.

In order to cover the spread between an estimated 1922-23 inland production of about 350,000 tons of nitrogen and an estimated need of from 500,000 to 600,000 tons, Germany would have to import from 900,000 to 1,500,000 tons of 16 per cent nitrates in order to meet her maximum demand. Negotiations are reported to be in progress now among the government, agricultural interests and the trade to determine how far it will be possible to import "several hundred thousands of tons" of Chilean nitrates as a spring order for German soil. In case the government comes to the conclusion that it can make this investment, the trade has already promised to rush its order for spring fertilizing. If it were possible to do this, the claim is made that later Germany would not have to import any foreign grain, or at least only relatively small quantities, for the feeding of her population. All predictions of agricultural self-sufficiency, however favorable the fertilizer situation may become, must, however, be taken with great reserve.

Irrespective of any large purchases of Chilean nitrates that Germany may be obliged to make this year or next year, it is most probable that the former German market is permanently lost, and Chilean producers will doubtless seek a compensating market in the United States or elsewhere.

Manganese in 1922

Manganese ore containing 35 per cent or more of manganese shipped from domestic mines in 1922, according to figures compiled by the United States Geological Survey from reports of producers of manganese, amounted to about 13,500 gross tons, valued at $457,000. The ore of this grade shipped in 1921 amounted to 13,531 gross tons, valued at $495,097. The figures for 1922 represent the actual production for 11 months plus an estimate of the production in December. More than 10,000 tons of this ore was mined in Montana.

The new tariff act, which became effective Sept. 21, 1922, provides for a duty of $8 a ton on ore containing 40 per cent of manganese, $9 a ton on ore containing 45 per cent of manganese, $10 a ton on ore containing 50 per cent of manganese, and so on. Manganese should therefore bring an average price on the eastern seaboard amounting to the present average price of foreign ore plus about $9 a ton. The new tariff has not yet greatly affected the domestic manganese market, for even under its provisions not many domestic mines can be operated at a good profit; but the owners of mines that have heretofore been worked profitably have shown a renewal of interest in the industry, and some of the mines that are already developed and that yield ore of high grade will probably be reopened.

About 352,000 gross tons of ore containing 10 to 35 per cent of manganese, valued at about $1,232,000, was mined in 1922, as compared with 8,439 gross tons, valued at $42,755, in 1921. About 308,000 tons of ore of this grade shipped in 1922 was mined in Minnesota.

About 251,000 gross tons of ore containing 5 to 10 per cent of manganese, valued at about $630,000, was shipped from domestic mines in 1922, as compared with 62,670 gross tons, valued at $147,576, in 1921. About 248,000 tons of the ore of this grade shipped in 1922 was mined in Minnesota.

Up to Sept. 21, manganese ore amounting to 286,969 gross tons, valued at $2,824,989, had been imported into the United States in 1922, most of it from Brazil.

Cored Crystals and Metallic Compounds

Each Cored Dendrite Contains Many Small Crystals With Similar Lattices but Slightly Differing in Composition and Dimension—Intermetallic Compounds Usually Have Complex Lattices Giving Little Opportunity for Slip, Hence Are Brittle

BY EDGAR C. BAIN, M.Sc.
General Electric Co., Cleveland, Ohio

THE history of the solidification of binary alloys which form solid solutions over a range is such an important factor in their structure that it may be well first to review briefly the current views on what takes place when a melt of a single pure metal solidifies.

MECHANISM OF SOLIDIFICATION FROM MELT

When a metal is retained above its melting point, its atoms (or molecules composed of two or more like atoms) are isotropic, so far as is known. A melt cannot be said to possess directional properties. It is true that some bodies have been studied[1] which exhibit such slight rigidity that they could not be thought of as anything other than liquids, but which do have the anisotropic properties of crystalline bodies to a discernible extent. On the other hand, the glasses are not crystalline and are isotropic, but possess great rigidity; they must, therefore, be classed as liquids of enormous viscosity. If we omit these two exceptional types of substances, we have rigidity and anisotropy as the outstanding properties of solids.

Fortunately these two "borderland" types are not known in metals. When the liquid metal cools to its freezing temperature, the atoms become anisotropic. If two or more like atoms are associated as a molecule in the liquid, they separate before solidification and perhaps in so doing acquire directional properties. If these centers of newly acquired properties form within the melt with sufficient speed the whole mass becomes crystalline even during a very rapid fall in temperature such as a quench from the molten state. Metals act in this way. In a few "solid amorphous" bodies we know, such as silicate, these centers cannot form rapidly upon cooling. Lowered temperature brings on a molecular sluggishness or viscosity which prevents rearrangement of the atoms and the isotropy is retained when the mass is very rigid.

It is well to remember that the molecule loses its identity in the solid state. It may well be that in liquid NaCl one chlorine atom may be bound more or less permanently to a certain sodium atom and remain thus coupled except as some electromotive force causes a transfer, but in the solid state there is no assurance that any particular combination represents a molecule. In solid NaCl any one sodium atom has equal chances of pairing off with six different chlorine atoms all equally remote and nearer than any other atoms, as can be seen in Fig. 1.[2] Similarly, if we regard the beta brass range as depending upon the compound CuZn (as noted in the previous contribution[3] on "The Nature of Solid Substances," crystallizes in the body-centered cubic system), each copper atom has equal chances of combining with eight surrounding zinc atoms for a molecule of CuZn.

The number of nuclei which form in unit time in re-

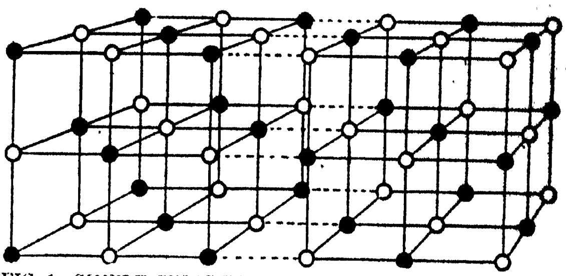

FIG. 1—SIMPLE CUBIC PATTERN OF SALT CRYSTAL (NaCl)

lation to the rate at which they grow determines the grain size. In metals the number of nuclei which form in a quenched specimen is so great that a very fine structure results when a melt is poured into cold water. Yet even here the whole mass is largely crystalline; X-rays are diffracted surprisingly well by even these tiny planes which form the three dimensional grating. It is quite likely, however, that the grain size may well be in the colloidal range.

On the other hand, the opposite extreme is possible. If a crucible of melted metal is maintained accurately just above its melting point, a single crystal touches the surface and provision is made for a slow conduction of heat so that the point of contact of liquid and solid is very slightly below the freezing point, no new nuclei form, but the crystal grows by addition of atoms from the melt. If now this single crystal be elevated and slowly removed from the melt at a carefully chosen rate, the crystal will grow at the same speed and a rod as long as desired can be produced with but one orientation present—it is a single crystal.

AMORPHOUS METAL

In the last analysis absolutely perfect crystallinity cannot be said to obtain in any piece of metal containing many polyhedral grains. Even when entirely pure there is some of the metal which does not have the regular atomic spacing of the normal crystalline body. This portion lies in the grain boundaries. It is commonly spoken of as amorphous metal. This expression probably describes quite well the condition of the thin zone of metal at the common boundary of two grains. When we consider that an atom retains its position in a space-lattice not alone by its own properties but by the established directional forces of all its neighbors, we are forced to postulate a zone of compromise existing between grains of unlike orientation. A "space-lattice distortion gradient" is formed between the two grains, and since the atoms are not in the normal relation to one another, then the arrangement is in many respects amorphous, although caused by and following definite force relations. This strained condition of the interatomic balance alters its electrochemical properties. Indeed, it is quite likely that the surface of any crystal has an altered structure to a depth of several atom rows or layers, since it is the common boundary of two unlike media. The author believes that the depth of the distortion zone—or in effect, the width of a grain

Chem. & Met., Jan. 25, 1922.

boundary—is a function of the *absolute* elastic limit of the material. In squeezing and pulling apart the atoms, so as to change gradually from one orientation to another, no single atomic spacing can exceed a limiting value; therefore a space sufficient for the purpose must be used up. Possibly in no case is it necessary to use more than a few hundred atom rows for this zone of readjustment, and perhaps much fewer for two grains whose orientations are not greatly different.

Solidification of Binary Alloys

When a melt of two mutually soluble metals is permitted to cool to the freezing point, we find the atoms arranging themselves in a space lattice starting from many nuclei, exactly as does a pure metal. In this space lattice we find both kinds of atoms. But a complication arises. The first crystallites are richer in the higher melting metal than is the melt. This well-known behavior is depicted in the constitution diagram by liquidus and solidus lines. It should be remembered that these lines represent only the equilibrium condition: if considerable time is allowed for cooling the first precipitated solid metal constantly changes its constitution by diffusion and grows richer in the metal of lower melting point until, when the last trace of liquid (now very rich in the lower melting metal) is solidified, the solid is uniformly of the original composition of the melt.

But it is very difficult to get such a condition except with extremely slow cooling. Actually the first deposited crystallites of dendritic structure cannot diffuse out their excess of higher-melting metal rapidly enough to maintain homogeneity with successive additions of new composition. Hence, the composition of the diminishing liquid phase grows inordinately richer and richer in the low-melting element and accordingly aggravates the disparity in composition of successive layers of deposited solid. (An alloy whose composition corresponds to a minimum in a solid solution, where the liquidus and the solidus are tangent, solidifies precisely as a pure metal and the phenomenon of coring does not occur.)

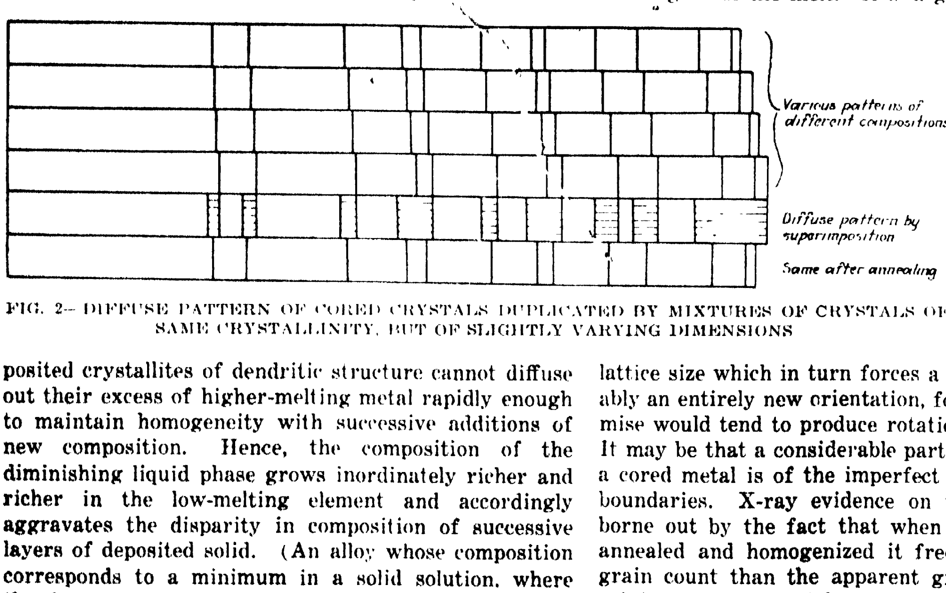

FIG. 2—DIFFUSE PATTERN OF CORED CRYSTALS DUPLICATED BY MIXTURES OF CRYSTALS OF SAME CRYSTALLINITY, BUT OF SLIGHTLY VARYING DIMENSIONS

In a cast metal exhibiting marked coring we discover usually a very comprehensive network of the first solidified material. This is a result of the directional tendency of grain growth: long spars of the crystals shoot out into the melt. The interstices fill in later. This effect can often be observed on the surface of metals which shrink greatly upon solidification—the first network formed is left high above the surface last to freeze.

The fundamental or primary grains of such cored structures are quite easily seen by etching—the boundaries either appear as dark lines, or there is an abrupt change in the orientation of the rectilinear streaks of the differently etched compositions. Frequently there is a very sharp demarcation of the coring, almost as if an abrupt change of chemical composition occurred or a new phase appeared. The action of chemical reagents on solid solutions varies quite rapidly with change in composition in the metal, so that no new phase need fill in the interstices between the primary dendrites to cause this appearance.

But when these large-cored grains are examined by the X-ray spectrometer, we do not obtain the characteristic spotted patterns of large grains, but the well-demarked spectrogram of smaller grains,[4] further modified by what must be a mixture of space lattices of various sizes. The patterns are identical with those which would be obtained from the fine mixed powders of a number of various alloys covering a broad range in a binary solid solution series. The first few diffraction lines are somewhat sharp, but become broader and more diffuse until at 30 or 40 deg. they are entirely lost. Such a cored alloy after prolonged heating near the melting point gives a normal pattern. Fig. 2 shows how the assortment of sizes of the same atomic arrangement produces, by superimposition, the diffuse, faint pattern. When the mechanism of coring is analyzed we come to the conclusion that the resultant alloys are actually an assortment of many crystals of varied spacings. The apparent grain boundaries inclose several orientations.

Let us consider a primary dendrite or crystallite just forming from the melt. It is a grain composed of two kinds of atoms. This grain can grow only so long as the added atoms can conform to the original lattice size or spacing within its elastic limit.[5] But its growth is inhibited. As shown in Fig. 3, the change in composition of subsequent layers forces a change in lattice size which in turn forces a new grain (and probably an entirely new orientation, for the zone of compromise would tend to produce rotation at some localities). It may be that a considerable part of the entire mass of a cored metal is of the imperfect crystallinity of grain boundaries. X-ray evidence on this point is further borne out by the fact that when badly cored metal is annealed and homogenized it frequently has a higher grain count than the apparent grain structure of the original cast material would indicate. This is very conclusive evidence, since grain growth occurs as they are permitted to attain equilibrium, except where allotropic changes interfere. The probable mechanism of this action is that two or more regions within the cored grain become grain-growth centers and are differently oriented even after diffusion has made them the same compositions.

Many of the alloys studied by the writer were made by mixing very fine powders and then heating to a temperature which would permit complete diffusion and homogenization entirely in the solid. It is possible in

[4] See "X-Ray Data on Martensite Formed Spontaneously From Austenite," by Edgar C. Bain, *Chem. & Met.*, March 22, 1922, vol. 26, p. 542.

[5] Elastic limit is low at high temperature.

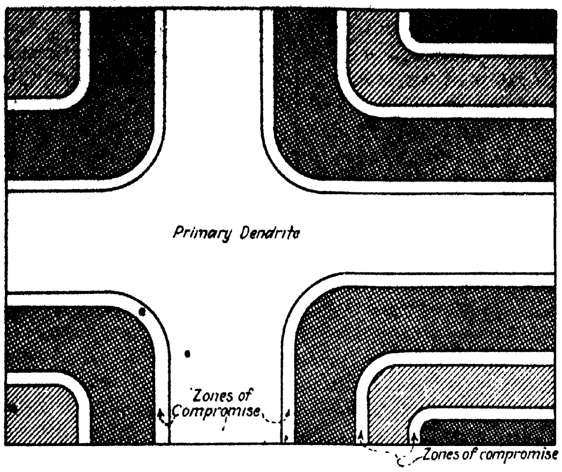

FIG. 3—THE PROBABLE STRUCTURE OF CORED METALS COMPOSED OF SHELLS OF DIFFERENT SIZED LATTICES

this manner to obtain perfectly uniform composition in less time than by melting the constituents and then destroying the cored structure resulting from the solidification. The aggregate paths of diffusion are shorter in fine powder than from zone to zone of the cored structure, for the latter is frequently coarse. Some mechanical deformation is most efficacious in removing cores. Fig. 4 shows the pattern of the mixed powders of gold and copper and after heating below the melting point.

The Ultimate Homogeneity in Solid Solutions

Obviously the most even and uniform distribution of two kinds of atoms in a space lattice is an arrangement of geometrical symmetry. For some atomic proportions this is quite simple. Let us consider an example. Fig. 5 is reproduced from the preceding contribution[5] which discussed the gold-copper series, and shows the arrangement for 3:1 and 1:3 atomic proportions in a face-centered cubic lattice. The 1:1 ratio in the body-centered arrangement or in the simple cubic pattern of rock salt (Fig. 1) is equally simple. For more complex ratios the geometrical arrangement is very much involved and may only be represented by groups of a certain ratio separated at frequent intervals by a leaner or richer zone.

The author has obtained conclusive evidence of the existence of such structures in a very few cases only. It comes about in this manner: The atoms of one metal alone may be considered as having their own space lattice. Thus, in a $25A:75B$ atomic proportion in the face-centered lattice shown in Fig. 5, the A atoms occupy a simple cubic lattice composed of the corners of the face-centered cubes. A little study will show that the B atoms occupy the corners of three equal systems of interpenetrating simple cubes.

Its pattern (Fig. 6) contains more lines than the face-centered lattice of both kinds of atoms. If these lines appear ever so weakly on a film, then there is ample proof of the arrangement. But to obtain such evidence there must be a difference in reflecting power in the atoms. Disparity in atomic weight is the usual cause. It should be remembered that it is the discontinuity in mass distribution which causes the lines on the patterns and excess mass is no more effective in causing interference minima (i.e., lines in the X-ray spectrogram) than the absence of matter.[6] In such simple geometric proportions as 3 to 1 or 1 to 1 we have the characteristic structure of compounds. Equal atomic proportions of molybdenum and tungsten (body-centered cubic system) show best the extra lines in the spectrogram which give us the clue to the atomic arrangement. Tungsten has almost twice the atomic weight of molybdenum and the spectral lines produced by the wide spaces between its planes alone cannot be "interfered out" by the weaker reflections of the molybdenum reflections 180 deg. out of phase. In the equal atomic ratio both molybdenum and tungsten atoms taken separately are in the simple cubic arrangement; the corners of one system are located in the center of the other.

There is another condition of the atoms in solid solutions offering a degree of homogeneity midway between this one of geometrical symmetry and the cored condition (which is similar to mixed powders of different composition). It is found in electroplate of two metals deposited out of solution simultaneously or in alloys which do not core and which have been cooled quickly from solidification. The space lattice is of uniform size and the atoms are of uniform concentration over a considerable area, but their arrangement is at random in the lattice. Neither kind of atoms considered alone could be said to possess a regular spacing. Prolonged heating near the melting point develops the final geometrical distribution.

Tammann has used a very expressive word for the rearrangement of the atoms which take place at high temperature. The word is "Platzwechsel"—place interchange. Its occurrence marks the temperature at which the mobility of the atom is such that it may migrate between and past its neighbors—one of these then taking its former position. In the new edition of his "Lehrbuch der Metallographie" a long chapter deals

[6]The X-ray method for crystalline analysis has been outlined by Bain in *Chem. & Met.*, Oct. 5, 1921, vol. 25, p. 657, and by Jeffries and Archer in *Chem. & Met.*, May 4, 1921, vol. 24, p. 771.

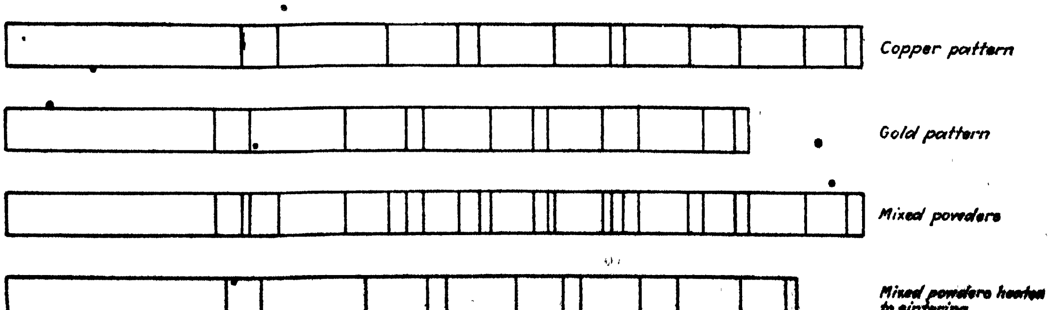

FIG. 4—PATTERN OF MIXED COPPER AND GOLD POWDERS, BEFORE AND AFTER SINTERING

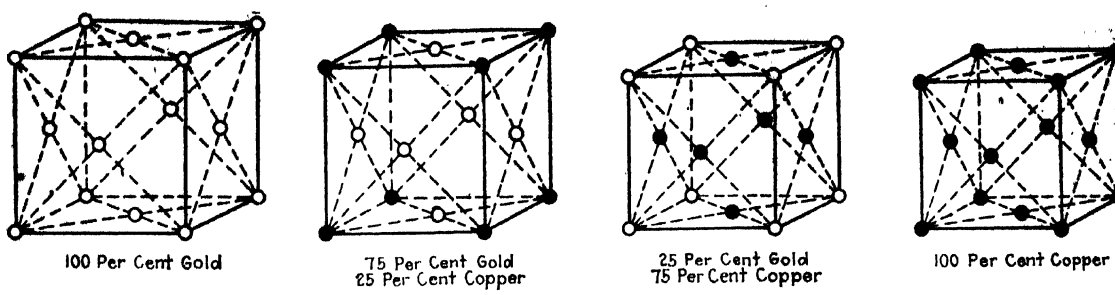

FIG. 5—ARRANGEMENT OF THE GOLD (LIGHT CIRCLES) ATOMS IN SPACE FOR CERTAIN GOLD-COPPER ALLOYS

with the change in chemical behavior observed when metals have been heated to bring about this final change in atomic distribution. In metals composed of two kinds of atoms which are not distributed with geometrical symmetry the change in single potential or chemical activity varies with change from one composition to another only as the theory of probability would indicate. The atoms of the nobler metal (i.e., with lower single potential) protect the other atoms to an extent dependent directly upon composition alone. But after "place interchange" has taken place, very abrupt changes in single potential with change in composition develop. These changes nearly always mark some simple atomic ratio. Thus: copper-gold alloys are rapidly attacked by nitric acid when there are fewer gold atoms than copper atoms in the alloy, but alloys richer in gold than 50 atomic per cent are attacked scarcely at all. The protective action begins abruptly at this definite composition. Therefore, there must be some subtle effect in the atomic distribution.

It appears that the situation is substantially one of availability of atoms for reaction. When the inactive atoms exceed a certain proportion and are arranged well-annealed alloys, while this chemical behavior is to be observed in almost any solid solution series. The author had, however, found the significant supernumerary lines in the spectrograms of certain alloys of simple atomic proportions before the publication of these chemical and electrochemical data. The failure to find the extra spectrogram lines significant of geometrical arrangement of two kinds of atoms in other instances is easily explained. They are necessarily always extremely weak. Furthermore, an exact ratio (say 1:3 or 1:1) can never be obtained in any alloy which has to be weighed out and prepared. Compounds could be prepared in which considerable fragments might conceivably have an exact ratio of atoms, even though the number of atoms reached "astronomical" figures. But, in a single grain of an alloy there will likely be a small excess of one or the other atoms. Somewhere, then, in the grain (fortunately perhaps at or near the boundary where the crystallinity is less perfect) we shall have a discontinuity. This discontinuity, if involving an even number of atom rows, will not destroy the extra spectrogram lines, but if involving an odd number completely obliterates the lines. The

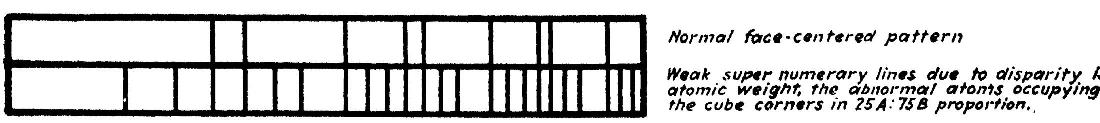

FIG 6—FACE-CENTERED PATTERN WITH SUPERPOSED LINES FROM SIMPLE CUBE

in the symmetrical positions for that particular proportion, there is no path for the reagent to penetrate the lattice and reach the active atoms. The protective action is then in effect. Below this proportion there are continuities of active atoms which can be reached successively after the surface lattice is caused to collapse. For a particular instance, consider the 75Au:25Cu lattice shown in Fig. 5. If that particular cube is located on the surface of the metal, it is seen that after the copper atoms on the corners of the top faces are removed, the next layer just below consists entirely of gold atoms.

Copper decomposes silver nitrate with the precipitation of metallic silver; gold does not possess this property. In the completely annealed series of copper and gold the alloys containing less than 1:7 Au:Cu decompose silver nitrate, while alloys richer in gold have no action with this reagent. If, however, the experiment is tried with a series of alloys which have not been heated long enough or at sufficiently high temperature to perfect this distribution, the reactivity simply falls off gradually with no definite limits.

As was stated, X-ray data give only limited information on the actual location of the separate atoms in result then becomes problematical indeed, and chance seems rarely to give us the evidence sought. At any rate the enlightening work of Tammann and his deductions from his observation—exactly in accord with what crystal analysis has shown in a small way—have given us an astounding conception of the forces which tend to produce the utmost homogeneity in metals by diffusion.

Intermetallic Compounds

Intermetallic compounds are said to possess no ductility. It seems that this condition is not a result of the chemical nature of the atomic association so much as it is the result of the circumstance that intermetallic compounds have lattice types which offer little opportunity for slip.[7] They have been investigated somewhat, and appear to possess low symmetry as a rule. As has been stated,[8] beta brass (if based on a compound) is an exception, for it is body-centered cubic in structure and has some ductility. Fused silver chloride might be said to possess some indications of ductility and the compound is one of strong chemical

[7]It is perhaps unnecessary to remark that when ductile metals are overstrained, they deform by intercrystalline slip.

nature in comparison to many of the intermetallic compounds. The silver atoms alone are arranged in a face-centered cubic structure, as are also the chlorine atoms alone, but both together form a simple cubic lattice. Fig. 1 shows the exactly similar lattice of NaCl. It is obvious that the like atoms, taken by themselves, build up face-centered lattices, interpenetrating. The compound Cu_3Sn is close packed hexagonal in type (like zinc).

The outstanding feature of the intermetallic compounds is their ability to retain the lattice form over a considerable change in constitution. We can scarcely conceive of any portion of sodium chloride or ferrous sulphide or calcium oxide as having any variation in composition from the "atom for atom" ratio, even though the compound is formed where one constituent is in great excess. On the other hand, we find sometimes that the crystalline structure of an intermetallic compound is formed with a composition which depends on the composition of the melt from which it is developed. In other words, in a compound which would normally contain say three atoms of A with one of B (A_3B), there is nothing to prevent the substitution of a few B atoms in the A lattice points. This ability to retain the crystalline phase intact despite a change in constitution probably is a result of the same fundamental structure within the atom which gives many metals their outstanding property of ductibility or malleability by slip-plane formation.

Lines of Attack on Future Problems

Of the array of interesting problems which may find a solution in the study of crystal structure there is one which is worthy of considerable investigation. It is the author's belief that in some cases a solid solution may form by the annexation of small atoms to large ones while these large atoms retain their usual lattice position. Thus, when carbon dissolves in gamma iron it is conceivable that the carbon atoms might associate with certain iron atoms—not displacing them, but simply "adding on." There is evidence on both sides of this question, and the facts will surely be discovered by X-ray examination. Experiments are now well under way in the author's laboratory to determine the point.

And again, austenite formed by the solution of carbon in gamma iron may be rapidly quenched to inhibit the carbide formation and grain growth but allow the allotropic change. The question then arises, "What is the relation between the carbon atom and the new alpha iron lattice comprising the tiny ferrite grains forming martensite?" It has been styled a solution of carbon in alpha iron—but the word "solution" is not well chosen, for there is only mechanical stability in martensite. The carbon is atomically dispersed, probably, in freshly quenched martensite, but at best it is only a "pseudo solid solution."

Such problems at present have little hope for solution except by some very subtle sort of examination involving the atoms themselves, such as by X-ray spectrometry.

Acknowledgments

The author desires gratefully to acknowledge the assistance of two of his co-workers in the investigation of the numerous alloys. To W. P. Sykes thanks are to be given for the preparation of a number of alloys from mixed powders and to A. B. Gladding thanks are due for the careful computation of several space lattices.

Increase in Science Department Students at Princeton

According to figures compiled by the registration department, Princeton University, Princeton, N. J., there has been a pronounced decline of interest in the classics in the last year, and a corresponding increase of interest in science. This change is illustrated by the number of students taking the courses in the two departments in 1921 and 1922. In the first-noted year there were 730 men in the university taking either Latin or Greek; at the present time this has decreased to 659; the increase of students in modern languages this year was from 1,249 to 1,459. In 1921 the number of men taking either chemistry, biology, physics or geology was 1,712, while at the present time the science department has 1,842 students. A library of industrial relations is being established at the institution under the direction of Prof. Robert F. Foerster, made possible through a donation of $60,000 by John D. Rockefeller, Jr., for this purpose.

Electron Emission From Heated Metals*

When metals are heated in high vacuum, electrons, or atoms of negative electricity, evaporate from their surfaces. If there is another electrode in the evacuated space which is given a positive charge, the electrons drift over to this electrode (anode) so that a current flows between the two electrodes. Dushman has recently derived an equation which should supersede the well-known Richardson equation, giving the relation between the electron current and the temperature of the cathode. The advantage of this new equation is that there is only one constant which we need to know for each different cathode material, instead of two constants which were necessary for the Richardson equation.

The electron emissions from a large number of different materials have recently been measured. The thoriated tungsten cathode gives a current at a temperature of 1,500 deg. C. absolute, which is about 130,000 times greater than that from ordinary tungsten. Measurements have also been made of cathode materials that have even much greater emissions.

In order to get all the current that a cathode is capable of giving, it is necessary to apply to the anode a high enough voltage to overcome what is known as the space charge effect. By putting in gases positive ions are formed in the space between the electrodes, and these neutralize the negative space charge and allow the current from the cathode to pass across the space with much lower anode-voltages. In other words, the effect of gases is to increase the current-carrying capacity of the two. Such an effect is used in the Tungar rectifier. Care must be taken what gas is used for the purpose, for many gases have the effect of poisoning the cathode, and cutting down its emission to a small value.

If very high voltages are used on the anode, so as to produce intense electric fields, it is possible to pull electrons out of the cathode. In fact, it is possible to pull electrons even out of cold cathodes—that is, cathodes at ordinary temperatures. The currents obtained this way from the cathode come from very minute areas, but in these areas the current density amounts to more than one hundred million amperes per square inch.

*Abstracted from a lecture by Dr. Irving Langmuir, Pittsburgh, Pa., Nov. 29, 1922.

Menace of Loosely Drawn Contracts

Much Litigation Caused by Inadequate Expression of Intention of the Parties—Examples of Court Decisions Under Varying Conditions

BY WELLINGTON GUSTIN
Member of the Chicago Bar

WHEN does a contract provide for the sale to fill a buyer's requirements over a given period and when does it provide for the sale of a seller's output? These are questions of real seriousness. When two contracting parties close a deal for an output of one's plant or factory over a given period, or for one's requirements for his plant, factory or business over a period they should take special precaution to see that the instrument called a contract embodying their agreement expresses their intention. For the intention of parties to a contract determines the construction a court will ultimately place upon it, and this intention will be gathered from the instrument itself where possible and ordinarily the parties will not be permitted to explain this intention. If the contract as written purports to be a complete contract, their outside testimony or evidence will not be heard to explain what this intention was and what the contract means. A reason for this rule is that the parties themselves dispute and their written expression must be looked to. Another rule is that the language used or employed by one will be construed most strongly against the user.

INTENTION MUST BE CLEARLY WRITTEN

In the ordinary case of dispute in these matters there is an agreement in the intention of the parties to the contract well known at the time of its execution. The error made by the parties is that their intention is not certainly and completely expressed in the writing to which they resort in order to embody their agreement. Herein is the mistake that results in most of the litigation over contracts for "outputs" and "seasonal requirements" and the like. Such contracts are of such supreme importance to a plant or industry that one should ordinarily be surprised to find difficulties and misunderstandings as to the meanings of the agreements with a resultant failure to keep engagements.

But one may wonder if a great portion of such disagreements over one's undertakings is not really an attempt to avoid a bad bargain. In some cases arising since the war it is certain that parties did enter into contracts which proved exceedingly fortunate for some and exceedingly unfortunate for the others. Some used maximum requirements under contracts where otherwise they would have used minimum requirements; others were fortunate in having no limit attached to their requirements. Similar conditions existed on all sides. Most of the parties adjusted inequalities. Some openly violated their agreements to furnish at specified prices, and sold to the highest bidders. The extraordinary times were responsible for extraordinary measures being taken between parties.

CONTRACT SHOULD EMBODY FULL INTENTION

Honesty in contract obligations does not concern us here, but as a matter of precaution and information, the many cases here cited should warn parties contracting in the future to embody their full intention and agreement in language that cannot be misinterpreted and misconstrued by others when nothing but the cold type or writing can be resorted to, as when it is made the basis for a court action or defense. And where contract obligations are sought to be avoided, whether honesty and honor in business undertakings enter in or not, the party who finds that the language of the contract expresses with certainty what he intended it should will be fortunate indeed, while if he has ignorantly or negligently and carelessly used language that does not express his intention he may be surprised to wake up in the hour of greatest need for certainty in his contract to find that he has a contract which cannot be enforced, or otherwise, with actual or contemplated profits wiped out.

In a case arising in 1900 in Illinois the court says: "The contract in question is for appellee's "requirements" in stove bolts from Dec. 14, 1898, to Jan. 1, 1901, and this means such amount of stove bolts as appellee should need in the regular course of its business and not what appellee might choose to require from appellant." Russell, Burdsall & Ward vs. Excelsior Stove & Manufacturing Co., 120 Ill., App. 23.

In this case the price of the bolts soared and the claimant's requirements not being satisfied by the seller, the buyer went out into the open market and bought the goods and the additional cost above the contract price to the buyer was charged to the seller.

CASE INVOLVING ENTIRE OUTPUT

In another case on "output" the Supreme Court of Illinois said that a contract whereby a cement company agrees to sell, and a sand company agrees to buy, the entire output of the cement company's plant for a year at a certain price per barrel is compiled with if all cement manufactured at the plant is shipped to the buyer.

And if the manufacturer has shipped to the buyer all the cement produced at the plant in question, the buyer has no right to refuse payment under the contract upon the ground that the manufacturer's delay in filling orders has caused a loss to the buyer, and upon the buyer's refusal to make payment the manufacturer may treat the contract as terminated, discontinue shipments and sue for the balance due on goods already delivered. Garden City Sand Co. vs. Wellington R. Burt, 237 Ill., 473.

In the above case the test of quality for the cement to be manufactured was the standard of the specifications of the American Society of Engineers. The court here held that if the buyer contended the quality of the product delivered was not up to the standard of the warranty the burden of proof rested upon the buyer to show that fact.

The buyer contended that it appeared from the contract and from extraneous facts and circumstances in evidence that the parties intended that the plant should be operated to its full capacity, and that the buyer should receive during the year what cement could reasonably be produced by the plant when run at its full capacity. The court said the contract did not so state and the court could not import into the contract a provision which the parties have omitted therefrom. "Ordinarily," it says, "a reference to what are called surrounding circumstances is allowed for the purpose of ascertaining the subject matter of a contract or for an explanation of the terms used—not for the purpose of adding a new and distinct understanding." And in another case, Knox vs. Lee, 12 Wall, 475, the court there said: "There is a well-recognized distinction be-

tween the expectation of the parties to a contract and the duty imposed by it. . . . Were it not so, the expectation of results would be always equivalent to a binding engagement that they should follow."

Questions of price and quantity are interesting in a case recently decided by the U. S. Circuit Court of Appeals and affirmed by the denial of a certiorari by the U. S. Supreme Court, 42 Sup. Ct. 586. Plaintiffs, Taylor, Lowenstein & Co., brought an action at law against the Louisville Soap Co. to recover damages for a breach of contract for the purchase of rosin, in which defendant filed a cross-petition to recover overpayments made by it.

The contract provided for the sale by plaintiffs to the soap company of a quantity of standard quality grades G, H and I rosin. The defendant's cross-petition was based upon its construction of this contract in reference to price, and sought to recover payments in excess of the contract price. Two questions were presented to the court: first, as to the quantity covered by the contract, second, as to the price to be paid.

In reference to quantity the contract provided: "Louisville Soap Co.'s requirements from April 1, 1918, to March 31, 1919, 20,000 round barrels minimum, 40,000 round barrels maximum. Should buyer's requirements be for more than the maximum amount stipulated herein, orders for such excess are to be submitted to seller. If seller cannot supply, buyer will be privileged to buy such excess elsewhere."

Under this contract the soap company ordered and received, within the year, 12,989 round barrels of rosin, for which it paid in full, and which amount constituted its entire requirements. Plaintiffs brought this action to recover damages for the failure of the soap company to take 7,011 round barrels, the difference between the amount they did actually order, receive and pay for, and the minimum amount of 20,000 round barrels specified in the contract.

Dispute as to "Requirement"

The soap company contended that this was a "requirement" contract and that the provision "20,000 round barrels minimum, 40,000 round barrels maximum" is a mere estimate of the amount of rosin it would require for the year, and that therefore it was not obliged to take any rosin in excess of its actual requirements.

In reference to the second question as to price, the contract reads: "to be 50c. per 280 lb. over the official closing Savannah, Ga., market on date order is received at Mobile, Ala. In the event of two closing prices, the average is to apply."

The soap company contended that this provision in which the price was to be determined by the official closing price of a board of trade, instead of a fixed, definite and certain contract price to be paid, regardless of the market price, was further evidence of the intentions of the parties that the actual requirements of the soap company was the dominant provision of the contract as to quantity.

Adversely, Taylor, Lowenstein & Co. claimed that the soap company was required by this contract to accept and pay for this minimum amount of 20,000 round barrels regardless of its requirements, and as many more barrels as they required for their factory; that the provision in regard to requirements applied only to the difference between the minimum 20,000 bbl. and the maximum 40,000 bbl., which maximum quantity the Taylor company obligated itself to furnish the soap company if the requirements would amount to so many barrels, and if the soap company's requirements exceeded the maximum amount, then it had the right to elect whether or not it would accept or reject any orders in excess thereof.

Specifications as to Maximum and Minimum Held to Be Dominant Measure of Quantity

The court said there appeared to be an irreconcilable conflict between the courts as cited by the opposing counsel in support of their respective claims. But the various cases show that each was decided in reference to the particular contract involved, or upon a consideration of the "obviously dominant measure of quantity" in each contract. In the present case the contract does not suggest that the minimum and maximum amounts named are merely estimates. On the contrary, from the substantial difference between these figures it appears that the parties intended that the requirements should control between these two amounts, but should be neither less than the minimum nor more than the maximum. And it is specifically provided that if the requirements should exceed the maximum quantity named, the seller should not be obligated to furnish the same, except at its option. This maximum is specifically set up the contract as the limit of the seller's liability to furnish, said the court. Therefore it is a definite controlling quantity and not a mere estimate. And it would seem absurd to say that the parties intended that the maximum should be the dominant measure of quantity as to the seller's obligation to furnish, but that the minimum should not be the dominant measure of quantity as to the buyer's obligation to take.

Now in the case of Taylor, Lowenstein & Co. vs. Louisville Soap Co., above mentioned, it was insisted upon the part of the soap company that if the minimum and maximum named in the contract should be held to be the measure of quantity to be furnished thereunder, it would take all the meaning out of the further provision of the contract in reference to the company's "requirements." The court says that, on the contrary, such a construction would give full force and effect to both these provisions in relation to quantity, for there is a large scope for the operation of the provision as to requirements between 20,000 and 40,000 round barrels. While on the other hand, if the company's requirements were to be construed as the absolute measure of quantity, then the provision as to minimum and maximum quantity would be meaningless. Hence the court concluded that this contract required the buyer to accept and pay for the minimum of 20,000 round barrels of rosin, and it likewise required the manufacturer to furnish this amount and any amount in excess thereof, up to the maximum of 40,000 bbl., limited in that respect only to the buyer's needs.

Price Clause Also Uncertain

In this instant case another interesting point of uncertainty in the contract is shown. This relates to the price to be paid from time to time for the product. Under the contract for rosin it was to be paid for at a stated price above the official closing Savannah, Ga., market, which was intended to be the official closing price posted by the Savannah Board of Trade. It appeared that under the rules of that Board of Trade the official price could be determined only from actual transactions between factors and buyers, and that dur-

ing the last 2 months of the contract period there were no sales on which the closing price could be based. On this point the court held that there was no closing price within the meaning of the contract, although during that period the committee did post the closing price as determined by the last sale.

And where the price of goods sold was to be determined by the official closing price of a board of trade on the day the order was received, and during the last part of the contract period there was no closing price in that market so that the contract price could not be determined, both parties were relieved of their obligations under the contract. (Here was uncertainty again in the contract.)

But where the buyer ordered and received some of the goods after there was no closing price, though the last price determined by actual sales was daily posted as the closing price, and the seller made no misrepresentations which would prevent the buyer from ascertaining the true facts in regard to the posted closing price, the payment for the goods in accordance with the posted price was an acceptance of such price and the buyer thereafter could not recover such or excess payments.

OTHER TYPICAL CASES

For the benefit of those who may contract "outputs" or "requirements" the following cases are cited briefly:

The Louisville Soap case is found to be identical in language to the contract involved in another case, the Diamond Alkali Co. against Aetna Explosives Co., 107 Atlantic Reports 711. Here the contract provides, in reference to the quantity, "Buyer's entire requirements during 1916; minimum quantity 180 tons per month and maximum 250 tons monthly." In this case the court held:

"The minimum and maximum quantities fixed in the contract were not merely probable estimates of the quantities which the appellant was to take . . . but were definitely fixed quantities which the appellant could demand and the appellee was required to deliver."

In the action brought by the Staver Carriage Co. against the Park Steel Co., 104 Federal Reports 200, on contract, the instrument provided as to quantity: "All the tire steel, of good and suitable quality, which will be used in buyer's works prior to Sept. 1, 1899, not to exceed 14,000 sets, nor to be less than 10,000 sets."

Here the court held that this was a valid and binding contract within the different amounts specified; that the seller was obligated to furnish at least the 10,000 sets and as many more up to 14,000 sets as was actually needed for use in the buyer's work prior to Sept. 1, 1899, citing National Co. vs. Keystone Manufacturing Co., 110 Ill., 427, also Stover vs. Park Steel.

In another suit, Budge vs. United Smelting Co., 104 Fed., 498, the contract required the seller to furnish "all the mining timbers required and used at buyer's mine, about 600 pieces of the larger dimensions and about 15,000 pieces of the smaller dimensions." Here the court held that this was a distinct promise to receive and pay for about 600 pieces of one kind of timber and 15,000 of another.

In still another case, Highlands Chemical Co. vs. Mathews, the contract required the seller to deliver to the buyer, if required by him, 10,000 carboys of oil of vitriol, the defendant to take at least 7,000 carboys during the same time. In this case it was held that the defendant was bound to take the minimum amount, whether he needed it or desired it for the purpose of his business or not; and the correlative obligation rested upon the seller to deliver any amount within the maximum fixed by the contract if the buyer's needs required the same. Here the minimum of 7,000 carboys and the maximum of 10,000 carboys are obviously the "dominant measure" of quantity.

In a U. S. Supreme Court case, Smoot vs. United States, 35 Supreme Court 540, the contract provided for 140,200 cu.yd., more or less, of filter sand, for a specific construction of twenty-nine filter beds. It appeared from the contract itself that the quantity mentioned therein was approximate only. It was insisted, however, by the United States that a letter written by the government engineer, subsequent to the contract, specifically fixed the quantity at 151,000 cu.yd. This, however, did not allow for shrinkage, and the actual requirements of the government were 179,231 cu.yd. The Supreme Court held that a letter from the engineer in charge of the construction, to a contractor, who had entered into a written contract with the United States to furnish material at a specified price, could not modify the original contract or constitute a new one; that under the terms of the original contract the amount named therein was clearly an approximate amount only; and that the needs of the government for this particular construction was the obviously dominant measure of the quantity to be furnished.

POINTS ON PROPER CONSTRUCTION OF CONTRACTS

Thus it will be seen, from these many cases cited, that much litigation occurs from lack of attention to the provisions of so important a class of contracts involving whole outputs of plants and all requirements for plants and industries. As was said in one of the cases: "Where the parties have entered into written engagements, with express stipulations, it is manifestly not desirable to extend them by implication. The presumption is that having expressed some, they have expressed all the conditions by which they intend to be bound under the instrument . . . and it is one thing for the court to effectuate the intention of the parties to the extent to which they may have even imperfectly expressed themselves, and another to add to the instrument all such convenants as upon full consideration the court may deem fitting for completing the intention of the parties, but which they, either purposely or unintentionally, have omitted." The former construes that which is written, "the latter adds to the obligation by which the parties have bound themselves, and is, of course, quite unauthorized, as well as liable to great practical injustice in the application."

Personnel Service for Technical Men

As a free clearing house for the promotion of research and its applications in industry, the Research Information Service is prepared to furnish critical information about modern personnel methods. Among the mechanisms especially designed for this informational service, there is maintained a personnel file in which consulting psychologists, personnel specialists and other reputable experts on problems of human adjustment are listed.

With specialists on these problems in the Council offices and with files of information at their disposal, engineers may profitably appeal to the Service for facts about methods of personnel classification. All communications should be addressed to Research Information Service, National Research Council, Washington, D. C.

Vapor Recompression System for Evaporators—II

Regenerative Evaporation Is Critically Discussed, With Particular Reference to the General Theory of Design and Construction—Comparison of Operating Economies With Single and Multiple Effect Evaporators—Bibliography of Patents and Literature References*

BY W. L. BADGER

Professor of Chemical Engineering, University of Michigan

General Theory

THERE have been a number of discussions of the general theory of vapor recompression. Of these the papers by Claassen (9, 15),† Flugel (18), Holmes (20), and Wirth (46) are the most important.[1]

Nozzles

The nozzle systems are perhaps the easiest to discuss qualitatively. From the curves of Figs. 9, 10 and 11‡, any case that is apt to arise may be calculated. It is evident that for high efficiency (in the sense of vapor compressed per pound high-pressure steam used) it is necessary to work with a small temperature drop and very high-pressure steam. From Fig. 9 it will be seen that to get double effect efficiency (1 lb. vapor entrained per pound high-pressure steam) the total temperature drop may not be over 18 deg. F. for 100 lb. steam, 22 deg. F. for 150 lb. steam, or 22.5 deg. F. for 175 lb. steam. Ordinarily evaporators are designed to operate with 5 to 15 lb. steam. If a single effect evaporator with a nozzle compressor be compared with a double working between 10 lb. and 26 in. vacuum, we find that the double has a total available temperature drop of 100 deg. F. against, say, 20 deg. for the other. Hence, on material of no elevation in boiling point, the double would have five times the capacity of the single, twice the heating surface, and would require the same amount of steam, condensing water and accessories.

On the other hand, if we assume that the plant has exhaust steam to spare, then the comparison is still more strongly in favor of the double. If a nozzle is used, either the power units must be run condensing, or exhaust must be wasted. If an ordinary double is used, it saves either all the high-pressure steam used in the nozzle (if exhaust was available which would otherwise be wasted) or it saves all the condensing equipment and condensing water otherwise needed for the prime movers.

The best use for the nozzle is the plant where all exhaust from prime movers is used in the evaporators and in addition make-up has to be supplied as live steam. A nozzle may be substituted for the usual reducing valve on the make-up steam line; provided, of course, that the evaporator in question is a multiple effect with a small enough temperature drop in the first effect to make the nozzle efficiency appreciable. Here again attention must be paid to the rapidly decreasing efficiency of the nozzle as the steam pressure drops; because if the amount of make-up needed is variable, the nozzle will give useful results only when the throttle valve is wide open. Under conditions demanding less than the maximum amount of make-up steam, its capacity will be negligible. This has been discussed by Claassen (9), who suggests several small nozzles in parallel to be cut in or out one at a time as the demand for make-up varies, but each to be either completely closed or wide open, never throttled.

Mechanical Compressors

Thermal Efficiency of Evaporators.—If the conditions are properly chosen and certain important considerations omitted, it is possible to show that vapor recompression systems are very desirable. For comparative purposes, let us assume that an ordinary evaporator uses steam at 5 lb. gage, and returns the condensate to the boilers at 180 deg. F. Then to regenerate 1 lb. of steam takes (1,155 — 180) or 975 B.t.u. Considering losses by radiation, heating feed, withdrawal of hot thick liquor, etc., let us assume that 1 lb. steam will evaporate 0.85 lb. water per effect. Then, for purposes of comparison, we will have as the performance of an ordinary evaporator:

Effects	B.t.u. Supplied in Boiler Per Lb. Evaporated
1	1,150
2	563
3	382
4	286

Let us also assume that the power used to drive the turbo-blower is generated in steam prime movers whose water rate is 20 lb. per kilowatt-hour. This rate, however, applies to steam of 160 lb. gage, which requires (1,195 — 100) or 1,095 B.t.u. to regenerate a pound. This assumes condensate returned to the boilers at 100 deg. F. because vapor recompression evaporators usually use a heat interchanger which cools the condensate and heats the feed. Ombeck's tests show 75 to 165 lb. evaporated per kilowatt-hour, or 3.5 to 8.25 lb. per pound boiler steam. This gives from 312 to 133 B.t.u. supplied in boilers per pound water evaporated. Wirth's data show 25 to 55 lb. evaporated per kilowatt-hour; or 875 to 400 B.t.u. per pound evaporated. Hence Ombeck's best tests correspond to 8.5 effect operation, and his poorest to 3.5 effect. Wirth's range from 1.5 effect to double effect efficiency. Such tests as Ombeck's and such reasoning as the first paragraphs of Article I are the basis for the claims so often made of "multiple effect efficiency in a single body."

It should be pointed out again that Ombeck's tests were run on that combination of conditions which is the most favorable to recompression. Wirth's data represent much more general cases. The efficiencies which have been calculated by advocates of thermocompression have not been confirmed by submitting operating data.

Capacity

The principal factors omitted by partisans of the thermocompressor are power generation and capacity of the evaporators. It is obvious that the turbo-blower must work on a small temperature drop. Thus Ombeck works with from 6 to 14 deg. F. Wirth gives no data but his evaporation per square foot per hour indicates

*Read before the American Institute of Chemical Engineers at Baltimore, Dec. 9, 1921. Part I of this article appeared in *Chem. & Met.*, vol. 28, No. 1, Jan. 3, 1923, p. 26.

†Numbers in parentheses refer to bibliography at end of this article. Numbers below 100 are articles and above 100 are patents.

‡See figures published in Part I.

[1]See also 1, [illegible].

a similar or larger temperature drop. Ombeck evaporates 1.7 lb. per square foot with 6.5 deg. drop and 3.9 lb. with 14 deg. Hence, assuming similar coefficients, Wirth must be working with 10 to 60 deg. drop. This explains Wirth's lower efficiency rating. Most discussions have been based on a drop of 18 deg. F.; and Soderlund and Boberg specify 5 deg. F.

Now ordinary evaporators usually run on about 100 deg. F. temperature drop. Hence if the discussion has to do with an ordinary evaporator in single effect, the thermocompressor evaporator must have from two to ten times the heating surface to do the same work if the coefficients are the same. The lower figure for heating surface corresponds to so large a temperature drop that it would involve less than double effect efficiency. In an ordinary single effect evaporator, the boiling point will be lowered corresponding to the vacuum. Hence there will be difficulty from increased viscosity, hydrostatic head, etc. The thermocompressor, working at atmospheric pressure, will have slightly better conditions so far as these factors are concerned. Ombeck's coefficients, the only ones so far reported, are no larger than are regularly obtained under good conditions in ordinary evaporators.

A double effect will have an average temperature drop of 50 deg. per effect. Hence if a thermocompressor could work with double effect efficiency on a 50 deg. drop with double the ordinary coefficients of heat transmission, it would do in one body all that an ordinary evaporator will do in two, both from the standpoint of thermal efficiency and of capacity. It would then remain to balance the cost of turbo-blower and driving unit on the one hand against the extra body of the evaporator and its condenser on the other. Similarly, the two methods are equal (except for difference in cost between the blower and the two bodies) if a thermocompressor could give triple effect efficiency on a 30 deg. drop with three times the ordinary coefficients. Wirth does not get triple effect efficiency in any case, and Ombeck gets it only on a 14 deg. drop. There is no evidence to support the assumption of higher coefficients in evaporators using recompression. Hence it may be definitely stated that a thermocompressor will call for much more expensive equipment than an ordinary evaporator.

Superheat.—Another factor which may affect the capacity of vapor recompression evaporators is superheat in the compressed steam. Pure adiabatic compression will necessarily result in some superheat. Turbo-blowers have a mechanical efficiency of 60 to 70 per cent according to size. This loss of 30 to 40 per cent of the power input should reappear as additional superheat in the compressed steam. Ombeck's blower had efficiencies from 45 to 68 per cent, but his results show superheat only a little greater than called for by adiabatic compression. This was probably due either to long pipe lines between blower and evaporator, with the measurements made near the evaporator; or to faulty measurements of the temperature of the steam. This is a very difficult determination to make with even moderate accuracy. The superheat on large working temperature drops may be over 100 deg. F.

The effect of superheat has never been settled because, even with large amounts of superheat, the heat present as superheat is small, and is transmitted in the first fraction of the heating surface. No tests have ever been made where an appreciable part of the heat available for evaporation was superheat.

It is generally supposed that the presence of superheat considerably lowers coefficients of heat transmission from steam to metal. This comes from the well-known fact that permanent gases give up their heat very slowly. The actual data available are entirely insignificant, and it is still an open question as to what effect superheat may have. If it has any effect, then evaporators using turbo-blowers must suffer greatly and cannot show normal coefficients of heat transmission.

In general, then, an evaporator using thermocompression will call for a larger investment in apparatus than an ordinary evaporator; and where it does not, it shows no special saving in steam.

Power Generation

Such a discussion as the above tells only half the story. No problem in evaporation should ever be discussed without including the question of power generation in the same plant. In the case above of the ordinary evaporators run on 5 lb. steam, the steam would in practice be exhausted from prime movers. Obviously, if the power demands of the plant are provided for and all exhaust used in existing equipment, adding a new evaporator would call for the generation of more steam and the comparison just made would need no modification. If exhaust steam were going to waste, the turbo-generator could not be considered, because the ordinary evaporator would run on exhaust, making no additional demands on the boilers. The thermocompressor would have to have high-pressure steam direct from the boilers.

Single Effect Operation

Consider a new department where both power and evaporation are to be provided and plans may be made for co-ordinating the two. The total amount of evaporation to be accomplished will call for a single effect only. In one case let us assume steam raised in the boilers at 160 lb. gage, expanded to 5 lb. in turbines, and sent to evaporators. The turbines generate power which can be used in the plant or sold. In the other case, let us assume 160 lb. steam raised in the boilers, part being used in condensing turbines to generate power equivalent to the power in the first case, and part used to operate evaporators. Let us base the comparison on 1 kw.-hr. under the first case, and consider that there is enough evaporation to be done to use all the exhaust there provided. The assumption made previously that 1 lb. steam to the first effect will evaporate 0.85 lb. of water per effect will still be made. The various possibilities are as follows:

Case *A*—1 kw. of power used, generated in non-condensing prime movers, exhaust to single effect evaporator operating on 100 deg. temperature drop.

Case *B*—1 kw. used, generated in condensing prime movers, additional steam used for single effect evaporator.
- (1) Steam raised at high pressure, expanded through reducing valve for an evaporator which is same as in Case *A*.
- (2) Same as (1), but expanded through a nozzle which compresses 1.2 lb. vapor per pound steam through an 18 deg. temperature drop.
- (3) The additional steam generates additional power in condensing prime movers, this power being used to drive a turbo-blower.
  - (*a*) Blower gives 70 to 80 lb. evaporation per kilowatt-hour on a 14 deg. temperature drop (Ombeck).
  - (*b*) Blower gives 40 lb. evaporation per kilowatt-hour on a 25 deg. temperature drop (Wirth).

A comparison based on 40 lb. boiler steam raised, would give:

	Case A	Case B (1)	(2)	(3a)	(3b)
High-pressure steam to be raised	40 lb.	20 lb. for power 20 lb. for evaporator	20 lb. for power 20 lb. for nozzle	20 lb. for power 20 lb. for blower turbine	20 lb. for power 20 lb. for blower turbine
Power units	1 kw. non-condensing turb-generator	1 kw. condensing turbo-generator	1 kw. condensing turbo-generator	2 kw. condensing turbo-generator, motor-driven blower	2 kw. condensing turbo-generator, motor-driven blower
5-lb. steam available for evaporators:					
Exhaust or expanded	40 lb.	20 lb.	20 lb.	None	None
Compressed	None	None	24 lb.	70-80 lb	40 lb.
Total	40 lb.	20 lb.	44 lb	70-80 lb	40 lb.
Total evaporation	34 lb.	17 lb.	37 lb.	60-68 lb.	34 lb.

A comparison based on 34 lb. of evaporation in all cases would give:

	Case A	Case B (1)	(2)	(3a)	(3b)
Total steam to be raised	40 lb.	60 lb	36 lb.	30 lb.	40 lb.
Water for condensers:					
Power condensers	None	500 lb.	500 lb.	750 lb.	1,000 lb.
Evaporator*	850 lb.	850 lb.	850 lb.	None	None
Total	850 lb.	1,350 lb	1,350 lb.	750 lb.	1,000 lb.
Heating surface of evaporators	x sq.ft.	x sq.ft	$3.7x$ sq.ft.	$4.8x$ sq.ft.	$2.7x$ sq.ft.

* In order to make a clearer picture, consider a case in which the total evaporation to be accomplished is 1,000 gal. per hour. On a conservative rating the evaporator in Case *A* should have about 350 sq.ft. The steam consumed in Case *A* will be 9,800 lb. per hour (0.85 lb. evaporation per lb. steam), which corresponds to about 250 kw. power for the plant. Based on the preceding table we shall have:

	Case A	Case B (1)	(2)	(3a)	(3b)
Total steam needed per hour	9,800 lb.	14,700 lb	8,800 lb.	7,400 lb.	9,800 lb.
Total water needed per hour	25,000 gal.	40,000 gal.	40,000 gal.	22,000 gal.	29,000 gal.
Heating surface	350 sq.ft.	350 sq.ft.	1,300 sq.ft.	1,700 sq.ft.	950 sq.ft.

Too many factors come in to make a hard and fast comparison of costs. The following table shows, very roughly, however, what may be expected in an average case. Overhead (interest, depreciation, repairs, etc.) is estimated at 20 per cent per year (300 working days). Labor is considered equal in all cases, and hence omitted. Steam is not brought into the cost, as its cost is too uncertain; but data for steam consumption have been given and steam cost may be inserted as desired. Water is taken at 5c. per 1,000 gal.

	Case A	Case B (1)	(2)	(3a)	(3b)
First cost:					
Evaporator and accessories	\$900	\$900	\$3,300	\$4,300	\$2,400
Power unit and accessories	8,500	9,500	8,500	19,000	19,000
Blower or nozzle	....	....	500	14,000	16,000
Total	\$9,400	\$10,400	\$12,300	\$37,300	\$37,400

	Case A	Case B (1)	(2)	(3a)	(3b)
Cost per day:					
Overhead	\$6.30	\$6.90	\$8.20	\$24.90	\$24.90
Water	30.00	48.00	48.00	26.40	34.80
	\$36.30	\$54.90	\$56.20	\$51.30	\$59.70
Excess cost over Case A exclusive of steam	......	18.60	19.90	15.00	23.40
Steam saved over Case A, tons per day	......	(Uses more than A)	12	29	0

Case *B*(3*a*) is the ideal case, and will seldom occur; but if the conditions here represented exist, and if steam costs over 50c. per ton, this calculation shows a saving. Actual operating conditions will come much nearer *B*(3*b*), and here there is no saving in steam and an increased cost of \$23.40 per day. In other words, in the case apt to occur in practice, the turbo-blower saves nothing in steam and may be much more expensive to operate than an ordinary evaporator. This reasoning leaves out of account the more expensive labor to operate the turbo-blower evaporators, differences in piping and distribution, etc. If the solution has an elevation of boiling point, the case against the thermo-compressor is still worse.

Multiple Effect Operation

Suppose the plant could not use 250 kw. of power, but that 80 kw. could be disposed of. This power, generated in a non-condensing prime mover, would give about 3,300 lb. exhaust per hour for Case *A*. This is about a third of that available in the previous illustration; but our 1,000 gal. of evaporation per hour could be now accomplished with this steam in triple effect. This case is rather abnormal, as the sizes of all equipment will come out small. Steam consumption and cost of equipment will be figured on the basis of commercially practical units, reduced to the conditions of the problem in proportion to the amounts handled (thus eliminating the excess costs of small units per unit capacity). The results will then be strictly comparable among themselves and with the case of single effect operation above. The triple used in Cases *A* and *B*(1) is to work with a 20 deg. temperature drop in the first effect, and evaporate equal amounts in each effect. The single (used in the other cases) is to work on the same coefficient as the first effect of the triple.

As before, case *B*(2) is a nozzle compressor with an 18 deg. drop, case *B*(3*a*) a turbo-blower on a 14 deg. drop, and case *B*(3*b*) a turbo-blower on a 25 deg. drop. The efficiencies are also the same as before.

MULTIPLE EFFECT OPERATION

	Case A Triple	Case B (1) Triple	(2) Single	(3a) Single	(3b) Single
Steam raised:					
Power	40 lb.	20 lb.	20 lb.	20 lb.	20 lb.
Evaporation		20 lb.	20 lb.	20 lb.	20 lb.
Power units and accessories	1 kw. non-condensing	1 kw. condensing	1 kw. condensing 1 nozzle	1 kw. condensing 1 kw. condensing and blower	1 kw. condensing 1 kw. condensing and blower
Steam for evaporation:					
Exhaust	40 lb.	20 lb.	20 lb.	None	None
Compressed	......	......	24 lb.	70–80	40
Total	40	20	44	70–80	40
Evaporation	135 lb.	68 lb.	37 lb.	60–67	34

135 LB. EVAPORATION AND 1 KW. POWER

	Case A	Case B (1)	(2)	(3a)	(3b)
Steam:					
Power	...	20	20	20	20
Evaporation	40	40	73	40–45	80
Total	40	60	93	60–65	100
H_2O for condensers:					
Power, lb.	...	500	500	500	500
Evaporation, lb.	850	850	3,400	1,000–1,100	2,000
Total	850	1,350	3,900	1,500–1.600	2,500
Heating surface	$3x$	$3x$	$3.3x$	$4.3x$	$2.4x$

Then for a total evaporation of 1,000 gal. per hour as discussed under single effect operation, we would have:

	Case A	Case B (1)	(2)	(3a)	(3b)
Total steam needed, lb. per hr. for					
Power	3,300	1,650	1,650	1,650	1,650
Evaporation	.....	3,300	6,000	3,500	6,800
Total	3,300	4,950	7,650	5,150	8,450
Total water used per hr., gal.	6,300	10,000	29,000	11,500	18,500
Total heating surface, sq.ft.	1,050	1,050	1,150	1,500	840

	Case A	Case B (1)	(2)	(3a)	(3b)
First Cost:					
Evaporators	$2,600	$2,600	$2,900	$3,800	$2,100
Power units	3,300	3,450	3,450	3,450	3,450
Blower or nozzle	.....	......	500	17,000	14,000
Total	$5,900	$6,050	$6,850	$24,250	$19,550
Operating costs per day:					
Fixed charges (20%) per yr., 300 days per year)	$3.90	$4 00	$4 60	$16.20	$13 00
Water at 5c. per 1,000 gal	7.50	12 00	34 80	13 80	22.20
	$11.40	$16 00	$39 40	$30 00	$35 20
Excess cost over Case A per day, exclusive of steam	.....	$4 60	$18 00	$17 60	$13 80
Excess steam used over Case A, tons per day	.....	20	56	22	62

Thus, on the assumption of power demands by the plant so large that exhaust enough is furnished to do all the evaporation in single effect, there is a possibility of so combining condensing power units and thermocompression evaporators to show a saving over the usual arrangement. This will be the case only when there is no scaling, no elevation of boiling point, no hot thick liquor withdrawn to the next step, etc. In the ordinary circumstances, thermocompression offers no saving as compared to a single effect, and will be still more expensive if compared to a multiple effect. In general, then, if the power demands of a plant are reasonably in proportion to its demands for steam for evaporation, thermocompression is out of the question except where there is some unusual special condition.

Plants Using Purchased Power

The above discussion is based on the idea that the plant generates its own power. In case the plant generates no power, and central station or hydro-electric power is available, the comparison is different if the price of purchased power is low. Even with moderately expensive power, if the factory has no steam plant and supplies all its power demands with purchased power, it might be more convenient to put in a turbo-blower than to put in a steam plant. On a strict cost basis, however, power would have to be available at a figure very much under the cost of generation in the plant to make the thermocompressor arrangement economical.

Plants With Small Power Demands

The case which is most favorable to the thermocompressor is that of a plant whose evaporation problems call for the use of very much more steam than can be supplied as exhaust from their power units. Here we have four possibilities (after all the exhaust from non-condensing power units has been used): (1) Raise additional low-pressure steam for ordinary evaporators, (2) raise additional high-pressure steam and reduce it for the evaporators with a reducing valve, (3) raise additional high-pressure steam and send it to a condensing turbine driving a turbo-blower, and (4) raise additional steam, send it to a non-condensing turbine driving a turbo-blower, and use the turbine exhaust (along with the compressed vapor) in the evaporator.

Case 1 is evidently out of the question, as it takes very little more heat to raise high-pressure steam than it would to raise 5 to 10 lb. steam. Further, the chance of future needs for high-pressure steam would in any case warrant the slightly greater first cost of the boiler plant designed for high pressures. Let us then assume that the non-condensing turbine takes 40 lb. per kilowatt-hour, the condensing turbine 20 lb., that the turbo-blower will evaporate (a) 70-80 lb. per kilowatt-hour and (b) 40 lb. and that 1 lb. of steam will evaporate 0.85 lb. of H_2O per effect. Let us assume also that the amount of evaporation is such that a triple or quadruple effect evaporator would be used if case 4 were adopted. Obviously then, in case 4 the first effect would be enlarged. The evaporator may be looked on as a combination of a triple run on exhaust steam and a single with a thermocompressor. The single and the first effect of the triple happen to be combined in one shell, but it is simpler to think of them separately. Let us base our comparison first on 40 lb. of boiler steam, which gives us the following figures:

	Case 2	Case 3	Case 4a	Case 4b
Steam raised, lb.	40	40	40	Same as 4a
Power units	None	2 kw. condensing turbine and blower	1 kw. non-condensing turbine and turbo-blower	Same as 4a
5 lb. steam available for evaporators—exhaust	40	None	40	40
Compressed	None	140–160	70–80	40
Total	40	140–160	110–120	80
Lb. evaporated in single (from compressor)	None	140–160	70–80	40
In triple (from exhaust)	102	None	102	102
Total	102	140–160	170–180	142
Evaporator bodies	3 of x sq.ft. each	1 of $4.5x$ sq.ft.	1 of $3x$, 2 of x sq.ft. each	1 of $2x$, 2 of x sq.ft. each
Total surface	$3x$	$4.5x$	$5x$	$4.2x$
Lb. evaporated per lb. steam	2.55	3 5–4	4 2–4.5	3.7
Condensing water Turbines, lb.	None	1,000	None	None
Evaps., lb.	850	None	850	850

If a quadruple be assumed in cases 2 and 4:

	Case 2	Case 3	Case 4a	Case 4b
Lb. evaporated By compressor	None	140–160	70–80	40
By evaporator	135	None	135	135
Total	135	140–160	205–215	175
Condensing water Turbines, lb.	None	1,000	None	None
Evaporators, lb.	850	None	850	850
Heating surface	$4x$	$4.5x$	$6x$	$5.2x$
Lb. evapd. per lb. steam	3.4	3.5-4	5.1-5.4	4.4

Assume an evaporator to remove 30,000 lb. of water per hour in quadruple effect. This would call for about 1,300 sq.ft. per effect, and a steam consumption of 9,000 lb. steam per hour. If the data from the preceding table be converted to equal amounts evaporated, we shall have:

	Case 2	Case 3	Case 4a	Case 4b
Steam, raised, lb. per hour	9,000	8,100	5,800	7,000
Water used, gal. per hour	23,000	24,500	14,500	17,500
Heating surface sq ft. total	4,200	4,200	4,200	4,200
Hp. of blower turbine	.....	250	150	125
First cost of evaporator	$10,500	$10,500	$10,500	$10,500
First cost of blower and motor	...	17,000	14,000	12,000
	$10,500	$27,500	$24,500	$22,500
Fixed charges per day (at 20 per cent, 300 working days)	$7.00	$18.30	$16.30	$15.00
Water at 5 cents per 1,000 gal	27.60	29.40	17.40	21.00
	$34 60	$47.70	$33.70	$36.00
Difference in cost from case 2 (excluding steam)	....	+13 10	—0.90	+1.40
Steam saved over case 2, tons per day	......	11	38	24

Hence, in the case where steam cannot be supplied to the evaporators as exhaust from power units, but must be furnished from the boilers, it may be most economically supplied through a turbo-blower driven by a non-condensing turbine. This is in line with the general principle that the most economical method of using steam to produce both power and evaporation is a non-condensing prime mover sending its exhaust to the evaporating device.

Bibliography

In the bibliography which follows every article to which a reference could be found is included, even though the original was not available. Some references were obtained from footnotes where the author did not cite his references accurately. This accounts for the incomplete citations in some cases.

Patents are arranged in numerical order except in the case of the English patents. These are arranged by years and numerically in each year. Where the same

subject is covered by identical patents in different countries, full reference is made and subject given under the first entry, and succeeding notices refer back to that one. Foreign patents have not been examined other than by the literature references. All U. S. patents have been examined in the specifications themselves.

An asterisk indicates mention by title only, or an abstract so brief as to be useless.

The author wishes to express his indebtedness to L. A. Pridgeon of the department of chemical engineering, University of Michigan, for much assistance in collecting the data on which this paper is based.

Growth of Canadian Paper Industry

After the depression of 1921 the present year has seen a remarkable expansion in the Canadian pulp and paper industry. For the year ended April 1, 1922, pulp and paper exports had a total value of over $180,-000,000, a figure exceeded only by exports of wheat and agricultural products. The Canadian newsprint mills now have a rated capacity of about 5,520 tons per day, equivalent to an output of 1,250,000 tons per year, which is double the output of any year prior to 1917. In addition, Canadian mills are equipped to produce 2,500 tons of pulp daily. The combined output represents a daily cut of 6,000 acres of forest land.

The Canadian pulp and paper industry is, in fact, accomplishing so much that it is a difficult matter to keep accurate trace of it, and statistics which apply today may be entirely incorrect tomorrow. According to government figures for 1920, the industry employed an invested capital of over $347,000,000, of which slightly more than half was in the Province of Quebec. In the first 6 months of 1922 Canadian mills produced over 516,000 tons of newsprint, as compared with 612,-000 produced by the United States mills. The Canadian newsprint output during this 6 months period is stated to have been 93.6 per cent of mill capacity.

While the volume of United States newsprint production has remained practically stationary at around 1,300,000 tons since 1913, Canadian production has increased from 350,000 tons to 812,000 tons in the same time. Exports to the United States have increased from 219,602 tons to 791,[illegible] tons. The United States has, in fact, come to depend on Canada for 85 per cent of the newsprint in addition to huge quantities of pulp. There is also an extensive trade being built up, and increasing rapidly, with the antipodes and the Orient, and in this regard the Pacific coast as a pulp and paper area is fast developing in importance. Total pulp and paper exports for the month of June this year amounted in value to $10,534,896, and for July $9,738,-252. Production in the latter month was nearly double that of the corresponding month in 1921, though, due to lower prices, the value was only slightly increased.

Bauxite in 1922

The domestic production of bauxite in 1922 was at least twice as large as in 1921 and may reach a total of not less than 300,000 long tons, according to the Geological Survey. This quantity is about half of that normally consumed.

During the first 6 months of 1922 the imports of bauxite averaged about 1,500 long tons a month, but since June they have been more than 3,000 tons a month. The prices of domestic dried bauxite ranged from $6 to $10 a ton, but were lower in the last half of the year. The prices of pulverized and dried bauxite have ranged from $12 to $15 a ton, and of calcined from $20 to $25 a ton. The effect of a shortage of coal is reflected in an increase in the price of calcined bauxite during the latter part of 1922. Under the new tariff the duty on bauxite is $1 a ton, whereas under the old tariff it was on the free list.

Materials for Furnaces and Ovens

Safe Temperature Ranges, and Data on Ability to Transmit Heat

DESIGNERS and constructors of ovens and furnaces, especially those operated by electric current, will find a great deal to interest them in a paper read by E. F. Collins, of the General Electric Co., before the Montreal meeting of the American Electrochemical Society, entitled "Electric Heat, Its Generation, Propagation and Application to Industrial Processes." The author calls attention to the fact that heat, light and electricity are only different manifestations of energy, and their phenomena follow identical laws. He then goes on to show how equations for the flow of electricity are analogous to those for the flow of heat. A number of tabulations of physical constants are given, so that a person familiar with the mathematical development can apply the theoretical expressions to given combinations of furnace materials.

We reproduce two of the simpler diagrams in Figs. 1 and 2. They chart in a very clear manner the capabilities and limitations of various materials of construction, and the duty demanded of different kinds of ovens or furnaces.

Another chart shows the limitations of the materials of construction when used in electrically heated equipment. These data are contained in Table I.

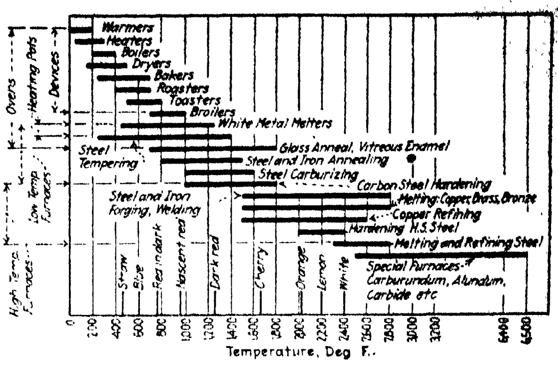

FIG. 1—TEMPERATURE RANGE IN INDUSTRIAL PROCESSES

TABLE I—LIMITATIONS OF MATERIALS

Material	Maximum Operating Temp., Deg. F.	Melting Temp., Deg. F.	
Resistors			
Tungsten	3,400		Oxidizes rapidly
Molybdenum	3,400		Oxidizes rapidly
Carbon	3,400		Oxidizes rapidly
Silundum	3,400		
Platinum	3,000		
Nickel-chromium alloy	2,200		
Aluminum steel	1,600		
Nickel	1,400		
Iron	600		
Refractories			
Firebrick	2,900	2,900	
Silica brick	3,100	3,100	
Chromite brick	3,400	3,950	
Magnesite brick	3,400	4,000	
Carborundum and alundum	3,400	4,060	
Heat insulators			
Magnesia	1,200		
Asbestos	800		
Kieselguhr	1,000		
Red brick	400		
Air cells	700		
Electrical insulators			
Porcelain	200		
Mica	800		
Fire clay	1,000		
Magnesium oxide	1,400		
Asbestos	1,000		
Alundum	2,400		
Containers and Carriers			
Cast iron	1,000		
Malleable iron	800		
Steel	600		
Nickel chromium alloy	2,200		
Monel metal	1,000		
Non-metallic refractories	2,800		
Calorized steel	1,600		

Hardening of Duralumin

"An Investigation of Duralumin" has been undertaken by S. Konno, under the direction of K. Honda, and the results of his findings are published in the *Science Reports* of the Tôhoku Imperial University, vol. 11, p. 269. He finds that the heating, quenching and aging phenomena are exactly similar to those when heating, severely quenching and tempering carbon steels. Hardening is due to the presence of the several elements and their possible compounds, present either by design or as impurities; but the aging effect is due principally to the dissolution of Mg_2Si in aluminum. Al_2Cu acts similarly, but to a very minor extent. Additions of Cu and Mn (duralumin) increase the hardness of Al:Mg alloys, but not the aging effect.

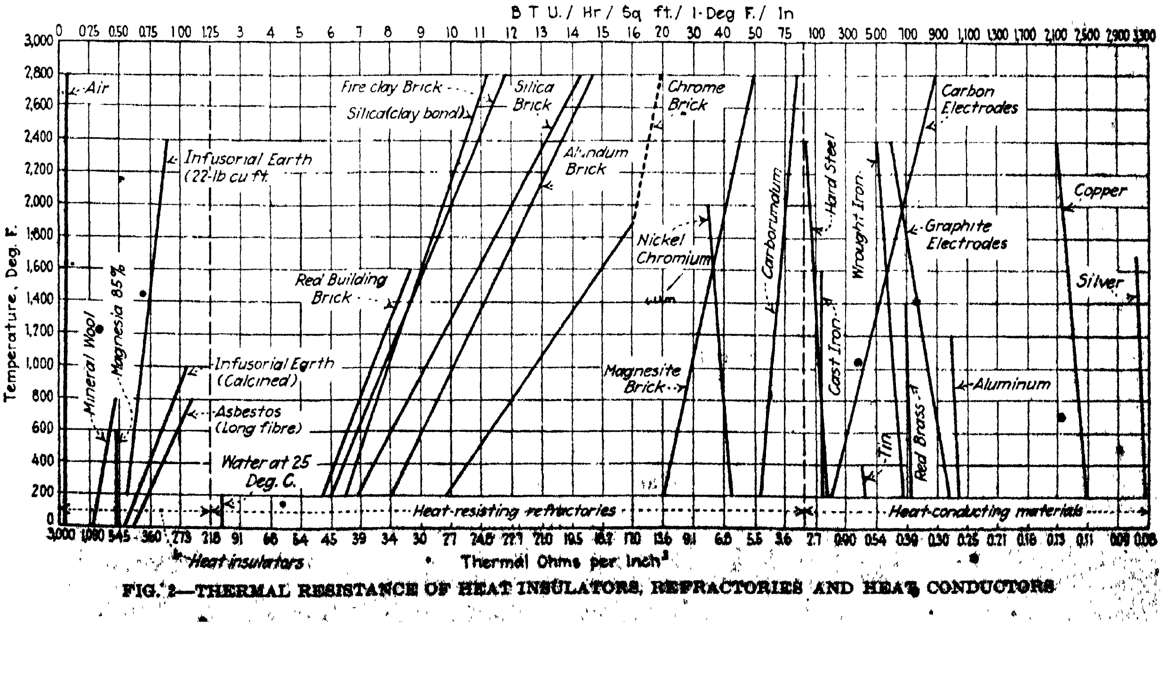

FIG. 2—THERMAL RESISTANCE OF HEAT INSULATORS, REFRACTORIES AND HEAT CONDUCTORS

Synopsis of Recent Chemical & Metallurgical Literature

Freezing or Galling of Threaded Pipe Joints

Couplings for heavy welded pipe of steel—such as oil well casings—have ordinarily been made of wrought iron. It is the usual experience that when coupling and pipe of the same metal are screwed together with considerable force, the joint will oftentimes seize or "gall" before many turns. This is really nothing but a low-temperature welding at excessive pressure. In a recent paper[1] before the American Petroleum Institute, F. N. Speller finds that steel couplings and pipe having die-cut threads can be driven three or four turns further than ordinarily if the coupling threads have previously been electroplated with zinc. Nearly as good results may be had by mixing a grease with 50 per cent by weight of zinc dust, and using this as lubricant.

Nickel and Chromium in Cast Iron

Richard Moldenke presented a paper on this subject before the San Francisco meeting of the Mining Engineers (September, 1922). It contains a summary of extended tests on standard bars made of various mixtures of cast irons containing up to 20 per cent of Bethlehem Steel Co.'s Mayari pig. He points out that this pig iron contains high carbon (4.25 per cent total) 1.2 per cent Ni, 2.4 Cr and 0.2 Ti, and is smelted with a large slag volume and heavy coke charges. All these are indications of a well-made iron, free of oxide, even approaching the general excellence of the older "charcoal irons"; and should produce castings of fine uniform grain.

When introduced into a cupola, about half the Cr is slagged; Ni persists, however. Chromium decreases the amount of graphic carbon in the resulting castings; nickel increases the strength. Large proportions of low-silicon Mayari pig will produce excellent white iron rolls, car wheels and crusher liners. Castings containing considerable Ni and Cr will also prove superior for heat- and acid-resisting purposes.

In all about 245 heats were poured, the compositions varying systematically, as follows:

Phosphorus	0.10; 0.40; 0.80
Total carbon	2.75; 3.25; 3.75
Silicon	0.75 to 2.75 by 0.25 steps
Mayari pig additions	0, 10, 15 and 20 per cent

Melting was done in a crucible furnace, and standard transverse test-bars poured. Breaking strength and deflection, Brinell hardness, tensile strength and chemical composition were determined for each heat. Results are tabulated in the paper, and a series of graphs drawn showing the effect of composition on these properties.

In general it was found that the Brinell hardness decreases as the total carbon increases, and is independent of the silicon content. Hardness and transverse strength also seem to be independent properties.

Silicon seems to weaken the transverse bars, as does also high total carbon and high phosphorus. On the other hand, nickel and chromium increase the strength, especially in low percentages. The strongest bars broke at about 4,900 lb. with a deflection of about 0.11 in. They contained total carbon about 3.25, Si 1.75 per cent, P less than 0.40 and Ni and Cr about 0.15 per cent each. This strength is about 600 lb. greater than similar analysis containing no Ni and Cr, although low-phosphorus irons containing no alloy showed superior ductility.

Book Reviews

OUTLINES OF THEORETICAL CHEMISTRY. By *Frederick H. Getman.* Third edition, thoroughly revised. xi + 625 pp., illustrated. John Wiley & Sons, New York. Price, $3.75.

The broad field of physical chemistry is completely covered—the properties of the different physical states of matter, equilibrium, thermochemistry, photochemistry, electrochemistry and radioactivity. The arrangement is logical and clear so that one sees that physical chemistry is an organized integral science and not, as in Walker's Physical Chemistry, a series of independent topics. Perhaps the author might well have made his classification still more rigid and obvious.

The subject matter in general has been brought thoroughly up to date (e.g., isotopes). However, no mention is made of the Bingham viscosimeter and other important types of viscosimeter; nor of the Menzies b.p. apparatus, nor of plasticity, nor of the science of microchemistry as developed by Chamot. One misses the periodic arrangement of elements according to their atomic numbers. In the description of the determination of atomic weights the author omitted to show the contribution of physical chemistry in the avoidance, decrease, compensation and correction of errors in precision measurements. On page 85 the author persists in speaking of molecular aggregates within a solid crystal and he ascribes to them a sort of Brownian movement. Like most texts upon physical chemistry, this book does not show explicitly how to use Van der Waal's equation and how to calculate the constants, and no problems upon this important and practical equation are given. The chapters upon electrical conductance and electromotive force have been, to a large extent, abstracted from LeBlanc's Electrochemistry, which is a book that has long needed revision. Electrometric titration and the concentration of hydrogen ions and pyrometry have been cursorily treated.

The book is convenient in form, the printing is clear and the paper is good. The diagrams and curves are abundant (148 figures), well selected and clear.

The text is adapted (and intended) for those who are beginning the study of physical chemistry. The student who has already received, according to modern practice, some instruction in physical chemistry in his courses in general chemistry, qualitative analysis and quantitative analysis will not be too advanced to use this book. It should serve very well as a text to teach from, as well as a book for self-study or for a review. Probably it is one of our best three texts of introductory physical chemistry.

RESTON STEVENSON.

STANDARD SPECIFICATIONS FOR LABORATORY APPARATUS ADOPTED BY THE MANUFACTURING CHEMISTS ASSOCIATION OF THE UNITED STATES

These pamphlets are on sale at the office of the Manufacturing Chemists' Association in the Woodward Building, Washington, D. C. The price is not given, but is probably moderate. A committee of the Manufacturing Chemists Association, of which E. C. Lathrop of the du Pont company was chairman, has worked out, together with the manufacturers of laboratory apparatus, the committee on laboratory apparatus of the American Chemical Society and the Official Association of the Apparatus Manufacturers, a set of specifications covering the more usual types of apparatus. It will scarcely pay to go into the details of these specifications. Suffice it to say that the work is in line with modern ideas of diminishing the cost of manufacture by standardizing equipment, and also gives a happy combination of the ideas of the consumer and producer. The Manufacturing Chemists Association seems to have borrowed a leaf from Mr. Hoover's notebook, and the laboratory apparatus becomes thus Hooverized. After a casual glance through the catalog, in which are shown detailed drawings of many of the pieces of apparatus, it is evident that a good deal of thought has been given to the choice of specifications, and the convenience of the operator has been the primary slogan of the committee.

CHARLES WADSWORTH.

Recent Chemical & Metallurgical Patents

American Patents Issued Dec. 26, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,439,683—Manufacture of Gasoline. R. F. Bacon and B. T. Brooks, Pittsburgh; assigned to Gulf Refining Co., Pittsburgh.

1,439,685—Production of Light-Colored Fatty Acids. J. W. Bodman, Western Springs, Iowa; assigned to William Garrigue & Co., Inc., New York City.

1,439,781—Crusher. M. F. Williams, St. Louis; assigned to Williams Patent Crusher & Pulverizer Co. of Missouri

1,439,865—Nickel Alloy. Leon Cammen, New York City; assigned to International Nickel Co. of New Jersey.

1,439,887—Vehicle for Paint Pigments. William G. Hall, California, Pa.

1,439,909—Production of Alkali Metal Cyanides. F. J. Metzger, New York City; assigned to Air Reduction Co., New York City.

1,439,921—Recovery of Gasoline From Natural Gas. E. A. Starke, Berkeley, Calif.

1,439,939—Low Percentage Manganese Steel. J. M. Blake, Chicago Heights, Chicago, Ill.; assigned to American Manganese Steel Co., Chicago, Ill.

1,439,960—Purification of Hydrofluoric Acid. Henry Howard, Cleveland; assigned to Grasselli Chemical Co., Cleveland, Ohio.

1,439,976—Conversion of Aromatic Ring Compounds Into Motor Spirit. A. S. Ramage, Detroit, Mich.; assigned to Chemical Research Syndicate, Ltd., Detroit.

1,440,006—Cellulose Acetate Composition. H. Dreyfus, London, England.

1,440,026—Evaporator for Acid Generating Liquids. H. A. E. Nilson, Sweden.

1,440,056—Making Urea Phosphate. F. Clarkson and J. M. Braham, Washington, D. C.

1,440,063—Guanidine Nitrate. T. L. Davis, Somerville, Mass.

1,440,018—Recovery of Phenol Vapors by Tar Oils. W. Runge, Orange, and H. A. Curtis, Maplewood; assigned to Bregeat Corp. of America, Wilmington, Del.

1,440,176—Vulcanizing Rubber. Eloi Ricard, Melle, France, assigned to Société Ricard, Allenet & Cie., Melle (Deux Sèvres), France.

1,440,194—Drying, Burning and Recovering of Finely Divided Material. Abraham Wijnberg, Amsterdam, Netherlands.

1,440,195—Same title as 1,440,194

1,440,211—Continuous Process for Manufacture of Caustic Soda and Caustic Potash. Camille DeGuide, Enghien, France.

1,440,256—Treatment of Hydrocarbons. G. F. Forwood, London, England; assigned to the United Kingdom Oil Co., Ltd., London.

1,440,352—Treatment of Oil Containing Water. O. C. Gatrell, El Dorado, Kan.

1,440,355 and 1,440,356—Suspension and Emulsion and Process for Making Same. J. C. Morrell, New York City.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Diolefine Polymerization Products—It has been known that by passing a mixture of acetylene and propylene through red hot tubes it is possible to obtain small quantities of 1.3 butadiene together with other hydrocarbons. Furthermore, the formation of diolefine is increased by use of contact agents and is probably influenced by the catalytic activity of other substances. Hermann Plauson, however, claims to have produced increased yields of these condensation products by gradually increasing the pressure and the temperature, or increasing the time of reaction. He submits a mixture of equal volumes of acetylene and ethylene to a pressure of from 3 to 15 atmospheres by forcing them into a long thick-walled spiral or zigzag steel tube. This is heated from the outside to 350-450 deg. C. By a special arrangement of the valves at the ends of the tube, the gases are permitted to escape as any desired pressure is obtained. The gases which escape are passed into a distillation apparatus and are first cooled with water and then in a freezing machine to 20 deg. C. The 1.3 butadiene and the higher boiling hydrocarbons are thus condensed from the unchanged gases, which are forced back into the tube by means of the compressor.

A second example cited by this patent involves the use of molecular proportions of allylene and ethylene, from which is obtained a diolefine hydrocarbon of the formula C_5H_8. When treated with metallic sodium, this compound is polymerized to yield a rubber-like product. A yield of 8 to 12 per cent is said to be obtained by a single passage of the gaseous mixture through the apparatus, and the total yield with continuous operation is about 75 to 78 per cent. Other examples cite the use of mixtures of acetylene and propylene and of ethylene, acetylene and benzene. The polymerized products obtained from each of these mixtures are said to be of use in oil varnishes and as turpentine substitutes. (1,436,819. Nov. 28, 1922.)

Varnish Compositions—An applica- of the Plauson colloid mill in the manufacture of varnish and similar paintable compositions is claimed in a recent patent granted to the mill's inventor, Hermann Plauson, of Hamburg, Germany. In general, the process consists of subjecting a mixture of a varnish base, a liquid dispersion medium and some sort of a dispersion accelerator to intensive mechanical disintegration, such as that obtained in the colloid mill which reaches a peripheral speed of about 2,000 meters per minute. According to one of the examples cited, 100 parts of benzene is mixed with 5 to 10 parts of acetone-soluble condensation products of the phenol-formaldehyde type, which have previously been treated with small quantities of acetone, in the presence of 1 to 5 per cent of a fossil resin. The mixture is disintegrated in the colloid mill. The suspension gradually begins at a peripheral speed of about 300 meters per minute, but is carried out satisfactorily only at a speed of about 1,500 to 2,500 meters per minute. This treatment is to be continued for 3 hours at a temperature not over 70 deg. C. The result is a homogeneous lacquer which is not a true solution of the base in benzene, but is a suspensoid colloidal dispersion. Varnishes similar to shellac can be obtained from other artificial resins, such as the oxidized pitches, cumarone resins, vinyl polymerization products, etc., or from natural resins, such as copal, asphalt colophony, etc.

The products described in this patent differ from ordinary varnishes in that the particles are so finely divided that they possess the power of remaining in permanent colloidal suspension. Although in practice they may be considered as ordinary solutions, they are in reality suspensoid colloids. (1,436,820. Nov. 28, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Oils, etc.—Mineral and other oils and fats are increased in consistency by the addition of a saponifying agent and a product obtained by partly splitting two or more fats or oils with sulpho-aromatic acids. These fats or oils are preferably split to an extent of not more than 50 per cent, the resulting mixture of substances being used without any separation. Only one of the oils may be split by means of sulpho-aromatic acids, the other one being split by any other reagent. One of the two oils is preferably castor oil. In an example, 5.75 kg. of castor oil is split to the extent of 43½ per cent by means of Twitchell reagent and 1.75 kg. of fish oil are added. The mixture is added to 100 kg. of a light mineral oil together with 8 kg. of 40 per cent soda lye. (Br. Pat. 185,782. Meyer zu Eissen and P. Kiederich, Berlin. Nov. 8, 1922.)

Motor Fuel—Naphthene acid, preferably purified, is added as a diluent to hydrocarbons in amounts of at least 5 per cent and up to 40 per cent by volume to form a motor fuel; or the acid is used in the form of its neutral or acid soaps to form fuels of the type described in specification 12325/14 in which water is incorporated as an emulsion. Cresol or carbolic acid or other phenols, preferably in proportions of 1 to 3 per cent by volume, or amyl or ethyl alcohol may also be added to the

water-containing fuels to render the mixtures stable. Examples specify the use of potash and ammonia soaps of naphthene acid, and of benzol with gas oil or kerosene oil. Preferably, the naphthene acid is added to the oil, the mixture treated with alkali, and the water added subsequently. (Br. Pat. 185,796. H. Kleinschmidt, Berlin. Nov. 8, 1922.)

Tin Electrolysis—An electrolyte for refining tin consists of an acid, preferably hydrofluosilicic acid, in which tin is dissolved and to which a relatively small proportion of phosphoric acid is added to render insoluble any lead contaminating the tin. The electrolyte is prepared by intermittently immersing baskets made of impure tin or hard rubber containing impure shot tin in oxidizing tanks containing a 15.5 per cent solution of hydrofluosilicic acid until the solution has taken up 4.5 per cent of its weight of tin; the baskets are then suspended above the tanks until it is necessary to regenerate the solution. The solution is continuously circulated between the oxidizing and the electrolytic tanks by a pump. Phosphoric acid is added before solution and from time to time during electrolysis; the proportion may be from 0.1 to 0.3 per cent; about 0.1 per cent of cresylic acid, and from 0.05 to 0.1 per cent of glue may also be added. Slabs of impure tin are used as anodes and sheets of pure tin as cathodes. Both sets of tanks are lined with asphaltum paint. (Br. Pat. 185,808. W. P. Thompson, Liverpool. Nov. 8, 1922.)

Treating Copper-Nickel Solutions—A process for the precipitation of copper by means of finely divided nickel from solutions containing copper and nickel is carried out at a temperature below that of exhaustion of the nickel. Bessemerized copper-nickel matte may be ground, roasted and leached with sulphuric acid; part of the leached residue is reduced to metal and is used in excess as a precipitant for the solution obtained from the remainder of the leached residue, the precipitation being carried out at normal temperatures, and preferably on the counter-current principle. The copper-nickel powder with the copper cemented thereon is roasted, preferably in admixture with roasted or unroasted matte. The process may be applied to the removal of copper from any nickel sulphate solutions and electrolytes—for example, in cyclic processes—so that heating and subsequent cooling are avoided. In the separation of nickel and copper by electrolysis, the nickel sulphate electrolyte containing sulphuric acid may be supplied to the cathode compartment and passed through a filtering diaphragm to the anode compartment, the impure nickel-copper solution formed being drawn off, purified as described above, and returned to the cathode compartment. (Br. Pat. 185,859. H. G. C. Fairweather, London. Nov. 8, 1922.)

Pyrazolone Dyes—Direct dyeing cotton dyestuffs of the tartrazine type are obtained (*a*) by condensing two molecular proportions of an aryl-benzthiazole hydrazine with one molecular proportion of dioxytartaric acid, (*b*) by coupling a diazo aryl-benzthiazole with a pyrazolone derived from an aryl-benzthiazole and acetoacetic or oxalacetic ester. An example of each method is given using (1) dehydrothiotoluidine monosulphonic acid and dioxytartaric acid, (2) diazotized dehydrothiotoluidine monosulphonic acid and the pyrazolone obtained by condensing the hydrazine from dehydrothiotoluidine monosulphonic acid with acetoacetic or oxalacetic ester; the products dye cotton orange shades fast to light and washing. (Br. Pat. 185,880. J. Baddiley, J. B. Payman and E. G. Bainbridge; assignors to British Dyestuffs, Ltd. Nov. 8, 1922.)

Leuco Vat Dyes—Reduction products of vat dyes (indigo, thioindigo, indanthrene, etc.) are converted into enolic ethereal salts which are stable in air, by the reaction of acids with the hydroxyl groups of the said reduction products. The conversion may be effected by general methods—for example, by action of an acid chloride on the leuco dyestuff in the presence of a tertiary base. The ethereal salts of sulphuric acid are obtained by the use of chlorsulphonic acid in the presence of a tertiary base, the product being then converted into a stable salt. In an example, dihydro-indigo is added to a pyridine solution of chlorsulphonic acid in an atmosphere of carbon dioxide and the mass diluted with water and crystallized; the pyridine salt so obtained is converted into an alkali or other salt.

Animal or vegetable fibers are dyed or printed with the above described compounds which are converted on the fiber into the dyestuffs by hydrolysis and oxidation, or by treatment with an oxidizing agent only; the latter method is available particularly in the case of sulphuric acid derivatives of dihydroindigo and dihydro-thioindigo, which are hydrolyzed and oxidized simultaneously by ferric chloride, bromine, chloride of lime, or the like, even in neutral solution. (Br. Pat. 186,057; not yet accepted. Durand et Huguenin, Soc. Anon., Basel. Nov. 8, 1922.)

Oil Emulsions—Oils, particularly mineral and tar oils, are subjected to high-speed disintegration in a colloid mill, such as that described in specification 155,836, in presence of water and of an insoluble mineral solid—for example colloidal graphite, calcined magnesia or magnesium carbonate. Talc or graphite may be added to increase the consistency of the product. Pastes are obtained when not more than 6 parts of water to 1 part of oil are employed; liquid emulsions when the water exceeds this proportion. The products are suitable for use as lubricants. Four typical compositions are as follows: (1) 1 part of viscous hydrocarbon oil, 1 part of colloidal graphite, 1 to 2 parts of water, and 1 to 3 per cent of coco-butter or like fat; (2) 1 part of low-temperature tar oil, 3 to 4 parts of water, and ½ to 2 per cent of magnesium carbonate, with or without 1 to 2 parts of graphite or talc; (3) 1 part of tar oil from Saxon brown coal, 3 to 5 parts of water, 1 to 2 parts of talc and 1 to 5 per cent of glycerine or glycol; (4) 1 part of fish oil, 5 to 8 parts of water and ½ to 1 per cent of calcined magnesia. Sulphonated castor oil may be used as a protective colloid. The provisional specification also states that the insoluble mineral solid may be dispensed with, and gives further examples. (Br. Pat. 185,779. Plauson's, Ltd., London. Nov. 8, 1922.)

Formaldehyde Condensation Products—Turbid materials, resembling meerschaum and porcelain, are produced by condensing urea with not more than 120 per cent of formaldehyde in the presence of at least 3 per cent of acid, the proportions being calculated on the pure anhydrous material in each case. The products are easily worked, and being porous, may be impregnated with coloring solutions, oils, resins, salt solutions, etc. Examples are given in which urea is dissolved in formaldehyde solution, the solution heated to effervescence, nitric, sulphuric or hydrochloric acid then added, and the whole finally emptied into molds. (Br. Pat. 187,605; not yet accepted. H. Goldschmidt and O. Neuss, Berlin. Dec. 13, 1922.)

German Patents

For complete specifications of any German patent apply to the German Patent Office, 97 Gitschinerstrasse, Berlin, Germany.

Recovery of Sulphur—Hot inert gases, such as the products of combustion of producer gas, are passed through a mass containing S—e.g., spent gas-purifying material—and the issuing stream of gas is cooled to a point above the melting point of sulphur, whereby liquid sulphur is deposited. A portion of the gas is subsequently withdrawn and the remainder is mixed with a fresh supply of hot gas and again passed through the material, or a portion of the gas may be circulated repeatedly through the mass before it is cooled. (Ger. Pat. 357,033. Badische Anilin u. Soda Fabrik.)

Solution for Use in Drawing Iron and Steel Wire—(*A*) A slightly acid solution of $CuSO_4$ is mixed with one or more chlorides—e.g., NaCl or $FeCl_3$. The iron or steel wire is coated with copper by immersion in this solution, and after drawing, the copper coating is removed by treatment with an ammoniacal solution of copper sulphate. By using the mixture of salts copper separates more easily than from copper sulphate alone, and the copper adheres better to the wire, so that a thinner coating can be used than hitherto.

(*B*) The medium consists of two or more suitable chlorides, including preferably $FeCl_3$, with the addition of sufficient ammonia to produce a certain quantity of colloidal $Fe_2(OH)_6$. By the addition of ammonia the solution adheres better to the wire and its lubricating action is increased. The composition of the solution remains unchanged and the wire keeps clean till the end. When the solution is to be used for pickling the ammonia is omitted. (Ger. Pats. 299,031 (*A*) and 299,032 (*B*). O. Vogel.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

American Association for Advancement of Science Holds Annual Meeting in Boston

The Chemistry Section Holds Symposiums on Photosynthesis, Ionization and Separation of Isotopes

ABOUT twenty-five hundred registered at the various conferences at the seventy-sixth meeting of the American Association for the Advancement of Science at Boston during the week Dec. 26 to 30. The meeting was noteworthy in several respects. In the first place, it showed an increasing disposition on the part of research men to pause in their labors and take account of stock. Many of the papers presented indicated a growing feeling that an investigator who gives the best that is in him to the search for truth can no longer content himself with the publication of his results and then rest secure in the conviction that the world will make a suitable use of his findings.

The recent outcroppings of medieval intolerance in various parts of the country, which have found their most prominent spokesman in William J. Bryan, are not to be lightly dismissed. They represent a well-financed and well-organized conspiracy to poison the spring of free scientific inquiry at its source and to dictate to students of science what shall be "truth" for educational purposes. The association as a whole therefore went on record in the most unequivocal way as to the scientific position of the biological theory of evolution in particular and the necessity of each man's drawing "the thing as he sees it, for the good of things as they are."

Proper Publicity Needed

It is recognized, however, that mere reaffirmation of fundamental truisms by a body of scientific men can have little effect as long as the message, spirit and content of science never reach a public which is constantly assailed by the clamor of fools and rogues. Science as it is must somehow "get across" to the great majority, and not remain buried in the dust of technicalities or appear travestied by the marvel mongers of the Sunday supplements.

There is needed a new and more

Sections Concerned With Engineering and Social Sciences Stress Place of Engineer in Civilization

ENGINEERING was represented at the meeting of the American Association for the Advancement of Science in two of the sections, Section K (Social and Economic Sciences), of which Dr. Henry S. Graves, of the Yale Forestry School, Yale University, is vice-president and chairman, and Section M (Engineering), F. M. Feiker, of the McGraw-Hill Co., Inc., New York, vice-president and chairman.

The keynote of the joint session between Section M and Section K was "The Relation of the Engineer to Conservation." John T. Black, State Health Commissioner, Hartford, Conn., presented a paper on conservation and industrial waste; William S. Murray, of New York City, spoke on the conservation of power.

Place of the Engineer

The keynote of the afternoon meeting of Section M was "The Place of the Engineer in Civilization," the principal paper being presented by Ira N. Hollis, president of the Worcester Polytechnic Institute. Dr. Hollis pointed out that from the dawn of history the emphasis has been placed upon the man who produces and the root names for producer in several of the earlier languages are synonymous with our definition of the term engineer. One phase or another of engineering activity enters into practically all the other arts and sciences. Dr. Hollis instanced the factor of transportation and communication as one vitally touching life and activities of men in all walks of life, and pointed out the engineer's place in the further development of transportation and communication systems in the world. Dr. J. B. Tyrrell, retiring vice-president of the section, in an address on "The Growth of the Mining Industry in Canada," pointed out the part that steam railway transportation played in the development of the mining industry as a practical illustration of the engineer's place in utilizing our natural resources.

Metric Association Marks Progress at Boston Meeting

Wider Adoption of Metric System Reported—Opposition Is Expressed From Army and Navy

Substantial progress toward the wider adoption of the metric system in America was emphasized Dec. 30 at the annual meeting of the American Metric Association, held in connection with the convention in the same city of the American Association for the Advancement of Science. Well-attended sessions at the Massachusetts Institute of Technology and a dinner at the Copley-Plaza Hotel featured the program. Dr. George S. Kunz of New York presided, and interest was increased at the meeting by the appearance of opponents, who spoke on behalf of the Secretary of War, the United States Navy and industrial organizations.

During its convention, the American Association for the Advancement of Science reaffirmed its belief in the metric system, and passed a resolution recommending the use of metric units by scientific men in all papers of a professional character, with non-metric units in parentheses. This expression of opinion was most gratifying to advocates of the metric system. The association voted to shorten its name to the Metric Association; approved the adoption of the liter as the measure of capacity between the British Commonwealth and the United States, and passed a resolution favoring the compulsory metric system bill now before the Senate.

Advantages of Adoption Stressed

Among the speakers who carried out the advantages of the universal adoption of the metric system were A. E. Kennelly, of Cambridge, Mass., who emphasized the value of common units in applied science in an address upon "The Metric System in Electrical Engineering." B. L. Newkirk, of the General Electric Co., in a paper on "The Metric System in the Electrical Industry," reviewed the growth of metric measurements in the past century and pointed out that there is no hope of getting the non-English speaking world to adopt non-metric units. "If the world is to get together at all, it must be on a metric basis," he said.

Captain Elliott Snow, of the Con-

Harding Approves the Three-Shift Day

President Pleased That Engineers Agree With Social Workers in Working Hour Program

The 12-hour day and the type of worker it produces have outlived their usefulness in American life, President Harding declares, commenting on the report of the committee on work-periods in continuous industry of the Federated American Engineering Societies.

This committee, after 2 years of investigation of more than forty continuous industries, including steel and iron, found that the 12-hour day was not an economic necessity. These findings, President Harding says, represent his "social viewpoint."

The President's statement, which will be embodied in the report now being compiled by the engineers, was given out in New York by the chairman of the committee, H. E. Howe of the National Research Council, Washington. It follows:

> It is a matter of very much gratification to me that the Federated American Engineering Societies, our foremost organization of American industrial skill, should have given 2 years of diligent inquiry, under competent experts, to a subject which is of very deep interest to me and important to the country.
>
> I rejoice to note the conclusions of this great body of experts are identical with those which I have reached from a purely social viewpoint. It has seemed to me a long time that the 12-hour day and the type of worker it produces have outlived their usefulness and their part in American life in the interests of good citizenship, of good business and of economic stability. The old order of the 12-hour day must give way to a better and wiser form of organization of the productive forces of the nation, so that proper family life and citizenship may be enjoyed suitably by all of our people.
>
> This clear and convincing report of the engineers must prove exceedingly helpful in showing that this much-to-be-desired result can be achieved without either economic or financial disturbance to the progress of American industry.

Members of the committee on work-periods, in addition to Chairman Howe, were J. Parke Channing, L. P. Alford, Fred J. Miller and Dwight T. Farnham of New York; Morris L. Cooke of Philadelphia, and L. W. Wallace of Washington. The field work was directed by Horace B. Drury of Washington, former member of the faculty of Ohio State University, and Bradley Stoughton of New York, chairman of the iron and steel committee of the American Institute of Mining and Metallurgical Engineers.

President Harding's declaration follows that of John D. Rockefeller, Jr., who in a recent statement favored the 8-hour day.

Standard Oil Co. Will Offer Technical Training to Employees

The Standard Oil Co. of California will soon inaugurate a correspondence course of instruction for employees in all parts of the state, designed to fit the students for better positions of technical character. The taking of the course is optional with the employees.

Nine Standard Formulas for Fertilizers Adopted by New England States

Reduction of the variety of mixed fertilizers which are to be offered for sale in the New England states to nine high analyses was agreed upon at a conference in Boston, Dec. 30, between agronomists representing the six states and representatives of manufacturers.

Analyses agreed upon as standard for New England are: 0-12-6, 2-12-4, 3-10-4, 3-10-6, 4-8-4, 4-8-6, 5-4-5, 5-8-7, 8-6-6.

The soil officials of the state colleges and experiment stations present agreed to recommend these analyses to the farmers of their states and the manufacturers agreed to push them, through their salesmen, above other analyses, although any of the present grades now being sold will be supplied upon request.

The New England meeting was the second at which state officials and fertilizer manufacturers have reached agreements to push high-analysis mixed fertilizers to the exclusion of a multiplicity of poorer grades, the first agreement having been reached at Chicago and affecting five of the Middle Western states. The present average tonnage of mixed fertilizer consumed annually in New England is about 130,000. Manufacturers representing 98 per cent of the tonnage sold in that section attended the Boston meeting, as did representatives of the soil improvement committee of the National Fertilizer Association.

A similar meeting is being arranged for the Middle Atlantic states, which are heavy consumers of fertilizer, to be held at an early date.

Large New Laboratory Dedicated at Stockholm College

New buildings and laboratories, constituting a department for chemical instruction which in size and equipment is second only to that of the largest American institutions, have just been opened by the Technical College in Stockholm, the ceremony of dedication being performed by the King of Sweden in the presence of a large assembly of prominent educators and men of affairs.

The chemical department at the Technical College now includes four laboraries, devoted respectively to research and instruction in organic chemistry, inorganic chemistry, technical chemistry, and electrochemical processes. There is also a laboratory for the study of fermentation. "The electrochemical industry is now of tremendous importance," said Prof. W. Palmaer, head of the department, in a speech at the opening exercises, "utilizing, as it does, the vast amount of power generated by the Swedish hydro-electric stations in the commercial production of a great variety of chemical and metallurgical products."

Memorials and congratulation were received from many educational institutions in neighboring countries.

Labor Shortage Discussed by A.I.M.E.

Desirability of Modification of Immigration Laws Discussed at New York Meeting

Establishment of a federal commission to study the nation's labor needs and recommend necessary changes in the present 3 per cent immigration law as a means of meeting the problem of a labor shortage was urged by Daniel Bloomfield, an industrial engineer of Boston, in an address before the Metropolitan section of the American Institute of Mining and Metallurgical Engineers at Rumford Hall, Jan. 3.

Mr. Bloomfield said that "taking down the bars of immigration without some definite, carefully devised program will not do."

"We must have a sound program," he said, "based on facts and dealing with the immigration on the basis of needs in order to help the situation." Mr. Bloomfield suggested that employees could help the situation by reducing the labor turnover, to make employment more regular in seasonal industries.

Federal Commission Suggested

"The next step in meeting the problem if labor shortage is likely to become acute," he continued, "might be a federal commission made up of a representative of the Department of Labor, Department of Commerce, representatives of employers, employees and the public groups to make a thorough study of the facts in the situaaion. If the facts then warrant action, Congress might modify the contract labor clause of the immigration law so as to permit this commission to bring in the type of laborers where work for them is guaranteed and for the period guaranteed by the concerns that need such labor. Such a commission, working with the immigration department, would act as a clearing house for labor and could so allocate labor that it would meet our needs. The per centum law might remain, but this commission could be given certain leeway in opening up or shutting down on the labor supply from abroad."

W. R. Ingalls, consulting engineer, said that he was not convinced that there was need of modifying the present immigration laws.

Countervailing Duties on Canadian Products Rescinded

The Treasury Department has revoked its orders directing imposition of customs duties on chloride of lime, calcium nitrate and cyanamide when imported from Canada. After the orders had been issued, close examination of the new tariff act disclosed that the retaliatory proviso of the calcium paragraph of the free list specifies only calcium acetate. The countervailing duty ordered on imports of this product from Canada stands and the others are rescinded.

New York Chemists Honor Pasteur

Joint Meeting of Metropolitan Sections Hears History of Great Scientist's Work and Modern Achievements That Grew from It

CHEMISTS of the metropolitan district gathered in Rumford Hall on Jan. 5, at a joint meeting of the New York Section of the American Chemical Society and of the Société de Chimie Industrielle, to commemorate the centenary of the birth of Louis Pasteur. Prof. Gary N. Calkins, of Columbia University, read a splendid paper on "Pasteur and the Science of Fermentation," and Prof. John N. Nelson, of Columbia University, spoke on "Pasteur and Chemical Asymmetry."

"No one science can claim Pasteur's genius," said Professor Calkins. Today the greatest expression of his genius is seen in his mastery of the method of science, particularly in medicine. Although he was not a physician or a biologist, by sheer ability to apply scientific methods he came to be recognized as a master in both sciences. Wherever he went, Pasteur was an initiator.

His Work on Fermentation

Pasteur's revolutionary work on fermentation was initiated by a Lille manufacturer of alcohol who came to Pasteur for advice on his process. At that time the ideas on fermentation were confused and hazy. The ordinary conception of the mechanism of fermentation as advanced by Liebig was entirely physical and did not recognize the essential part played in the process by living organisms. Pasteur first showed definitely that different activities of similar natures are brought about by living organisms and that different kinds of actions are caused by different species of bacteria. He saw the part played by micro-organisms in putrefaction. And he first conceived the life cycle and the part played by micro-organisms in putrefaction, the decay of living matter to ammonia, carbon dioxide, etc., in which form it is observed on plants by photosynthesis and again assimilated as food by living animals. The question naturally arose, Whence come these organisms? Up until the seventeenth century there was a very general belief in spontaneous generation. It was commonly accepted that lizards, flies, salamanders, etc., were generated spontaneously. Pasteur, with his characteristic, scientific thoroughness, experimented with sterile mediums instead of containers in contact with sterile air, and found that under such conditions no bacterial action was possible. His experiments demonstrated that the micro-organisms exist in the air, although for some time this theory was scoffed at and one of the proponents of the theory of spontaneous generation even went so far as to scout Pasteur's theory with the statement, "The air thus peopled would have the density of iron."

In 1865 Pasteur was called upon to study an epidemic which was causing havoc among the silk worms in the southern part of France, where the silk industry had already become a very flourishing business. In the six years that he was studying this problem he came to the conclusion that human diseases are caused by micro-organisms, in the same way that the disease was carried by the silk worm. This was really the beginning of Pasteur's far-reaching experiments on human diseases and the modern science of bacteriology.

Early Work on Chemical Asymmetry

Professor Nelson described Pasteur's early work on chemical asymmetry, which was done while he was a student at the Ecole Normale. At this time the first glimpse of chemical asymmetry had been obtained by Sir John Hershel, who pointed out that there are two varieties of quartz, one variety being, as it is called today, dextro-rotatory and the other laevo-rotatory. Certain organic substances were also known to be optically active. Pasteur conducted a number of experiments on tartaric acid and its salts. He came to the conclusion that the optical activity of tartrates was due to hemihedral crystals and that the difference between tartaric and racemic acids which had the same composition, properties, number of atoms and identical arrangement was simply in the different action on polarized light, which was due to the asymmetric arrangement of the crystal with the two substances. He also came to the conclusion that chemical asymmetry is caused solely by life forces. This conclusion has since been discredited, but nevertheless it was important because it was the origin of the present-day conception of fermentation. He also concluded that the asymmetry of two reactive bodies affects the properties of the resulting substance, a conclusion which is still tenable in the light of present knowledge.

This work extended from the year 1844 to 1860. It was important and far reaching enough in its consequences to constitute a commendable life work for the average man, but at its conclusion Pasteur stood only at the threshold of his career.

Selective Bacteriostatic Properties of Certain Dyes

The most interesting paper of the evening was delivered by Dr. John W. Churchman, of Cornell University Medical School, who spoke on "The Selective Bacteriostatic Properties of Certain Dyes." This was an especially timely subject in view of the fact that it represents a modern achievement in the field in which Pasteur was a pioneer. Chemical selection is one of the most interesting and one of the most mysterious phenomena of science. Some diseases affect only one race of human beings. Some diseases affect only one organ of the body. Lead palsy paralyzes all the numerous muscles in the wrist except one, which is apparently unaffected. Cocaine affects only the sensory nerves.

Ehrlich discovered that methylene blue injected in the blood stream picked out the nerve cells and maimed them, whereas it did not affect any other cells of the body.

A Scandanavian bacteriologist, Gramm, described the system of classification of bacteria which depends upon the staining action of gentian violet. The bacteria are stained with this dye, fixed with iodine, and then washed with alcohol. Some species of bacteria give up the color on this treatment and they are known as Gramm negative. Those which retain the stain are called Gramm positive. It has been found that the Gramm positive organisms are killed by stains, whereas the Gramm negative bacteria are not.

Dr. Churchman exhibited a number of flies which showed very conclusively that gentian violet exhibits highly selective properties in inhibiting the growth of certain species of bacteria. By the application of this principle it is possible to develop two strains of bacteria—those upon which gentian violet has a bacteriostatic action, and those which it does not affect. Sulphanilic acid, acid fuchsin, ethyl sulphonic acid also act selectively, but in exactly the opposite way.

Chemical Salesmen's Association Begins Lecture Course

Forty-six members of the Salesmen's Association of the American Chemical Industry turned out for the first lecture in Dr. F. E. Breithut's course in chemistry for salesmen at the City College of New York, Jan. 4. Dr. Breithut spoke on the subject of "How the Chemist Works" and it was a most interesting and comprehensive lecture. He explained, in non-technical terms, the functions of common laboratory equipment and gave a good idea of the chemist's technique.

Fifty-three members of the association have enrolled for the course, and others are expected to sign up before the next lecture. The members of the course include representatives of the following firms: American Cyanamid, Noil Chemical Co., Industrial Chemical Co., Marietta Refining Co., Peerless Color Co., Mathieson Alkali, Dow Chemical Co., Warner Chemical Co., B. J. Seydel Manufacturing Co., Edward Hill's Son Co., Roessler & Hasslacher, Marx & Rawolle, E. Fougera & Co., and the Mallinkrodt Chemical Co. Lectures will be given every Friday evening at C.C.N.Y. for 12 weeks.

Cash prizes have been offered by Williams Haynes for the three best essays by members of the course, on "The Value of Chemical Knowledge to Salesmen." The essays will be judged by a committee composed of F. E. Breithut, J. W. Boyer and D. H. Killeffer.

American Association for Advancement of Science

Chemistry Section Symposium

Continued from page 83

effective mechanism of publicity; a means by which the scientific temper of the progressive thought of the world today may somehow be made a part of the working mental equipment of the "average newspaper reader." A great beginning in this respect has been made by the establishment of "Science Service," a sort of Associated News for science, with offices at Washington, D. C., under the experienced guidance of Dr. E. E. Slosson, sometime editor of the *Independent* and author, among other things, of "Creative Chemistry."

Symposium on Photosynthesis

Not content with his publicity work alone, Dr. Slosson gave one of the most interesting of the general papers presented, speaking at the symposium on photosynthesis. This was an attempt at an exhaustive inventory of possible sources of mechanical power. Besides the usual indirect utilization of solar energy by means of winds, tides, waves, water power and the storage of rainfall, the exploitation of fuels, etc., Dr. Slosson spoke of the possibilities of tapping the internal heat of the earth, the internal energy of atoms, dodging the second law of thermodynamics by sorting out fast molecules from slow ones, the use of photoelectric cells, and the exploitation of differences of temperature whether spatial (on the surface of the earth) or temporal, as between summer and winter. These and many other possibilities were passed in rapid review and formed an interesting introduction to the other papers on photosynthesis.

Dr. Spoehr, of the Carnegie Institution, was erudite and exhaustive. He left the listener crushed with the complexity of the photosynthetic problem and reported the failure of a long series of attempts to duplicate E. C. C. Baly's reported synthesis of formaldehyde from CO_2 and H_2O in ultraviolet light. Dr. Bovie, of the Haward Medical School, gave an entertaining but somewhat sketchy account of his own speculations in the field, enlivened by slides of hypothetical atomic structures and intersecting force fields, ending with a diagram showing the "hungry" amino-acid molecules inside a chloroplastid, attaching their polar groups to wandering molecules of H_2CO_3 in the plastid membrane. The carbonic complexes then rolled themselves up into rings and formed sugars.

S. E. Shepperd, of the Eastman Kodak Co., ended the discussion in a somewhat more hopeful vein. He first pointed out that interest in photochemistry is on the increase, due to the recent technical development of powerful sources of ultra-violet light, such as mercury vapor arcs in fused quartz, white flame carbon arcs and condensed spark discharges. These have enabled the efficiencies of many commercially promising processes to be studied in a comparative way and the validity of Einstein's law of photochemical equivalence has been confirmed in general, when the case is not complicated by side reactions. The outstanding commercial problem is to find new photochemical catalysts which, like chlorophyl, will take the relatively long wave length radiation in sunlight and hand it over to the chemical system in the form of the shorter wave length the system needs in order to become reactive.

Electrolytic Dissociation

Besides this session, many others contained papers of chemical interest. The discussion was most active in the session on ionization, in which D. A. McInness of M.I.T. ably presented the case for the complete dissociation of strong electrolytes which is based on the undoubted chance in the mobilities of the ions with concentration as shown by transference experiments. C. A. Kraus of Clark University and E. W. Washburn defended the opposite viewpoint and it seemed clear that the case is not fully settled, although the naïve view that the degree of dissociation of an electrolyte is always given by the ratio of the conductivity to the conductivity at infinite dilution must certainly be relinquished.

F. G. Cottrell showed slides of the Fixed Nitrogen Research Laboratory and outlined its work. Dr. Washburn described the new International Critical Tables of Physical Constants which are in preparation. These will be more complete than anything of the kind previously done and will include commercial materials as well as pure substances.

Separation of Isotopes

Much interest was aroused by W. D. Harkins, of the University of Chicago, who gave a résumé of his publications of the last 6 years dealing with the isotopic complexity of the elements, the structure of atomic nuclei, etc. He also described the recent progress of his students in separating the elements into their isotopes on a large scale, showing some fair-sized samples of mercury which differed by as much as a tenth of a unit of an atomic weight.

S. A. Mulliken, also of Chicago, described his own success in separating mercury to about the same extent by evaporation and diffusion through filter paper.

T. W. Richards, of Harvard, brought forward a new and very plausible method of calculating the diameters of the ions in crystals based upon compressibility data and his theory of compressible atoms. Professor Kraus emphasized the importance of his view that typical metals and typical electrolytes are really fundamentally similar, the negative electrons of the metal taking the place of the negative ion of the salt.

Jacques Loeb, of the Rockefeller Institute, presented his interesting view that proteins are not colloids in the sense of being molecular aggregates, but merely large single amphoteric molecules that are essentially like ordinary acids and bases. Enthusiasm for this idea was widely expressed, but on the other hand, many opposing views were mentioned, so that discussion on the subject promises to continue for some time.

The chemists concluded the session with a smoker at the American House. Santa Claus distributed presents, the *Pathetic Weakly* showed movies of chemical events and Dr. Slosson gave one of his brilliant talks. J. F. Norris of M.I.T. was the presiding officer.

Election of Officers

Dr. Charles D. Walcott, secretary of the Smithsonian Institution of Washington, was elected president for the year 1923 at a meeting of the council. Dr. Walcott has been secretary of the Smithsonian Institution since 1907. From 1894 to 1907 he was director of the United States Geological Survey, and from 1902 to 1907 he was the first director of the Reclamation Service. He is president of the National Academy of Sciences, a member of the National Research Council and chairman of the National Advisory Committee for Aeronautics.

Vice-Presidents Selected

Ten vice-presidents were elected, each representing a section of the association:

For the Chemical Section, Prof. E. W. Washburn of the University of Illinois and vice-chairman of the National Research Council.

For the Botanical Section, Prof. C. J. Chamberlain of the University of Chicago.

For the Anthropological Section, Assistant Prof. E. A. Hooton of Harvard.

For the Section on Social and Economic Sciences, John F. Crowell, director of the World Market Institute of New York.

For the Mathematical Section, Prof. Harris Hancock of the University of Cincinnati.

For the Physical Section, Prof. W. F. G. Swann of the University of Minnesota.

For the Geological and Geographical Section, Dr. Nevin M. Fenneman of the United States Geological Survey.

For the Zoölogical Section, Prof. Edward L. Rice of Ohio Wesleyan University.

For the Psychological Section, Prof. Raymond Dodge of Wesleyan University, Middletown, Conn.

For the Agricultural Section, President Raymond A. Pearson of Iowa State College of Agricultural and Mechanical Arts.

Section Secretaries Chosen

Two secretaries of sections were elected; Prof. W. D. Harkins of the University of Chicago being chosen for the Chemical Section and Prof. R. J. Terry of Washington University, St. Louis, for the Anthropological Section.

American Association for Advancement of Science

Engineering and Social Science Sections

Continued from page 83

Dr. Hollis, as well as Harrington Emerson, another speaker of the afternoon, pointed out the need of the engineer's analytical study of facts for the solution of present-day problems, and both emphasized the idea that indirectly the engineer, because of his control of the instruments of production, is deeply concerned with present-day civilization. The paper by Prof. C. F. Scott, of Yale University, president of the Society for the Promotion of Engineering Education, on "New Phases of Engineering Education," was presented in Dr. Scott's absence by Dr. Dugald C. Jackson. Professor Scott in his paper indicated that because engineering was coming to take such a large place in our modern life it was essential that the training of engineers be approached with a new viewpoint of the engineer's place in the community.

The several contributions emphasized that the next step in engineering is to relate the problems of the material advance in civilization to the human problems of civilization, and that the engineer has an opportunity for leadership in approaching these human problems which have grown out of his own contributions in increasing the perplexity of life if he will apply the logic of his thinking with the understanding that human problems are problems of emotion as well as of logic.

PAN-AMERICAN RELATIONS

In the evening Calvin W. Rice, secretary of the American Society of Mechanical Engineers, presented an illustrated address on the engineering and scientific developments of South America. Mr. Rice pointed out three definite opportunities for the immediate association of engineers between North and South America: First, the development of a common understanding of standards, the start of which was made very definitely at the international engineering congress held at Rio de Janiero; second, the development of an English-Spanish dictionary and glossary of engineering terminology, and third, the development of an interchange of thought between engineering societies of North and South America. In this connection, Mr. Rice stated, Verne L. Havens, editor of *Ingeniería Internacional*, had been made permanent secretary of the International Engineering Congress. He also recounted the personal contacts that had been established in the various government and engineering societies to bring about this more intimate engineering understanding between the two continents. Mr. Rice's lecture was illustrated with lantern slides showing engineering developments in South America.

Largest Memorial Fund to Honor Ramsay

The largest sum ever raised to honor a man of science has been contributed to the memorial for Sir William Ramsay. The amount of the fund is more than $500,000.

Former Premier Asquith of England was president of a committee which, in 1917, made an appeal for £100,000 to be devoted to a Ramsay memorial. Later the Prince of Wales became patron of the fund. The sum collected in cash is £57,645. It has been augmented by research fellowships instituted by various dominion and foreign governments, to the value of about £60,000.

The cash sum includes subscriptions from Great Britain and Ireland, America, Australia, Canada, Chile, China, Denmark, Spain, Holland, India, Italy, Japan, New Zealand, Norway, Straits Sett'ements, France, Greece, Switzerland and Portugal.

The money, according to a report in *Science*, will be devoted to the erection of a chemical laboratory at University College, London, and to founding the Ramsay memorial fellowships in chemical science for British students. Each fellowship is of the value £300.

Feldspar Colloquium Planned by American Ceramic Society

At the meeting of the American Ceramic Society in St. Louis, there was started a discussion on feldspars which aroused much interest; this discussion was focussed chiefly on milling problems, with only incidental reference to questions of quality and methods of determining quality. Judging from prevailing sentiment, the time is ripe to move on toward the formulation of specifications, and at the request of the officers of the whitewares division, the organization of a colloquium on the subject is being undertaken.

The purpose of specifications such as it is hoped to evolve is not to enable the consumer to get more for less money, but to establish and define various grades of feldspar. It is a problem of classification rather than specification. Classification may be made on the basis of the intended use, the chemical composition, mineralogical origin, physical properties, or any combination of these. The classification according to use is derived from the properties of the material, and the latter are the important values to define. Some of these properties are fixed by nature; thus the fusion point depends on the chemical composition and apparently also on the mineralogical origin of the rock. It is believed that the members of the society are in possession of the data needed, and they are urgently requested to contribute to the program to be presented at the forthcoming meeting.

All communications on this subject should be addressed to Edward Schramm, of the Onondaga Pottery Co., Syracuse, N. Y.

Metric Association Marks Progress

Continued from page 83

struction Corps of the United States Navy, opposed the general adoption of the metric system in industry, emphasizing the difficulties which shipbuilding would face in such an event. Major L. A. Nicholson, of the U. S. Army, presented a letter from Secretary of War Weeks, which opposed the passage of a compulsory metric bill by Congress, chiefly on the ground that it would cost about $3,500,000 to change existing war material in linear dimensions, and the same amount to change angular dimensions to a metric basis. Secretary Weeks declared that the forced adoption of the metric system would adversely affect both the supply of material and the industrial draft for war purposes.

E. A. Marsh, consulting superintendent of the Waltham Watch Co., and T. H. Miller, of the DeLaval Separator Co., reviewed the successful use of the metric system in their plants. Edward Richards, of New York, discussed the advantages of the metric system in forestry and lumber measurements, claiming that with the metric system more accurate sizing of lumber to meet future computations of strength of material in houses and other building would result.

F. H. Chase, of Boston, gave a talk upon the literature of weights and measures at the Boston Public Library during the afternoon, and this was followed by an inspection trip. The dinner at the Copley-Plaza was informal, and among the speakers were Dr. A. E. Kennelly, Dr. Hoffman, of the Babson Organization; Prof. R. A. Fessenden, of Boston; Captain Snow; Robert Spurr Weston, of Boston; Walter Wood, of Philadelphia; F. L. Roberts and B. L. Newkirk.

ELECTION OF OFFICERS

Dr. Kunz was re-elected president of the association, the vice-presidents being A. E. Kennelly, T. H. Miller and W. J. Schiefflin. Howard Richards was re-elected secretary, and F. L. Roberts treasurer, with headquarters at 156 Fifth Ave., New York City. The publication of a monthly bulletin and the formation of a Metric League were proposed at the dinner, and will probably be carried forward soon.

Canadian Paper Mills Increase Operations

The announcement is made of a new pulp and paper mill to be erected at Kaslo, B. C., Canada, by Howland & Waltz of Minneapolis, who at present operate a sawmill at Kaslo and have big timber limits there. In addition to the large body of standing timber which they control, there is plenty of water power available for hydro-electric purposes.

Preparations are also being made to reopen the Whalen Pulp & Paper Co.'s pulp mill at Swanson Bay.

Difficult to Find Successor to Stratton at Bureau of Standards

No progress has been made in the search for a director for the Bureau of Standards to succeed S. W. Stratton, who retired from the government service to accept the presidency of the Massachusetts Institute of Technology. Due to the fact that industry is making much more extensive use of research laboratories, physicists, according to Commerce Secretary Hoover, are very scarce. As a result the level of salaries has risen greatly. Where physicists formerly commanded salaries ranging from $3,500 to $5,000, many of them now are being paid from $10,000 to $20,000, Secretary Hoover says. This, he declares, makes it very difficult for the government to find an ideal man for this place when it requires a physicist in the front rank of his profession, willing to work for $6,000.

Exhaustive Study of Carboy Problems Concluded by Trade Association

A final report has been submitted by the carboy test committee to the executive committee of the Manufacturing Chemists' Association. The recommendations, which will not be made public until after the report has been considered by the executive committee, probably will be embodied in the regulations governing the shipment of carboys.

Under the direction of Guy E. Carleton, the committee has made by far the most exhaustive tests of carboys ever attempted. They cover the physical properties of the container, the closures, the package surrounding the carboy and the recovery of broken and chipped carboys. Drop, swing and concussion tests were pursued exhaustively. Shocks were carefully calculated. Observers traveled in box cars loaded with carboys to note their behavior under the conditions of actual transportation.

Physical Chemistry Symposium Planned Under Svedberg

The Rochester section of the American Chemical Society has been very fortunate in securing Prof. Thé Svedberg, University of Upsala, Sweden, to act as presiding officer of a symposium on physical chemistry which will be held in Rochester on Friday and Saturday, Jan. 19 and 20.

Papers will be presented at this symposium by prominent physical chemists from Schenectady, Cornell, Syracuse, Buffalo and Rochester. Practically every phase of physical chemistry will be considered, with the exception of colloids. On this phase there will be no papers, since a colloid symposium will be held at the University of Wisconsin later in the year.

The Rochester section extends a personal invitation to anyone interested in this physical chemistry symposium to be present and take part either in the presentation of papers or in the discussion which will follow the papers.

Department of Commerce Hopes to Collect Dye Import Figures

Itemization of dye imports is under active consideration at the Department of Commerce. If money can be found with which to undertake this work, these figures will be made available to all interested through the usual publicity channels of the department.

Chilean Nitrate for Sale

Bids for 28,000 short tons of sodium nitrate will be received by the Ordnance Salvage Board, Army Building, 35 Whitehall St., New York, until noon, Jan. 30. The material is in storage at the Old Hickory Powder plant at Jacksonville, Tenn. Purchases of 100 tons or more may be made.

Personal

Dr. M. S. BENJAMIN, professor of agricultural chemistry in the Hawkesbury Argricultural College, Richmond, New South Wales, Australia, recently paid a visit to the chemical laboratories maintained by the government in Washington.

Captain J. L. BROWN, who during the war was ordnance inspector of the powder plant of the Hercules Co. at Dover, N. J., is now representative of the New Jersey State Department of Sanitary Engineering, with headquarters at Newark.

Dr. CALVIN ADAM BUEHLER of the Ohio State University has been appointed assistant professor of chemistry in the University of Tennessee, Knoxville, Tenn.

CURTIS R. BURNETT, an official of the American Oil & Supply Co., Newark, N. J., has been re-elected president of the Ironbound Manufacturers' Association, composed of industrial interests in the Ironbound section of the city.

Dr. GUSTAV EGLOFF, director of research at the Universal Oil Products Co. of Chicago, is spending a week in New York and Philadelphia in connection with that company's business.

W. R. INGALLS of New York, DANIEL BLOOMFIELD of Bloomfield & Bloomfield, Boston, and B. F. TILLSON of the New Jersey Zinc Co. were the principal speakers at a discussion of the general subject of immigration at a meeting of the New York Section of the A.I.M.E. held at the Chemists' Club, Jan. 3, 1923.

ARTHUR LAZARUS has resigned as chief of the cost accounting bureau of the Chamber of Commerce of the United States, to resume professional practice, with offices in Washington and New York.

Dr. JUAN DE LA CRUZ POSADO, an engineer of Colombia, is spending several weeks in New York City and vicinity in the interest of a number of South American industrial enterprises. He expects to return to Colombia late in January.

OLIVER C. RALSTON, superintendent of the Pacific Experiment Station of the U. S. Bureau of Mines, at Berkeley, Calif., recently addressed the California Section of the American Chemical Society. His subject was "Aluminum Chloride, Its Manufacture and Uses."

E. E. THUM, associate editor of *Chem. & Met.*, recently addressed chapters of the American Society for Steel Treating at Worcester, Springfield, Hartford and Philadelphia, speaking on the subject, "Educating the Metallurgist and the Management." During February he will speak before other chapters at Pittsburgh, Cincinnati and South Bend on a similar topic.

Prof. WALTER G. WHITMAN, formerly assistant professor of chemical engineering, has been appointed assistant director of the Research Laboratory of Applied Chemistry of the Massachusetts Institute of Technology.

Obituary

WILLIAM R. WALKER died on Dec. 20. According to the *Iron Age* he was born at LaPorte, Ind., Nov. 26, 1857, and his career was closely identified with the iron and steel industry. His first employment was with the North Chicago Rolling Mill Co., Chicago; then he was appointed chemist for the Crown Point Iron Co., Crown Point, N. Y., and later he was with Spang, Chalfant & Co., Pittsburgh, as works superintendent. He was early associated with Robert Forsyth, the well-known steel works engineer, who constructed the South Chicago works of the North Chicago Rolling Mill Co. in the '80s. Prior to 1890 Mr. Walker was works manager of the Union works of the Illinois Steel Co., Chicago, and later became general manager of the South Chicago works for the same company.

At the time of the formation of the United States Steel Corporation in 1901 Mr. Walker was appointed assistant to the president, a position which he held at the time of his death. He gave special attention to metallurgical research and to improvements in operation and production. In the words of President James A. Farrell, "Mr. Walker was a man of keen mental attainments and possessed an exceptional knowledge of the iron and steel industry from both scientific and practical standpoints." Mr. Walker was a member of many technical associations and took a leading part in their activities. He was highly esteemed by his associates in the United States Steel Corporation and in the iron and steel industry.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Recent Trend of Prices

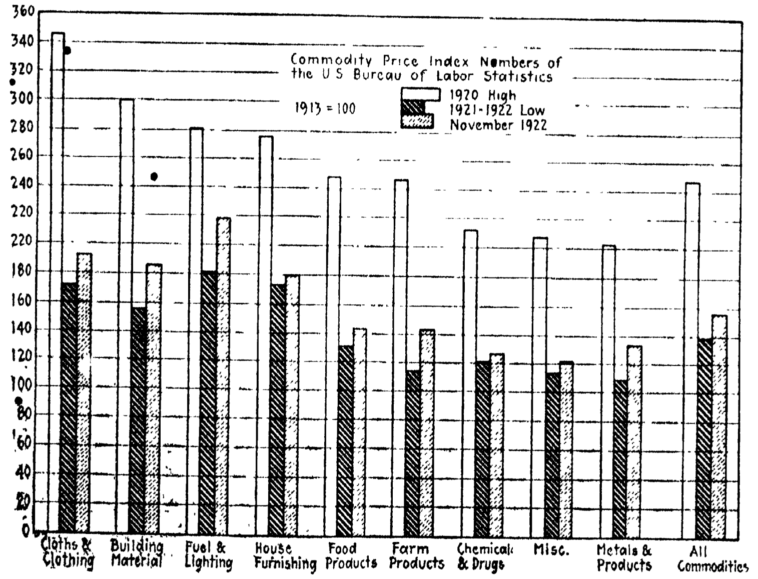
Uneven Recovery During 1922 Has Not Completely Corrected Past Disparities

A year ago it was complained that there was a maladjustment of prices, that disparities among the great groups of commodities seriously curtailed buying power, particularly of the farmer and the producer of certain raw materials. Today these conditions have been corrected to a certain extent, but there is still considerable evidence of distortion. The pronounced recovery of farm products has been beneficial, but the strikes in the mines and on the railroads have caused an altogether disproportionate rise in fuel prices. Furthermore, the record building boom of the past year has been accompanied by a marked stiffening of the prices for building materials.

TABLE I. CHANGES IN WHOLESALE PRICES IN 1922

Group	January, 1922	November, 1922	Net Gain
Building materials	157	185	28
Fuel and lighting	195	218	23
Metal and metal products	112	133	21
Farm products	122	143	21
Cloths and clothing	176	192	16
Food products	131	143	12
Miscellaneous	117	122	5
Chemicals and drugs	124	127	3
Housefurnishings	178	179	1
All commodities	138	156	18

Table I and the accompanying figure show the net changes that occurred during the first 11 months of 1922. In both, prices in 1913 are taken as a basis of 100.



A COMPARISON OF WHOLESALE PRICES SINCE 1920

The Government Indexes

The "all commodities" index of the United States Bureau of Labor Statistics rose from 138 in January, 1922, to 156 in November, 1922, a gain of 18 points. During this period the index for building materials showed a net change of 28 points, fuel and lighting 23 points, and farm products 21 points. On the other hand, the groups headed Miscellaneous, Chemical and Drugs; and Housefurnishings showed much lower gains—namely, 5, 3 and 1, respectively.

Record Buying by the Railroads

Railroad purchasing is often regarded as an important index of general buying, and certainly it bears a very vital relationship to activity in the steel industry. It is significant, therefore, that in 1921 only 239 locomotives and 23,346 freight cars were bought by the railroads, while in the first 11 months of 1922 ten times as many locomotives and six times as many cars were purchased. The figures for 1922 are 2,175 locomotives and 139,257 freight cars, according to a recent compilation made in connection with a general survey by the Harvard Economic Service.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	173.79
Last week	171.30
January, 1922	144
January, 1921	181
January, 1920	242
April, 1918 (high)	286
April, 1921 (low)	140

The continued strength of the cottonseed oil market was sufficient to offset slightly lower prices on ammonium sulphate and linseed oil. This index has shown a gain of almost 30 points during the past year.

Healthy Business Prospects in Heavy Chemicals

1923 Contracts Will Tax Capacity of Productive Equipment in Many Branches of the Industry

In general there are but few better indexes of business condition than is the heavy chemical industry. Products such as caustic soda, sulphuric acid and soda ash enter into practically every line of industrial activity. When it is stated, therefore, that 1923 holds prospects for "good, steady, healthy business" in heavy chemicals, it is safe to draw the inference that the nation's entire industrial life is in for a healthy improvement.

The president of the Mathieson Alkali Works, Inc., in an article appearing in the special chemical section of the *Journal of Commerce* (New York), is authority for the following statement:

> The heavy chemical industry has continued its work of eliminating speculative middlemen who became so prominent during the war period, with the result that violent fluctuations in heavy chemical prices have become almost a thing of the past.
>
> In the face of the increasing costs that began last fall, due to fuel, labor and freight rates, the larger companies of this industry apparently were willing to contribute their part toward the deflation of the industrial and commercial life of the country; consequently, when 1923 contracts were taken up, the larger manufacturers seemed to have attempted to maintain the prices of 1922 with few exceptions, where advances were absolutely necessary. It remains to be seen whether or not the purpose aimed at will work out in practice.
>
> The year 1923 should hold out a very encouraging outlook for a good steady, healthy business, provided business is not interfered with by attempted class legislation at Washington and attempts of certain classes to maintain their war wages, while wanting everything else reduced. Furthermore, it is our belief that the limit of the country's heavy chemical activities will not be that of plant capacities, but will be that measured by the supply of labor, which incidentally will probably be the experience of the entire industrial life of the country.

Chemical Prices at Higher Levels as Business Expands

Arsenic and Its Derivatives, Bleaching Powder and Copper Sulphate Feature Chemical Market—Acetate of Soda Makers Reduce Prices

MOST chemical prices in the New York market during the past week were well maintained and manufacturers were inclined to believe that expanding industrial activity during the year would serve to keep figures at fairly high levels. Arsenic still continued to head the list and material on spot remained in exceedingly light supply. Lead arsenate and calcium arsenate remained quite steady in sympathy with the arsenic situation. Trading in formaldehyde slackened considerably during the interval, but producers intimated the possibility of a new price advance, due to the steady rise in producing costs. Manufacturers of acetate of soda announced a reduction of ¾c. per lb. on material at the works, presumably in order to stimulate consuming interest. Producers of bleach reported a completely sold up market, with the demand far exceeding the supply.

Copper sulphate prices have remained very firm in producing quarters, in view of the fact that the metal has advanced considerably during the past few weeks, and there has been a steady demand by agricultural interests for contracts over the coming season. The alkali market for export remained quiet, although the domestic demand continued very strong. Prussiate of soda and barium chloride were somewhat easier in a very quiet market. Producers of salammoniac reported a steady contract call from the domestic trade. Oxalic acid remained practically unchanged at recent levels.

Principal Price Changes

Acetate of Soda—Leading producers announced a reduction, due to the weakened demand from the consumer. The general range is around 6¾@7c. per lb, f.o.b works.

Alcohol — Producers continued to quote former levels, but intimated an early increase on methanol. The 95 per cent grade is quoted at $1.23 per gal. and 97 per cent at $1.25.

Arsenic—Manufacturers are completely sold up at the works and are not eager to accept future orders. Export shipments have been coming in at a very slow rate from Japan and Germany and it is very doubtful if any recovery will be accomplished within the first quarter. Spot stocks were quoted at 16c. per lb., with future held at 15½c.

Barium Chloride—Importers reduced spot goods to $90@$95 per ton, depending upon quantity. Domestic producers reported a fair call from consumers and quoted carload lots at $95 per ton, f.o.b. works.

Bleaching Powder—This product is fast becoming one of the leading features of the market. It is quite certain that prices will be materially higher before the spring season, since manufacturers are completely sold up. In some instances deliveries cannot be made until the latter part of February. Contracts for carload lots, f.o.b. works, were heard around $2 per 100 lb., with odd spot at $2.30@$2.50 per 100 lb.

Formaldehyde — The demand has eased up somewhat, but prices were well sustained. Leading producers intimated another increase for the near future. Spot material was quoted at 16c. per lb., carload basis.

Lead Arsenate—Producers were very firm due to the scarcity of arsenic. Prices for limited stocks were heard around 21c. per lb.

Sal Ammoniac—Manufacturers were quite satisfied with the volume of contract business. Quotations among first hands ranged around 7½c. per lb. for the white granular and 7¾c. for the gray. Resale goods of imported quality were held at 6½c. per lb. for white and 8c. per lb. for gray.

Caustic Soda — Consuming interest continued along fairly active lines and prices ex-store were quoted at $3.75@$4 per 100 lb. Export demand was rather quiet at $3.50@$3.60 per 100 lb. f.a.s., for standard brands.

Prussiate of Soda—Importers have again reduced prices, owing to the lack of consuming interest. Spot material was quoted down to 18½c. per lb., with shipments around 18c.

Vegetable Oils

Linseed Oil—Demand has slackened somewhat and prices reflected this condition. Spot oil was quoted by leading refiners at 87c. per gal., carload basis, in barrels. January shipments held around 85c., with January-February at 84c. per gal. April shipments were quoted at 80c. per gal.

Cottonseed Oil—Prices continued to advance on the crude oil and during the next week 9¾c. per lb. for crude oil, f.o.b. mills, Southeast, was considered an inside price.

Chinawood Oil—The market during the past week was quite active. Quotations ranged around 14@14½c.

St. Louis Market Reflects Better Business Conditions

Chemical Prices Are Advanced and There Are Prospects for Further Increases in Many Lines

St. Louis, Mo., Jan. 1, 1923.

Prices have not weakened, but on the contrary have stiffened materially since our last report. Further important advances would not prove surprising, for the costs of production are advancing steadily. Prospects for the year are very bright and a feeling of optimism is prominent in all lines.

A slight firming up in the alkali market has been noticeable in this market during the last 2 weeks. No price changes of any note have taken place, but price shading and the mad scramble for business have been conspicuously absent. *Caustic soda* is being quoted at $4.25 per 100 lb. for the flake in 5-drum lots and $3.90 for the solid in like quantities. *Soda ash* is firm at $2.30 in bags and $2.40 in barrels in lots of five. *Sodium bicarbonate* has not changed in price for some time, and about the best that is being done is $2.40 per 100 lb. in 3- to 5-bbl. lots. *Sal soda* is firm at $1.65 per 100 lb. in 5-bbl. lots and has been holding this level for sometime.

Unusual Sulphuric Acid Demand

The heavy *mineral acid* market is in sound shape, surplus stocks having been diminished and the demand being unusually good. *Sulphuric acid* is leading the group and the demand this fall has been extraordinary. The *white arsenic* situation remains unchanged. There is still a very great scarcity of this material, and the only goods that seem to be available are the imported. The demand from the insecticide manufacturers is unusually heavy. There has been very little doing in *citric acid* during the past 2 weeks. *Carbon bisulphide, technical*, is rather slow, as this is the off season. The demand for *carbon tetrachloride* has been steady with a very firm market. The production of *copperas* has increased, but the demand has kept abreast so that there is practically no surplus. Prices remain firm and unchanged. Price quotations on *glycerine* remain the same as of our previous report—that is, 18½c. in drums. The market is not strong and dealers are expecting a decline in the near future. Contracts are being made on 3 months basis and 6 months basis with protection against decline, and in one or two instances a flat price of 18c. has been done on a 6-month contract without protection. *Sulphur* is slightly weaker and can be had at $1.90 per 100 lb. for commercial in bags. There is still a very broad movement in *zinc sulphate*, prices ruling at 3⅝c. in carload lots and 3⅞c.@4c. in less than carload lots, f.o.b. St. Louis.

Oils and Paint Materials

Linseed oil is holding very firm at $1@$1.02 per gal. in 1- to 4-bbl. lots, and 90@92c. in 5-bbl. lots or over. Future prices are firm due to unfavorable reports from the Argentine flaxseed fields. Not much contract business is being done at present. *Castor oil* is still holding at 13½c. in drums, with little prospect for any decline in the near future. *Turpentine* has slipped off slightly and is being quoted at 14c. in single barrels, $1.37 in 5-bbl. lots.

So far the expected rise in the *zinc oxide* price has not materialized, and the material is on a firm basis. A good volume of business is being done. No changes are reported for *whiting, blanc fixe* or *barytes*, but business is on the increase and manufacturers in this section report a waiting market.

A Seasonal Lull in the Chicago Market

A Good Outlook for the Year, However, Has Kept Prices at Fairly High Levels

CHICAGO, Ill., Jan. 5, 1923.

The chemical market has been very quiet for the past 2 weeks, with the industry reporting little business. Prices held firm, as it was obvious that it was not a question of price that was keeping the buyers out of the market. The outlook for this year is exceptionally fine, however, and all factors are expecting a prosperous year.

ALKALIS SELLING BELOW COST

The alkali market continued firm, with rumors of an advance to take place in the near future. Actual business was very light and spot quotations on *caustic soda* were unchanged at $3.50 per 100 lb. for the solid 76 per cent and $4.25 for the ground or flake. *Soda ash* was quiet and unchanged at $2.25 per 100 lb. for material in cooperage. *Caustic potash* moved only in a very small way at 7¼@7½c. per lb. for the 88-92 per cent material. Dealers claim that this price is lower than the present replacement cost.

Alums continued quiet and were unchanged in price. *Potash alum* in lump form was quoted at 4½@5c. per lb. and in powdered form at 5½@6c. *Sal ammoniac* was in a firm position, with spot supplies held at 8c. per lb. for the white granular. *Barium chloride* was unchanged in price, with the demand rather quiet. Prime white material was offered at $110 per ton. *Barium hydrate* was dull and supplies were available at 6¼c. per lb. in large casks. *White arsenic* continued very firm and was so scarce that a holder could get his own price. One or two small lots were offered at 17c. per lb. *Carbon tetrachloride* moved in a fair way and was very firm at 10½c. per lb. *Carbon bisulphide* was quoted in small or moderate lots for delivery from spot stock at 7½c. per lb.

OTHER PRICES WELL MAINTAINED

Copper sulphate was in rather limited request, but the price of 6c. per lb. was well maintained. *Formaldehyde* was firm at 17c. per lb. and supplies were reported as scanty. *Hexamethylenetetramine* was in fair request and supplies of foreign material were offered at 82@85c. per lb. *Furfural* was quoted at 25c. per lb. in thousand-pound lots. *Glycerine* was more or less unsteady and while the quoted price for the c.p. material in drums was 18½c., it was possible that good-sized business would have been taken at 18c.

LINSEED OIL AND TURPENTINE

Linseed oil was not moving in a large way, but the price was well maintained. The boiled oil in single-barrel lots was quoted today at 92c. per gal.

Turpentine was still considered high priced and dealers reported very little moving. The pure spirits was quoted at the close of today's market at $1.54 per gal. in single-drum lots.

Steel Market Enters Year With Better Prospects

Most Mills Comfortably Booked Ahead at Fairly Satisfactory Prices

PITTSBURGH, Jan. 5, 1923.

The complexion of the steel market changed decidedly during December and the outlook for a continuance of good business in the steel industry improved materially. December may be said to have made an unusual record in one respect, in that the turnover, in actual orders, was greater in the second half of the month than in the first half.

Thus the steel market has entered the new year with considerable momentum and naturally the prospect is that the buying will continue in very fair volume. Mill order books are in such shape, however, that a decided lull for a month would make no particular difference in the general situation. A number of mills had at the beginning of December not enough business to carry their operations fully through the month. Now these same mills are fully booked for more than a month. Not a few are comfortably booked for the whole quarter, while the Steel Corporation is almost wholly sold up for a longer period.

OUTPUT AT 75 PER CENT CAPACITY

Steel production continues at approximately the rate of the last 3 months of the old year, ingots being made at about 40,000,000 gross tons a year, or at about 75 per cent of capacity, finished rolled steel production being at about 30,000,000 tons a year. Production seems likely to increase rather than decrease in the next 2 or 3 months. The 40,000,000-ton rate compares with actual production in the whole of 1922 of about 34,000,000 tons, 19,000,000 tons in 1921 and 30,000,000 tons in both 1912 and 1913, the two greatest tonnage years before the war.

COKE AND PIG IRON

The Connellsville coke market has eased off a trifle in the past week, due to a practical cessation of buying by Eastern distributors for domestic consumption. Furnace coke is quotable at $8.50 @$9 against $9@$9.50 a week ago. Foundry coke remains at $9@$9.50 and there is somewhat more buying, although the market is still rather sluggish. Prices mentioned are for spot or prompt shipment.

Pig iron has been quiet in the past week. Foundry iron remains at $27 valley, to which it advanced after furnaces had made good sales, early in December, at $25 for first quarter. Basic, which went in several cases recently at $24.25 valley, cannot be bought at under $25 now and $26 might have to be paid. The stiffening is due not to increased inquiry but to the fact that steel interests that were offering basic iron have less inclination to part with it as their own consumption prospects are improved. Bessemer remains quiet at $27.50 valley.

Billets, sheet bars and slabs are quotable at $36.50, Pittsburgh or Youngstown. Very little has been done in billets and slabs, but there has been a very fair volume of covering in sheet bars as sales of sheets have been made.

Bars, shapes and plates are practically firm at 2c., concessions from this level being much less common than a month or two ago. Some large consumers of bars, expecting a concession on first quarter supplies, are now forced to pay the full price. Mills are best booked in bars, shapes coming next, while plates are a poor third.

Hoops are quoted at a general level of 2.90c., but orders that are at all attractive seem to be going at 2.75c., except for the lighter gages. Hot-rolled strips are at substantially the same level as hoops. Cold-rolled strips are firm at 4.50c. There is a very fair demand for both hot- and cold-rolled strips, attributable largely to activity in the automobile industry.

PIPE MILLS ACTIVE

Pipe mills are under about as much pressure as formerly for deliveries of butt weld pipe. Jobbers' stocks are practically exhausted and mills have no stocks. It is not unusual for mills to have a stock equal to a month's production, and normal jobbers' stocks would probably represent a larger tonnage still. The continued heavy pressure for deliveries is due to the open winter. Should consumption decrease for a time on account of weather, the slack would easily be taken up by partial replenishment of stocks. The outlook is for heavy consumption this season in oil country goods, as it is practically certain there will be a fair amount of drilling, and there is occasion for laying quite a good deal of pipe line, particularly from the Wyoming field. Tubular goods prices are very firmly maintained, merchant steel pipe being at 66 per cent basing discount.

The market for sheets is firm at 2.50c. for blue annealed, 3.35c. for black, 4.35c. for galvanized and 4.70@5c. for automobile sheets, depending chiefly on time of delivery.

Tin plate buying has been rather brisk in the past few weeks, the business being chiefly in definite orders, with specifications, for January and February delivery or for delivery over the quarter. There has not been much contracting for the half year. The market is very firm, on the basis of $4.75 per base box for 100-lb. cokes. Predictions are practically universal that this year will break all records in domestic consumption of tin plate.

Bookings in wire products, particularly nails, have been increasing and all producers are sold up for comfortable distances ahead. The majority of independents have advanced their prices $2 a ton, not so much with the idea of obtaining higher prices at once, but of protecting their order books from getting too full and enabling them later to get the higher prices by way of a delivery premium. The leading interest is not expected to modify its prices which are at 2.45c. for plain wire, $2.70 for wire nails and $2.20 for cement coated nails.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the America manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basi and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importanc to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages

Fullers earth, f.o.b mines	net ton	$16 00 –	$17 00
Fullers earth—imp., powd.	net ton	30 00 –	32 00
Fusel oil, ref., drums	gal.	3 55 –	4 05
Fusel oil, crude, drums	gal	2 30 –	2 40
Glaubers salt, wks., bags	100 lb.	1 20 –	1 40
Glaubers salt, imp., bags	100 lb.	1.00 –	1.25
Glycerine, c p., drums extra	lb.	.18½–	19
Glycerine, dynamite, drums	lb.	16 –	17
Iodine, resublimed	lb.	4 50 –	4 60
Iron oxide, red, casks	lb.	.12 –	.18
Lead:			
White, basic carbonate, dry, casks	lb.	.08 –	.08¼
White, in oil, kegs	lb.	.10½–	.12
Red, dry, casks	lb.	10½–	10¾
Red, in oil, kegs	lb.	12 –	14
Lead acetate, white crys., bbl	lb.	12 –	12½
Lead arsenate, powd., bbl	lb.	21 –	.22
Litharge, comm., casks	lb.	.09½–	10
Lithophone, bbl	lb	06½–	06¾
Magnesium carb., tech., bags	lb	07 –	07½
Methanol, 95%, bbl	gal	1.23 –	1 25
Methanol, 97%, bbl	gal.	1.25 –	1 27
Nickel salt, double, bbl.	lb.	.10 –	.10½
Nickel salts, single, bbl	lb.	.11 –	.11½
Phosgene		.60 –	75
Phosphorus, red, cases	lb.	.35 –	40
Phosphorus, yellow, cases	lb.	.30 –	35
Potassium bichromate, casks	lb.	.09½–	.10
Potassium bromide, gran., bbl	lb.	.18 –	.25
Potassium carbonate, 80-85%, calcined, casks	lb.	.05½–	05¾
Potassium chlorate, powd	lb.	07½–	08
Potassium cyanide, drums	lb	.47 –	.80
Potassium hydroxide (caustic potash) drums	100 lb.	6.50 –	6 75
Potassium iodide, cases	lb.	3.55 –	3 65
Potassium nitrate, bbl	lb.	.06½–	07
Potassium permanganate, drums	lb.	.16 –	16½
Potassium prussiate, red, casks	lb.	.90 –	95
Potassium prussiate, yellow, casks	lb.	.38 –	39
Salammoniac, white, gran., casks	lb	06½–	06¾
Gray, gran., casks	lb.	.08 –	08½
Salsoda, bbl	100 lb.	1.20 –	1 40
Salt cake (bulk)	ton	25.00 –	27 00
Soda ash, light, 58%, flat, bags, contract	100 lb.	1.60 –	1 67
Soda ash, light, basis, 48%, bags, contract, f o b wks.	100 lb.	1.20 –	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb	1.75 –	1 80
Soda ash, dense, bags, contract, basis 48%	100 lb.	1.17½ –	1.20
Soda ash, dense, in bags, resale	100 lb.	1.85 –	1 90
Soda, caustic, 76%, solid, drums, f.a.s.	100 lb.	3.50 –	3.75
Soda, caustic, 76%, solid, drums, contract	100 lb.	3.35	3.40
Soda, caustic, basis 60%, wks., contract	100 lb.	2.50 –	2 60
Soda, caustic, ground and flake, contracts	100 lb.	3.80 –	3.90
Soda, caustic, ground and flake, resale	100 lb.	4.00 –	4.15
Sodium acetate, works, bags	lb.	.06½–	07¼
Sodium bicarbonate, bbl	100 lb.	1 75 –	1.85
Sodium bichromate, casks	lb	07½–	.07¾
Sodium bisulphate (niter cake)	ton	6.00 –	7.00
Sodium bisulphite, powd., U S P, bbl	lb.	.04½–	.04¾
Sodium chlorate, kegs	lb.	06 –	.07
Sodium chloride	long ton	12.00 –	13.00
Sodium cyanide, cases	lb.	.19 –	.23
Sodium fluoride, bbl.	lb.	.09 –	.09½
Sodium hyposulphite, bbl	lb.	.03 –	.03¼
Sodium nitrite, casks	lb.	.08½–	.09
Sodium peroxide, powd., cases	lb.	.28 –	.30
Sodium phosphate, dibasic, bbl.	lb.	.03½–	.04
Sodium prussiate, yel. drums	lb.	.18½–	.20
Sodium silicate (40°, drums)	100 lb.	1.25 –	1.30
Sodium silicate (60°, drums)	100 lb.	2.25 –	2.40
Sodium sulphide, fused, 60-62% drums	lb.	.04½–	.04¾
Sodium sulphite, crys., bbl	lb.	.03½–	.03¾
Strontium nitrate, powd., bbl.	lb.	.09½–	.10
Sulphur chloride, yel drums	lb.	.04½–	.05
Sulphur, crude	ton	18.00 –	20.00
Sulphur dioxide, liquid, cyl.	lb.	.08 –	.08
Sulphur, flour, bbl	100 lb.	2.50 –	3.15
Sulphur, roll, bbl	100 lb.	2.15 –	2.20
Talc—imported, bags	ton	30.00 –	40.00
Talc—domestic powd., bags	ton	18.00 –	25.00

Tin bichloride, bbl	lb.	$.10½–	$.10
Tin oxide, bbl	lb.	.45 –	.47
Zinc carbonate, bags	lb.	14 –	.14
Zinc chloride, gran, bbl	lb.	.07 –	.07
Zinc cyanide, drums	lb.	.42 –	.44
Zinc oxide, XX, bbl.	lb.	.07½–	.08
Zinc sulphate, bbl.	100 lb.	2.75 –	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb.	$ .95 –	$1.00
Alpha-naphthol, ref., bbl.	lb.	1.05 –	1.10
Alpha-naphthylamine, bbl.	lb.	.28 –	.30
Aniline oil, drums	lb.	.16½–	.17
Aniline salts, bbl	lb	.24 –	.25
Anthracene, 80%, drums	lb.	.75 –	1.00
Anthracene, 80%, imp., drums, duty paid	lb.	65 –	.70
Anthraquinone, 25%, paste, drums	lb.	.70 –	.75
Benzaldehyde U.S.P., carboys	lb.	1.35 –	1.40
Benzene, pure, water-white drums	gal.	.30 –	.35
Benzene, 90%, drums	gal.	.28 –	.32
Benzene, 90%, drums, resale.	gal.	.37 –	.40
Benzidine base, bbl	lb.	.85 –	.90
Benzidine sulphate, bbl	lb.	.75 –	.80
Benzoic acid, U S P., kegs	lb.	70 –	.75
Benzoate of soda, U S P., bbl.	lb.	.57 –	.65
Benzyl chloride, 95-97%, ref., drums	lb.	.25 –	.27
Benzyl chloride, tech., drums	lb.	.20 –	.23
Beta-naphthol, subl., bbl	lb.	.55 –	.60
Beta-naphthol, tech., bbl	lb.	.25 –	.26
Beta-naphthylamine, tech.	lb.	1.00 –	1.25
Carbazol, bbl.	lb.	.75 –	.90
Cresol, U.S P., drums	lb.	.14 –	.20
Ortho-cresol, drums	lb	.18 –	.22
Cresylic acid, 97-99%, drums.	gal.	.60 –	.65
95-97%, drums	gal.	.55 –	.58
97%, resale, drums	gal.	1.00 –	1.05
Dichlorbenzene, drums	lb.	.07 –	.09
Diethylaniline, drums	lb.	.50 –	.60
Dimethylaniline, drums	lb.	.39 –	.41
Dinitrobenzene, bbl	lb.	.20 –	.22
Dinitroclorbenzene, bbl	lb.	.22 –	.23
Dinitronaphthalene, bbl.	lb.	.30 –	.32
Dinitrophenol, bbl	lb.	.34 –	.36
Dinitrotoluene, bbl	lb	22 –	.24
Dip oil, 25%, drums	gal.	.25 –	.30
Diphenylamine, bbl	lb.	.54 –	.56
H-acid, bbl.	lb.	.75 –	.80
Meta-phenylenediamine, bbl.	lb.	.95 –	1.00
Michlers ketone, bbl	lb.	3 75 –	3.85
Monochlorbenzene, drums	lb.	.08 –	.10
Monoethylaniline, drums	lb.	.95 –	1.10
Naphthalene, crushed, bbl.	lb.	.05½–	.06
Naphthalene, flake, bbl.	lb.	.06 –	.06½
Naphthalene, balls, bbl.	lb.	.06½–	.07
Naphthionate of soda, bbl	lb.	.58 –	.65
Naphthionic acid, crude, bbl	lb.	.60 –	.65
Nitrobenzene, drums	lb.	.10 –	.12
Nitro-naphthalene, bbl	lb.	.30 –	.35
Nitro-toluene, drums	lb.	.15 –	.17
N-W acid, bbl.	lb.	1.20 –	1.30
Ortho-amidophenol, kegs	lb.	2.25 –	2.30
Ortho-dichlorbenzene, drums	lb.	.17 –	.20
Ortho-nitrophenol, bbl	lb.	.85 –	.90
Ortho-nitrotoluene, drums	lb.	.12½–	.14
Ortho-toluidine, bbl	lb.	.14 –	.16
Para-amidophenol, base, kegs	lb.	1.15 –	1.20
Para-amidophenol, HCl, kegs	lb.	1.20 –	1.25
Para-dichlorbenzene, bbl.	lb.	.17 –	.20
Paranitraniline, bbl	lb.	.75 –	.80
Para-nitrotoluene, bbl.	lb.	.55 –	.65
Para-phenylenediamine, bbl.	lb.	1.50 –	1.55
Para-toluidine, bbl.	lb.	.85 –	.90
Phthalic anhydride, bbl.	lb.	.40 –	.50
Phenol, U.S.P., drums	lb.	.34 –	.35
Picric acid, bbl.	lb.	.20 –	.22
Pyridine, dom., drums	gal.	1.60 –	1.75
Pyridine, imp., drums	gal.	1.40 –	1.60
Resorcinol, tech., kegs	lb.	1.50 –	1.55
Resorcinol, pure, kegs	lb.	2.00 –	2.10
R-salt, bbl.	lb.	.55 –	.60
Salicylic acid, tech., bbl	lb.	.35 –	.37
Salicylic acid, U.S.P., bbl	lb.	.40 –	.42
Solvent naphtha, water-white, drums	gal.	.37 –	.40
Crude, drums	gal.	.22 –	.24
Sulphanilic acid, crude, bbl	lb.	.20 –	.22
Thiocarbanilide, kegs	lb.	.35 –	.38
Toluidine, kegs	lb.	1.20 –	1.30
Toluidine, mixed, kegs	lb.	.30 –	.35
Toluene, tank cars	gal.	.35 –	.37
Toluene, drums	gal.	.40 –	.43
Xylidines, drums	lb.	.40 –	.45
Xylene, pure, drums	gal.	.45 –	.50
Xylene, pure tanks	gal.	.45 –	
Xylene, com., drums	gal.	.40 –	.42
Xylene, com., tanks	gal.	.38 –	

Naval Stores

Rosin B-D, bbl.	280 lb.	$6.25 –	....
Rosin E-I, bbl.	280 lb.	6.40 –	....
Rosin K-N, bbl.	280 lb.	6.60 –	$6.85
Rosin W.G.-W.W., bbl.	280 lb.	7.75 –	8.25
Wood rosin, bbl.	280 lb.	6.25 –	
Turpentine, spirits of, bbl.	gal.	1.54 –	1.55
Wood, steam dist., bbl.	gal.	1.35 –	
Wood, dest. dist., bbl.	gal.	1.25 –	
Pine tar pitch, bbl.	200 lb.	.... –	6.00
Tar, kiln burned, bbl.	500 lb.	.... –	12.50
Retort tar, bbl.	500 lb.	.... –	11.00
Rosin oil, first run, bbl.	gal.	.43 –	
Rosin oil, second run, bbl.	gal.	.47 –	
Rosin oil, third run, bbl.	gal.	.53 –	....
Pine oil, steam dist.	gal.	.... –	.90
Pine oil, pure, dest. dist.	gal.	.... –	.85
Pine tar oil, ref.	gal.	.... –	.46
Pine tar oil, crude, tanks f.o.b. Jacksonville, Fla.	gal.	.... –	.35
Pine tar oil, double ref., bbl.	gal.	.... –	.75
Pine tar, ref., thin, bbl.	gal.	.... –	.25
Pinewood creosote, ref., bbl.	gal.	.... –	.52

Vegetable Oils

Castor oil, No. 3, bbl.	lb.	$.11¾ –	$.12¼
Castor oil, AA, bbl.	lb.	.12¼ –	.12¾
Chinawood oil, bbl.	lb.	.14 –	.14½
Coconut oil, Ceylon, bbl.	lb.	.09¼ –	.09½
Coconut oil, Cochin, bbl.	lb.	.09½ –	.09¾
Corn oil, crude, bbl.	lb.	.11 –	.11½
Cottonseed oil, crude (f.o.b. mill), tanks.	lb.	.09¼ –	
Summer yellow, bbl.	lb.	.11 –	.11¼
Winter yellow, bbl.	lb.	.11½ –	.12
Linseed oil, raw, car lots, bbl.	gal.	.87 –	.88
Raw, tank cars (dom.)	gal.	.84 –	.85
Boiled, 5-bbl. lots (dom.)	gal.	.89 –	.90
Olive oil, denatured, bbl.	gal.	1.05 –	1.12
Palm, Lagos, casks	lb.	.07¾ –	.08
Palm kernel, bbl.	lb.	.08¼ –	.08½
Peanut oil, crude, tanks (mill)	lb.	.12½ –	.12¾
Peanut oil, refined, bbl.	lb.	.15½ –	.16
Rapeseed oil, refined, bbl.	gal.	.85 –	.86
Rapeseed oil, blown, bbl.	gal.	.90 –	.91
Soya bean (Manchurian), bbl.	lb.	.11½ –	
Tank, f.o.b. Pacific coast	lb.	.09¼ –	.09½

Fish Oils

Menhaden, light pressed, bbl.	gal.	$0.60 –	
White bleached, bbl.	gal.	.64 –	.65
Blown, bbl.	gal.	.68 –	.69
Whale No. 1 crude, tanks, coast	lb.	.06 –	.06½

Dye & Tanning Materials

Divi-divi, bags	ton	$38.00 –	$39.00
Fustic, sticks	ton	30.00 –	35.00
Fustic, chips, bags	lb.	.04	.05
Logwood, sticks	ton	28.00 –	30.00
Logwood, chips, bags	lb.	.02½ –	.03½
Sumac, leaves, Sicily, bags	ton	65.00 –	
Sumac, ground, bags	ton	55.00 –	60.00
Sumac, domestic, bags	ton	35.00 –	
Tapioca flour, bags	lb.	.03½ –	.05

EXTRACTS

Archil, conc., bbl.	lb.	$0.18 –	$0.20
Chestnut, 25% tannin, tanks	lb.	.02 –	.03
Divi-divi, 25% tannin, bbl.	lb.	.04 –	.05
Fustic, crystals, bbl.	lb.	.20 –	.22
Fustic, liquid, 42°, bbl.	lb.	.08 –	.09
Gambier, liq., 25% tannin, bbl.	lb.	.08 –	.09
Hematine crys., bbl.	lb.	.14 –	.18
Hemlock, 25% tannin, bbl.	lb.	.04 –	.05
Hypernic, solid, drums	lb.	.24 –	.26
Hypernic, liquid, 51°, bbl.	lb.	.14 –	.17
Logwood, crys., bbl.	lb.	.19 –	.20
Logwood, liq., 51°, bbl.	lb.	.09 –	.10
Quebracho, solid, 65% tannin, bbl.	lb.	.04½ –	.05
Sumac, dom., 51°, bbl.	lb.	.06½ –	.07

Waxes

Bayberry, bbl.	lb.	$0.29 –	$0.30
Beeswax, refined, dark, bags	lb.	.30 –	.32
Beeswax, refined, light, bags	lb.	.34 –	.35
Beeswax, pure white, cases	lb.	.39 –	.40
Candelilla, bags	lb.	.34	.35
Carnauba, No. 1, bags	lb.	.38 –	.40
No. 2, North Country, bags	lb.	.23 –	.24
No. 3, North Country, bags	lb.	.17 –	.17½
Japan, cases	lb.	.15 –	.15½
Montan, crude, bags	lb.	.03½ –	.04
Paraffine, crude, match, 105-110 m.p.	lb.	.04 –	.04½
Crude, scale 124-126 m.p., bags	lb.	.02½ –	.02¾
Ref., 118-120 m.p., bags	lb.	.03¼ –	.03½
Ref., 125 m.p., bags	lb.	.03½ –	.03¾
Ref., 128-130 m.p., bags	lb.	.04 –	.04¼
Ref., 133-135 m.p., bags	lb.	.04½ –	.04¾
Ref., 135-137 m.p., bags	lb.	.05 –	.05¼
Stearic acid, sgle pressed, bags	lb.	.10 –	.10¼
Double pressed, bags	lb.	.10½ –	.10¾
Triple pressed, bags	lb.	.11 –	.11½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3.20 –	$3.25
F.a.s. double bags	100 lb.	3.60 –	3.75
Blood, dried, bulk	unit	4.60 –	....
Bone, raw, 3 and 50, ground	ton	30.00 –	35.00
Fish scrap, dom., dried, wks.	unit	5.00 –	5.10
Nitrate of soda, bags	100 lb.	2.60 –	2.65
Tankage, high grade, f.o.b. Chicago	unit	4.60 –	4.65

Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	$3.50 –	$4.00
Tennessee, 78-80%	ton	7.00 –	8.00
Potassium muriate, 80%, bags	ton	35.55 –	38.25
Potassium sulphate, bags	unit	1.00 –	....

Crude Rubber

Para—Upriver fine	lb.	$0.25½ –	$0.25¾
Upriver coarse	lb.	.18¼ –	.18½
Upriver caucho ball	lb.	.20½ –	.20¾
Plantation—First latex crepe	lb.	.28½ –	.29
Ribbed smoked sheets	lb.	.28½ –	.29
Brown crepe, thin, clean	lb.	.23 –	.23½
Amber crepe No. 1	lb.	.23 –	.23½

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec	sh. ton	$450.00 –	$550.00
Asbestos, shingle, f.o.b., Quebec	sh. ton	60.00 –	80.00
Asbestos, cement, f.o.b., Quebec	sh. ton	15.00 –	17.00
Barytes, grd., white, f.o.b. mills, bbl.	net ton	16.00 –	20.00
Barytes, grd., off-color, f.o.b. mills bulk	net ton	13.00 –	21.00
Barytes, floated, f.o.b. St. Louis, bbl.	net ton	24.00 –	28.00
Barytes, crude f.o.b. mines, bulk	net ton	8.00 –	9.00
Casein, bbl., tech.	lb.	.12 –	.14
China clay (kaolin) crude, f.o.b. Ga.	net ton	7.00 –	9.00
Washed, f.o.b. Ga.	net ton	8.00 –	9.00
Powd., f.o.b. Ga.	net ton	14.00	20.00
Crude f.o.b. Va.	net ton	8.00 –	12.00
Ground, f.o.b. Va.	net ton	13.00 –	20.00
Imp., lump, bulk	net ton	14.00 –	20.00
Imp., powd.	net ton	40.00 –	45.00
Feldspar, No. 1 pottery	long ton	6.00 –	7.00
No. 2 pottery	long ton	5.00 –	5.50
No. 1 soap	long ton	7.00 –	7.50
No. 1 Canadian, f.o.b. mill	long ton	20.00 –	21.00
Graphite, Ceylon, lump, first quality, bbl.	lb.	.05 –	.05½
Ceylon, chip, bbl.	lb.	.04 –	.04½
High grade amorphous crude	ton	35.00 –	50.00
Gum arabic, amber, sorts, bags	lb.	.15 –	.16
Gum tragacanth, sorts, bags	lb.	.50 –	.60
No. 1, bags	lb.	1.75 –	1.80
Kieselguhr, f.o.b. Cal.	ton	40.00 –	42.00
F.o.b. N.Y.	ton	50.00 –	55.00
Magnesite, crude, f.o.b. Cal.	ton	14.00 –	15.00
Pumice stone, imp., casks	lb.	.03 –	.05½
Dom., lump, bbl.	lb.	.05 –	.05½
Dom., ground, bbl.	lb.	.06 –	.07
Shellac, orange fine, bags	lb.	.74 –	.75
Orange superfine, bags	lb.	.76 –	.77
A. C. garnet, bags	lb.	.75 –	.77
T. N., bags	lb.	.72 –	.73
Silica, glass sand, f.o.b. Ind.	ton	2.00 –	2.50
Silica, sand blast, f.o.b. Ind.	ton	2.50	5.00
Silica, amorphous, 250-mesh, f.o.b. Ill.	ton	17.00 –	17.50
Silica, bldg. sand, f.o.b. Pa.	ton	2.00 –	2.75
Soapstone, coarse, f.o.b. Vt., bags	ton	7.00 –	8.00
Talc, 200 mesh, f.o.b., Vt., bags	ton	6.50 –	9.00
Talc, 200 mesh, f.o.b. Ga., bags	ton	7.00 –	9.00
Talc, 200 mesh, f.o.b. Los Angeles, bags	ton	16.00 –	20.00

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	ton	$45–50
Chrome brick, f.o.b. Eastern shipping points	ton	50–52
Chrome cement, 40-50% Cr_2O_3	ton	23–27
40-45% Cr_2O_3, sacks, f.o.b. Eastern shipping points	ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Ky. wks.	1,000	40–46
2nd. quality, 9-in. shapes, f.o.b. wks.	1,000	36–41
Magnesite brick, 9-in. straight (f.o.b. wks.)	ton	65–68
9-in. arches, wedges and keys	ton	80–85
Scraps and splits	ton	85
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48–50
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	48–50
F.o.b. Mt. Union, Pa.	1,000	42–44
Silicon carbide refract. brick, 9-in.	1,000	1,100.00

Ferro-Alloys

Ferrotitanium, 15-18% f.o.b. Niagara Falls, N.Y.	ton	$200.00 –	$225.00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	.11 –	.11½
4-6% C	lb.	.11½ –	.12
Ferromanganese, 78-82% Mn, Atlantic seabd. duty paid	gr. ton	100.00 –	105.00
Spiegeleisen, 19-21% Mn.	gr. ton	35.00 –	37.00

Financial. Construction and Manufacturers' News

Construction and Operation

Alabama

SYLACAUGA—The Sylacauga Fertilizer Co has completed plans for the immediate erection of a new 1-story plant, 30x100 ft., for the production of commercial fertilizer. Another unit of like size will be constructed as soon as the first building has been completed.

HOLT—The Central Foundry Co has commenced enlargements in its local plant, including remodeling work. It is proposed to convert the structure into a hand-molding shop for the manufacture of pipe and fittings. It has been closed for about a year past. Headquarters of the company are at 41 East 42nd St., New York.

California

SAN FRANCISCO—The Los Angeles Soap Co., 633 East 1st St., Los Angeles, manufacturer of soaps, washing powders, refined cottonseed oils, etc., will soon take bids for the erection of its proposed 2-story and basement plant at 2nd and Brannan Sts., San Francisco, estimated to cost $80,000, including equipment. W. H. Crim, Jr., 425 Kearny St., San Francisco, is architect.

LOS ANGELES—The California Enameling Co. will soon break ground for the construction of a new 1-story plant at 51st St. and Santa Fe Ave., 300x600 ft., for the manufacture of enameled products. Hamm & Grant, Ferguson Bldg., are architects.

SEBASTOPOL—The Western Apple Vinegar Co., McKinley St., has acquired property adjoining its plant and plans for the erection of a new dehydrator works. Bids will be asked at an early date.

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg., San Francisco, has increased the size of its proposed new refinery at Los Angeles Harbor from 2- to 3-story, of size 250x305 ft. A general contract for erection will soon be let. The complete plant will cost in excess of $1,200,000, including machinery. Albert C. Martin, Higgins Bldg., Los Angeles, is architect.

LOS ANGELES—The Shell Oil Co., 313 Sansome St., San Francisco, has leased a tract of land totaling about 5 acres on Mormon Island, San Pedro, as a site for the construction of a new storage and distributing plant. Plans will be prepared at an early date. The estimated cost is reported in excess of $90,000, with equipment.

Connecticut

HARTFORD—The Lotz Asbestos Co., 60 Prospect St., manufacturer of special cements, asbestos specialties, etc., has acquired a 2-story factory on site 100x130 ft., at 479 Windsor St., for a new plant for increased production. The structure will be improved and enlarged with the construction of two additional stories. Early occupancy is planned.

BERLIN—The Hall-Spiers Brick Co., recently organized with a capital of $75,000, will succeed the company of the same name operating a local plant. Extensions are planned, including the installation of equipment for oil-burning for kiln service. F. M. Hall is president, and Paul H. Spiers, vice-president and secretary.

Florida

OCALA—The Loncala Phosphate Co., P.O. Box 471, is planning for the installation of brick-manufacturing equipment at its plant. Inquiries are being made for hand-power or gasoline engine-operated apparatus.

Georgia

ATLANTA—The United Paper Co., manufacturer of fruit-wrapping and other paper products, has tentative plans under consideration for the erection of a new 5-story building on local site, to cost about $200,000.

Illinois

CHICAGO—The Enamel Steel Sign Co., 190 North State St., has completed plans and is taking bids for the erection of a 1- and 2-story plant on West Ravenswood Ave., 100x160 ft. Arthur H. Knox, 7 West Madison St., is architect. Manly Simmons is president.

CHICAGO—Gutman & Co., Webster Ave. and Dominick St., leather tanners, have plans nearing completion for the erection of additions to their plant, including a main 1-story extension, 40x160 ft., for general production; 1- to 3-story beam house, 37x115 ft.; and carpenter and woodworking shop, 40x66 ft. The structures are estimated to cost $50,000.

CHICAGO—The Patterson-Sargent Co., 2025 Lumber St., manufacturer of varnishes, paints, etc., with headquarters at Cleveland, O., has completed foundations and will proceed the superstructure for its new branch plant at Seward and Lumber Sts., estimated to cost about $175,000. A. E. Fenn is local manager.

Indiana

EAST CHICAGO—The Pressed Steel Mfg. Co., 20 West Jackson Blvd., Chicago, Ill., has plans nearing completion for the erection of a new plant at East Chicago, to be 2-story, estimated to cost in excess of $100,000. Frank D. Chase, Inc., 645 North Michigan Ave., Chicago, is architect and engineer. Walter P. Murphy is president.

Kentucky

SCOTTSVILLE—The Massey Oil & Refining Co., recently organized, will succeed to the plant and business of the Massey Refining Co. Extensions and improvements are planned in the present refinery. W. E. Massey, Louisville, is president.

Louisiana

NEW ORLEANS—The Prest-O-Lite Co., Indianapolis, Ind., manufacturer of acetylene apparatus, has awarded a contract to J. V. and R. T. Burkes, New Orleans, for the erection of the initial buildings for its proposed new local plant. A group of ten structures will be erected, estimated to cost in excess of $150,000 with equipment. The company is operated by the Union Carbide Co., 30 East 42nd St., New York, N. Y.

MONROE—The Monroe-Louisiana Carbon Co., DeKalb and Zepp Sts., St. Louis, Mo., has commissioned Chauncey Matlock, 949 Broadway, New York, consulting engineer, to prepare plans for its proposed new plant at Ladel, near Monroe, to have an initial daily output of about 5,000 lb. of carbon black. The majority of equipment will be electrically operated. The buildings to be erected at the present time will cost about $100,000, and this appropriation will be increased at a later date.

Maryland

BALTIMORE—The Crown Oil & Wax Co., Pratt and 8th Sts., has filed plans for the erection of a 1-story addition, 45x88 ft. The contract for construction has been let to Charles E. Ehrman & Sons, Baltimore.

DUNKIRK—The Dashiell Mining & Refining Co. is planning for extensive developments on local rare earth deposits. A plant will be installed with conveyor system and other mechanical apparatus. B. J. Dashiell, Baltimore, is consulting engineer for the company.

Michigan

MONROE—The Monroe Paper Products Co. has commenced the erection of a new addition to its plant, 75x225 ft., to be equipped for the employment of about 50 operatives.

GRAND LODGE—The Briggs Clay & Mfg. Co., has tentative plans under consideration for the rebuilding of the portion of its plant, destroyed by fire, Dec. 20, with loss reported at $17,000.

CALUMET—The Calumet & Hecla Co., operating copper mining and smelting properties, has work under way on a plant for the treatment of Tamarack conglomerate sands for local service.

CHEBOYGAN—Fire, Dec. 22, destroyed a portion of the foundry of the Cheboygan Brass Foundry Co., with loss estimated at about $12,000. It is planned to rebuild.

PONTIAC—The Pontiac Varnish Co., has plans under way for the erection of a new plant addition to cost about $25,000. C. H. Hutchins is president.

NEW BALTIMORE—Charles Reimold and R. A. Waterbury, Mt. Clemens, Mich., are organizing a company to construct and operate a local plant for the manufacture of brick and other burned clay products. Options have been secured on a tract of clay property for the plant site.

DETROIT—Robert Finn, 622 McKeachey Bldg., architect, has plans in progress for a new foundry, 1-story, 50x140 ft., estimated to cost about $15,000, to be erected on local site. The name of the owner is temporarily withheld.

ST. JOSEPH—The local plant of the Mullen Brothers Paper Co. has been acquired at a sale in bankruptcy by Francis Hughes, Chicago, Ill., and associates, for a consideration of about $70,000. The new owners are said to be planning for a reorganization of the company and the operation of the mill, including proposed extensions and improvements.

Minnesota

HIBBING—The Water & Light Department, D. D. Haley, secretary, has awarded a general contract to the Phelps Brake Co., Hibbing, for the erection of a 1-story and basement addition to the municipal artificial gas plant, 35x66 ft., estimated to cost about $90,000. Charles Foster, Sellwood Bldg., Duluth, Minn., is engineer.

Mississippi

MOSS POINT—The Southern Paper Co. has plans nearing completion for the erection of a new pulp and paper mill at its local plant, with daily output of about 120 tons, equally divided between pulp and paper. It is expected to call for bids at an early date. George F. Hardy, 309 Broadway, New York, N. Y., is engineer. J. L. Dantzler is president.

Missouri

KANSAS CITY—The Schreiber Flour & Cereal Co. has tentative plans under consideration for the rebuilding of the portion of its 5-story mill, destroyed by fire, Dec. 15, with loss approximating $125,000, including equipment.

New Jersey

NEWARK—The Department of Streets and Public Improvements will install a complete chemical laboratory in the new building to be constructed for the Bureau of Water at Cedar Grove. It will cost about $20,000.

NEWARK—The Board of Education, City Hall, is considering the installation of additional equipment in the chemistry department at the new Seymour Vocational School, Sussex Ave. It is also planned to install foundry apparatus and other equipment in the different departments.

Ohio

UTICA—The Licking Window Glass Co. has completed plans and will soon break ground for the construction of a 1-story addition, 148x160 ft., estimated to cost about $35,000. It will be equipped for the production of plate glass. The Truscon Engineering Co., Ferris Bldg., Columbus, O., is engineer in charge. H. H. S. McCann is secretary.

SHELBY—The Ohio Seamless Tube Co. will soon commence the construction of a plant addition, 100x280 ft., to be used primarily for the production of cold drawn tubing. Other plant extensions are contemplated. The work is estimated to cost approximately $200,000, including machinery.

Oklahoma

CHICKASHA—The Chamber of Commerce, J. W. Comer, secretary, is perfecting plans for the construction and operation of a local plant for the manufacture of glass products. It is proposed to organize a company to carry out the project. Plans are also being discussed for the establishment of a local mill for the manufacture of corrugated paper products.

PERRY—The Garber Oil Refining Co. is said to have plans under way for the construction of an addition to its local refinery. E. A. Hutcheson is general manager.

Pennsylvania

JEANNETTE—The American Window Glass Co., Farmers' Bank Bldg., Pittsburgh, has arranged an appropriation of approximately $250,000, for the proposed addition to its local plant, on which work has been commenced. A general contract has been awarded to the Bollinger-Andrews Co., Empire Bldg., Pittsburgh. William L. Monroe is president.

CHESTER—The Stauffer Chemical Co., 624 California Ave., San Francisco, Calif., has awarded a contract to the Chester Construction & Contracting Co., Chester, for the erection of the first unit of its proposed new plant on Front St., Trainer, near Chester, estimated to cost approximately $165,000.

WEST READING—The A. Wilhem Co., manufacturer of enamels, paints, etc., has tentative plans under consideration for the rebuilding of its local plant, destroyed by fire Dec. 24, with loss reported at $14,000.

PITTSBURGH—The Vitro Mfg. Co., Bessemer Bldg., manufacturer of enamels and kindred products, has filed plans for the construction of its proposed 1-story plant on Oliffe St., and will commence immediate erection. It is estimated to cost about $10,000.

PHILADELPHIA—The Quaker City Japanning & Enameling Co. has leased a floor in the building at Buttonwood and 10th Sts., for the establishment of a local plant.

CREIGHTON—The Pittsburgh Plate Glass Co., Frick Bldg., Pittsburgh, is perfecting plans for the construction of a local plant, to be equipped primarily for the manufacture of plate glass products for automobile service. It will have a capacity of more than 15,000,000 ft. per year, and is estimated to cost in excess of $200,000

LOWER GWYNEDD—The American Chemical Paint Co., 1126 South 11th St., Philadelphia, is completing plans and will take bids during January for the construction of a new plant here, on Brookside Ave J. Harvey Gravell is president.

PHILADELPHIA—A. Waxman & Co, 121 North 3rd St, glass products, has acquired adjoining property, and a 4-story factory in the immediate vicinity at 417-21 North Orianna St., 50x78 ft., for a consideration of about $[illegible]5,000, for proposed expansion

Tennessee

KNOXVILLE—The Cherokee Brick Co, recently organized, has acquired a tract of property in the Chestnut Ridge section, comprising about 20 acres of land, as a site for a new plant for the manufacture of face brick and other burned clay products. The initial works will have a capacity of about 40,000 bricks per day, and is estimated to cost in excess of $125,000 J. Albert Robbins is president, and E C. Wright, secretary.

MEMPHIS—The Board of Public Works will commence the immediate installation of a filtration plant in connection with extensions and improvements in the municipal waterworks, to cost close to $1,500,000.

Texas

FERRIS—The Globe Pressed Brick Co is planning for the rebuilding of the portion of its plant, destroyed by fire Dec. 19. An official estimate of loss has not been made.

Virginia

HOPEWELL—The Stamsocott Co. Inc, manufacturer of pulp and paper products, has work under way on enlargements in its plant, for considerable increase in capacity. The present working force of 350 men will be materially increased in the near future.

HOPEWELL—The Hummel-Ross Fibre Corp. is completing the erection of a new mill for the production of kraft paper, with daily capacity of about 50 tons, and plans to place the unit in service at an early date. The output at the pulp mill, on adjoining site, will be increased from 50 to 100 tons in the near future.

Washington

SEATTLE—The Concrete Pipe Co. is planning for the installation of a testing laboratory in a new 1-story and basement building, for which plans are now being prepared. A. H. Albertson, Henry Bldg., is architect.

TACOMA—Fire recently destroyed a portion of the plant of the Continental Pipe Co., 1612 Center St., with loss estimated at approximately $75,000. The plant has been operated under lease by the Washington Wood Products Co. It is planned to rebuild.

West Virginia

WHEELING—The B. & M. Metal Rolling Mill, 36th and McCulloch Sts., has perfected plans for the operation of a local plant for the manufacture of bronze rods and kindred specialties. It is proposed to develop a daily output of about 25 tons. W. J. Broddock is president.

Wisconsin

MILWAUKEE—The Rickertron Mineral Paint Co., South Bay St., has preliminary plans in preparation for the construction of a new 1-story and basement plant, 63x70 ft., on Wilcox St., to cost approximately $25,000. The Birkholz Engineering Co., 290 3rd St., is architect and engineer.

Industrial Developments

GLASS—The American Window Glass Co, Pittsburgh, Pa, is advancing production at its plants, with employment of additional workers. During 4 weeks near the close of last year, 567 carloads of window glass were shipped, establishing a new high record.

The Republic Glass Co., Monroe, Mich., is arranging for the immediate operation of its new local plant, recently completed at a cost of about $100,000, and will specialize in the manufacture of lenses and kindred high-grade glassware A full working force will be employed. M. M. Llera is president, and W. N. Mathews, vice-president and general manager.

CERAMIC The Hopewell China Corp. is planning for increased production at its pottery, including the installation of 2 new decorating kilns. The present equipment comprises 7 general ware and 6 decorating kilns, with total output of approximately 12,000 doz pieces per week The working force of 225 employees will be increased at an early date.

Practically all of the general ware potteries at East Liverpool, O, have resumed production, following the close of the operatives' strike, under full capacity schedule. It is said that orders received have booked a number of plants for the entire year to come

Brick-manufacturing plants in the Birmingham, Ala., district are all running on a full time schedule, with regular working forces, and a record production is expected during 1923.

The Metropolitan Paving Brick Co, Canton, O., is operating at full capacity at all of its plants, and it is expected to maintain this schedule for a number of weeks to come

The Chelsea China Co., New Cumberland, W Va., has resumed operations at its plant after a shut down of a number of weeks, and plans to develop maximum output in the line of hotel ware. A number of improvements are planned to facilitate operations.

The Corning Brick, Terra Cotta & Tile Works, Corning, N. Y., is increasing production of brick and terra cotta Employment is being given to close to 45 per cent more men than at this time a year ago, with early extensions contemplated in the working force

The Canton Brick & Fireproofing Co., Canton, O., is advancing operations at its plant and expects to develop capacity, with full working force.

The Alton Brick Co, Alton, Ill., is arranging for the early resumption of production at the former plant of the Banner Clay Works, Edwardsville, Ill., recently acquired. Extensions and improvements will be made, including the installation of additional equipment.

The What Cheer Clay Products Co., What Cheer, Ia., will operate under maximum output, following the completion of additions and improvements. It is expected to develop a capacity of close to 35,000 tons of material per annum.

IRON AND STEEL—The Marietta Furnace, Marietta, Pa., has resumed operations after a shut down of about 2 years, giving employment to about 100 men. It is expected to maintain production for an indefinite period.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., has resumed production at its finishing mills, following a brief curtailment during the holidays. The plant will run on a double turn under maximum operating schedule. The Fairfield plate mill of the company is running full, and has orders on hand to insure full capacity for a number of weeks to come. The third blast furnace at Bessemer, Ala., has been blown in on foundry iron, and a fourth unit will be placed in service at an early date. All six furnaces of the company at Ensley are in blast.

The Thomas Iron Co., Hokendauqua, Pa., is planning to blow in its local blast furnace about Jan. 15. A full working force will be employed under a capacity schedule.

The Gulf States Steel Co., Birmingham, Ala., is arranging to place its finishing mills on a double turn at an early date.

The Glasgow Iron Co., Pottstown, Pa., has placed its puddle mill in operation after an idle period dating back to 1918. A number of improvements have been made in the plant. It is expected to maintain production for an indefinite period. The universal mill and plate mill of the company are now in service on full turn.

The Interstate Iron & Steel Co., Chicago, Ill., is maintaining production at its alloy steel mills at close to capacity, with employment of regular working force.

The United States Steel Corp., Pittsburgh, Pa., is operating at its different plants at about 83 per cent of normal, the highest rate of production throughout 1922.

The Reading Iron Co., Reading, Pa., is running full at its plate mill and one of its puddle mills, and plans to maintain this basis for some time to come. The 8 plants of the company in neighboring sections are also on full turn.

Steel mills in the Chicago, Ill., district are operating on a basis of 75 to 80 per cent of normal, with prospects for early increase.

The Carpenter Steel Co., Reading, Pa., is maintaining full operations at its plant and is said to have advance orders to insure this basis for some time to come.

METALS—The Hoover Steel Ball Co., Chelsea, Mich, is planning for the early resumption of operations at its local plant, which has been closed down since late in 1920.

The Utah Copper Co., Salt Lake City, Utah, has placed another unit in operation at its new Magna mill, making 8 sections now in service. Other units are in the course of construction and will be placed in operation as soon as completed, or on the basis of 2 units a month. The mill will consist of 12 units.

The Chino Copper Co, Santa Rita, N. M., is maintaining close to normal operations at its local properties and an average of 600 tons of concentrates are being sent to the mill daily. The mill is running on a similar production schedule of 600 tons per day.

Pipe foundries in the vicinity of Birmingham, Ala., are running at capacity and a number of plants are arranging for immediate expansion. The Birmingham Machine & Foundry Co proposes to construct a new foundry addition for the production of sanitary pipe. The National Cast Iron Pipe Co. will soon commence the erection of an extension to its pipe foundry at Tarrant City, and the McWane Cast Iron Pipe Co has broken ground for its proposed new plant in the East Birmingham district.

The Tonopah Extension Mining Co., Tonopah, Nev., is arranging for capacity production at the local McNamara mill, recently secured under lease. Operations will be on a basis of about 100 tons per day.

The Consolidated Cortez Mining Co., Cortez, Nev., is completing the construction of a new mill and plans to place the unit in service at an early date. Initial production will be on the basis of 100 to 150 tons of handled ore per day.

The National Tin Co., Hill City, S. D., is arranging for increased production at its plant, and proposes to develop an output that will produce about 125 tons of metal at the smelter per month.

MISCELLANEOUS—The Widen-Lord Tanning Co., Danvers, Mass., is maintaining full production at its local tannery, specializing in the production of elk leathers.

H. B. Johnston & Co., Toronto, Ont., are running full at their local tannery for the production of calf leathers. A full working force is being employed.

The Owosso Sugar Co., Owosso, Mich., is operating at full capacity at its local mill. Plans are being considered for the reopening of the Lansing, Mich., plant of the company, which has been inactive since last June.

The Mt. Clemens Sugar Co., Mt. Clemens, Mich., is running full at its local mill, which has been in active service since Oct. It is expected to maintain the present schedule for a number of weeks.

E. I. du Pont de Nemours & Co., Wilmington, Del., are discontinuing operations at their plant in Wayne Township, near Paterson, N. J., heretofore devoted to the production of black powder. The machin-

ery will be removed to a works at Hillsdale Junction, near Scranton, Pa.

The Producers' & Refiners' Co., Fort Steele, Wyo., has completed the construction of the first unit of its new local refinery, and plans to place the plant in operation early in February. It will operate on a basis of 5,000 bbl. per day.

The Electro-Chemical Co. of Canada, Niagara Falls, Ont., is planning to operate a local plant for the production of nitric acid for general commercial use. A department will also be operated for the manufacture of calcium nitrate fertilizers. Existing plant facilities will be arranged for the new production with continuance of operations for present products.

The Calera Lime Works, Inc., Birmingham, Ala., is maintaining capacity production at its plant, and owing to heavy orders eliminated the annual shut-down during the holidays. A new kiln has been installed and other plant extensions will be made. A full working force is employed.

The Union Bag & Paper Co., Cheboygan, Mich., is increasing production at its plant, and machinery idle for some time past has been placed in service. Present operations are on a basis of about 70 tons of paper per day, and this will be increased to more than 100 tons daily at an early date.

The Michigan Sugar Co. has full-time production in force at its Caro, Mich., mill with employment of regular working quota. It is proposed to maintain capacity ouput for some time to come.

New Companies

THE CAVALIER CHEMICAL Co., Winston-Salem, N. C., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are E. M. Spivey and Wesley Taylor, both of Winston-Salem.

THE PENINSULA RUBBER Co, Boston, Mass., has been incorporated with a capital of $90,000, to manufacture rubber products. Andrew P. Keegan is president, and Lawrence F. Keegan, 505 East 6th St., South Boston, treasurer. The last noted represents the company.

THE PREFERRED CHEMICAL CORP., New York, N. Y., care of Isador Leifer, 110 West 40th St., New York, representative, has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are S. D. Silverman, A. Siegel and E. M. Neilson.

THE ATLAS PULVERIZING Co., 136 West Lake St., Chicago, Ill., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture paints, pigments, etc. The incorporators are Samuel E. Hirsch, Eugene I. Kalmuk and H. V. Gressang.

THE ESSEX ANALYTICAL LABORATORIES, INC., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are Paul C. Schotte, William A. Tries and Charles B. Clancy, 810 Broad St., Newark. The last noted represents the company.

THE COATES BRICK & TILE Co., Kansas City, Mo., has been incorporated with a capital of $15,000, to manufacture brick, tile and other burned clay products. The incorporators are W. W. Coates, A. O. Kickel and A. J. Moorhead, all of Kansas City.

JOSEPH A. MAGILO, INC., New York, N. Y., care of J. A. O'Rourke, 299 Broadway, representative, has been incorporated with a capital of $10,000, to manufacture chemical specialties. The incorporators are J. A. Magilo and S. S. Bemstein.

THE MOORE OIL & REFINING Co., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $500,000, to manufacture refined oil products.

THE CALIFORNIA PRODUCTS Co., Houston, Tex., has been incorporated with a capital of $25,000, to manufacture extracts, vinegar, etc. The incorporators are G. A. MacFarland, A. D. Baker and O. E. Gilleland, all of Houston.

THE SANFORD MFG Co., 846 West Congress St., Chicago, Ill., has been incorporated with a capital of $250,000, to manufacture inks, pastes, sealing wax and kindred specialties. The company is operating a plant at Congress and Peoria Sts. The incorporators are William K. Otis, Roy P. Kelley and William C. Boyden, Jr.

THE NATIONAL CHEMICAL PRODUCTS Co., Union Hill, N. J., care of Edward Hollander, 8 Bergenline Ave., Union Hill, representative, has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The incorporators are Richard D. Zucker and Joseph C. Bender.

THE SMITH-ALSOP SOUTH BEND PAINT Co., South Bend, Ind., has been incorporated with a capital of $25,000, to manufacture paints, varnishes, oils, etc. The incorporators are Edward A. White, Guy W. Frederick and Floyd E. Dix, all of South Bend.

THE MOAVA PRODUCTS CORP., Rochester, N. Y., Care of Reed, Shutt, Downs & Shutt, Wilder Bldg., Rochester, representatives, has been incorporated with a capital of $650,000, to manufacture chemicals and chemical byproducts. The incorporators are E. W. Hinman, F. W. Clements and F. W. Townsend.

THE SOUTHERN BRICK Co., Knoxville, Tenn., has been incorporated with a capital of $25,000, to manufacture brick, tile and other burned clay products. The incorporators are Reed P. Black, Leo I. Fanz, and Charles H. Smith, all of Knoxville.

THE GOLDEN WEST PETROLEUM CORP., Los Angeles, Calif., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $10,000,000, to manufacture refined petroleum products. The incorporators are Sherman S. Clark, James E. Kelby and King C. Gillette, all of Los Angeles.

THE GARDINER FOIL Co., 1356 West Lake St., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture tin foil and other composition foils. The incorporators are Robert A. and Harry J. Gardiner and F. W. Murray.

THE HALL-SPIERS BRICK Co., Berlin, Conn., has been incorporated with a capital of $75,000, to manufacture brick, sewer pipe, tile and other burned clay products. The incorporators are Wilson and Paul H. Spiers, Cambridge, Mass.; and Frederick M. Hall, 77 Wallace St., New Britain, Conn. The last noted represents the company.

THE VALE CHEMICAL Co., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws, with a capital of $100,000, to manufacture chemicals and chemical byproducts.

THE CITY CHEMICAL Co., Jersey City, N. J., has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The incorporators are Henry, Jerome and Max Wolpert, 67 Van Winkle Ave., Jersey City. The last noted represents the company.

THE KEYSTONE CARBON Co., Huntington, W. Va., has been incorporated with a capital of $2,000,000, to manufacture carbon and oil products. The incorporators are T. W. Scott, H. Blaidell and H. T. Lovett, all of Huntington.

THE ILLINOIS GLASS Co., 402 West Randolph St., Chicago, Ill., has been incorporated with a capital of $11,100,000, to manufacture bottles and other hollowware. The company is now operating plants at Alton, Ill., Bridgeton, N. J., and other points. The incorporators are John M. Levis, E. M. Ashcroft, Jr., and C. J. Lord.

THE CAPITOL BRICK Co., Newark, N. J., care of Gifford & Miller, 763 Broad St., Newark, representatives, has been incorporated with a capital of 20,000 shares of stock, no par value, to manufacture brick, tile and other burned clay products. The incorporators are Arthur H. Wolfe, Clarence S. Dame, and C. G. Towne.

THE HANSEN RUBBER PRODUCTS Co., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with a capital of $250,000, to manufacture rubber products.

THE BELL LEATHER CORP., Peabody, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. Rogers M. Crehore, 20 Chase St., Danvers, Mass., is president and treasurer, and represents the company.

THE FLORIDA HUMUS Co., Zellwood, Fla., has been incorporated with a capital of $200,000, to manufacture fertilizer products. John A. Hayes is president; Robert J. Rosenthal, vice-president; and Michael J. Perez, secretary, all of Zellwood. The same officials have also organized the ALPHA Co., with similar capital of $200,000, and location, to manufacture like products.

THE PHYMOS CHEMICAL LABORATORIES, INC., Pensacola, Fla., has been incorporated with a capital of $45,000, to manufacture chemicals and chemical byproducts. The incorporators are V. J. and John J. MacIntire, both of Pensacola.

THE GENERAL PLATING WORKS, INC., 2600 Prairie Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to operate a metal-plating plant. The principal incorporator is Lee J. Howard.

Capital Increases, Etc.

THE AMERICAN OIL & SUPPLY Co., 288 Wilson Ave., Newark, N. J., has filed notice of increase in capital from $100,000 to $500,000.

THE HENDERSON TIRE & RUBBER Co., Buffalo, N. Y., has filed notice of increase in capital from $550,000 to $650,000 for proposed expansion.

THE DIAMOND GLUE Co., Robinson St., Chicago, Ill., has filed notice of increase in capital from $500,000 to $2,000,000 for general expansion.

THE DAMON OIL Co., Tulsa, Okla., has filed notice of increase in capital from $50,000 to $1,000,000 for proposed expansion.

THE CAMDEN POTTERY Co., Camden, N. J., manufacturer of sanitary earthenware products, has arranged for an increase in capital from $200,000 to $500,000.

THE EASTERN TANNERS' GLUE Co., River St., Gowanda, N. Y., has arranged for an increase in capital from $1,500,000 to $2,500,000 for general expansion.

THE DUNLOP TIRE & RUBBER CORP. OF AMERICA, River Road, Buffalo, N. Y., has disposed of a bond issue of $15,866,700, a portion of the proceeds to be used for expansion.

THE OAKLAND CHEMICAL Co., 59 4th Ave., New York, N. Y., has filed notice of increase in capital from $10,000 to $750,000 for general expansion.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1923.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 8 and 9, 1923.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

H. C. PARMELEE, Editor

Volume 28 • New York, January 17, 1923 Number 3

Benjamin Franklin And National Thrift

THE date of this issue is the 217th anniversary of the birth of BENJAMIN FRANKLIN. There is probably no American living who will remain so eminent. He was a printer and publisher, which we of today count an abundant calling. He addressed himself for the short period of six years to science, and who can match the signal importance of his discovery? Having completed his work in respect to electricity, he regarded the matter as a closed book and hardly even referred to it again. He signed the Declaration of Independence, and those of us who can boast of any ancestor who was a "signer" are disposed to be rather cocky about it. He organized the U. S. Post Office. He was a philosopher and contributed richly to the thought of the eighteenth century. In his old age he was a great and successful ambassador; proving himself a master of statecraft. And he had a great and glorious time in living.

Throughout his days he preached and practiced the gospel of thrift. He kept the thought alive in his mind that material progress is dependent on savings. We know this just as well as FRANKLIN did, but we don't hold fast to the idea. We let it slip away unremembered. We know that every railroad, every telegraph and telephone line, every business undertaking, is established and organized and brought into being and into function by means of dollars that have not been spent on living. Whatever we earn and do not spend is in the bank, or in life insurance, or in investments. Few of us keep it in stockings. The capital of a nation is the reserve of that nation; the reserve that has not been spent on living. We may not make loans on investments ourselves, but if we do not, then our banks do. Whatever we set aside becomes busy money. The reason why we do not make the loans and investments is because we do not save enough. As soon as we have enough, then we buy bonds and stocks, or real estate, or let out our money on bond and mortgage. If we do not save, but spend whatever we earn on living, we do not participate in the wealth of the nation. We are out of it as contributors. We may make wealth by what we do, but the direct contributors are the owners of the shops where we spend our earnings. As between the improvident man who adds by his thought to human welfare and the publican with whom he spends his substance, the source of value is with the former, but the credit and the rewards go to the latter. FRANKLIN knew this and sensed it; hence his constant preaching to save pennies. We all know it too, but many of us do not sense it well enough to remember it when pay day comes around. So the week following FRANKLIN'S birthday has been selected and established by a large number of organizations as Thrift Week. Thrift is to be preached and sounded and rung out and declared by all the arts of advertising and suggestion and applied psychology.

It's curious, but when we consider the contributions of America to the philosophy of life, the first American philosopher who was not at once a theologian and a dogmatist urged thrift upon everybody. And yet of all the civilized nations of the earth our thrift index is certainly the lowest in proportion to our earnings. It is absurd to declare that, so long as money is in circulation, it adds to wealth. It doesn't. Let's take a concrete example. Suppose you have a farm on stony ground. You employ ten men at $3 a day to pick up the stones from one field and throw them into another. Then you employ the same ten men to pick up stones from the second field and throw them back again into the first. They have been employed, and have had their wages, but nothing has been accomplished by you. That is an example of luxury. But suppose you employ the same men to throw the stones from the first field upon a pile and then to plough and sow the field, the while you sell the stones for road-making. That is an example of thrift, and you have a good farm and some extra capital to operate it, while the community has a good road.

It takes head-work to save. The lower orders of people, the inferior persons, can't sense this. They can't compute consequences. But intelligent people look ahead and adjust expenditures to income. They set aside what they do not use. They are wise, like the thoughtful men who made our country for us.

M. C. Whitaker, Perkin Medalist

ADDED to the roster of those distinguished industrial chemists who have been awarded the Perkin medal is the name of MILTON C. WHITAKER. In his selection the representatives of the Society of Chemical Industry and the affiliated chemical and electrochemical societies have indeed made a happy choice, for measured in the wholesome esteem of his fellow chemists WHITAKER is without a peer. And in his industry his position is equally unique. Many of us have acquired the habit of referring to him with some little pride as the sort of executive that is sorely needed by many of our chemical industries. Our respect for him is not solely prompted by the fact that he is a technical man in charge of a great technical organization, but al- because, as a man of vision, he has guided that organ zation with a full sense of the fundamental value of th science on which it rests. At a time when many shor sighted industrial leaders were abandoning researc and scrapping their investigational department, scie tific inquiry under Dr. WHITAKER'S direction was bein prosecuted with increasing zeal. The result was th great and fundamental accomplishment came from h laboratory and research plant. Development work w

continued even during the worst of the business depression. Several products once regarded only as laboratory curiosities were brought out on a large commercial scale. The marketing of absolute alcohol in tank car quantities is but one of the signal accomplishments destined to have almost revolutionary effect on many industrial processes and materials.

To learn of Dr. WHITAKER'S early life and environment is to account for much that he is today. Even as a student he was able to go out in charge of Western lumber camps. This indicated at an early age his leadership of men and his ability to get things accomplished with the least waste of time and money. His native gift and later development of mechanical skill has stood him in good stead. One of his old professors says of him, "He could always do anything with his hands." His unusual power to grasp details in plant construction and to sense and remedy operating defects give credence to the statement. Insights such as these characterize ARTHUR D. LITTLE'S excellent appreciation of the life and human qualities of the medalist.

But it is primarily as an organizer that Dr. WHITAKER has been honored. He has built up organizations that stand as monuments to his record of constructive achievements. In his address of acceptance, we believe our readers will find an unusual exposition of the basic principles that underlie all industrial organizations. He sounds the keynote for success, not alone for chemical production, but in all lines in which science is applied to industry.

Get Out Of the Red

IN what follows we should like to talk to the men responsible for technical control, to the men in charge of the testing department, to the men who are interested in putting quality into the product.

It is seldom realized that the total volume of production of a manufacturing organization is attained through two main groups of influences. First, there are what might be called positive factors—a great number of circumstances such as labor-saving equipment, proper routing, low turnover of workmen, all together swelling the production. It is upon these favorable factors which the "efficiency expert" and production manager spend the most time. Every success is properly bulletined, and appears in the most favorable light in the daily reports going over the manager's desk, and in turn are passed on to the board of directors. None of the latter are so obtuse as to doubt that men who can increase the production of a certain machine by 10 per cent are valuable employees.

But not all the working conditions are favorable. There are a number—often a surprisingly large number—which may be grouped as negative factors, influences which tend to decrease production. In a plant manufacturing articles of metal many of these factors have to do with the quality of metal entering the plant, and of the tools used in its fabrication. And the activities of the metallurgist and the testing department are to a great extent confined to the removal of these drag anchors. Their work is not spectacular, it does not advertise itself, and unfortunately those men actually doing the work do not see to it that the manager gets news of their successes. Nobody makes much of a fuss about the rejection of a certain shipment of metal, practically certain to produce 10 per cent faulty pieces—nobody perhaps except the purchasing agent who thought he was getting a bargain in raw material. But it requires no argument to prove that the man who can prevent a large percentage of rejections (or dissatisfaction by customers) is as important as he who can get ten completed units where nine only came before.

In short, total production is the difference between positive factors and negative. The metallurgist often is intent on cutting away the latter, and rightly, but unfortunately his successes never are segregated in the reports, and he seldom can point to a certain positive thing as his achievement. What is more natural, then, than that he should be regarded merely as a salary expense to be lopped off at the first demand for economy?

Metallurgists, to come into their own, must therefore get off the debit side and into the credit side of the ledger. Cultivate the auditor, and have him start an account for the testing department, as he has already done for the warehouse. These people usually do business like a department store—they buy and stock all manner of things used about the plant, and sell them upon demand, charging a sufficient margin to cover the cost of handling, purchasing and bookkeeping. At the end of the year, they show a certain small profit on the books. Is this service fundamentally different from that rendered by the testing department? If the purchasing agent were to have a shipment inspected and analyzed by an independent laboratory he certainly would expect to pay for the report, and the expense would be loaded on the selling price when the material left the warehouse. Or, if the grinding department was having troubles with "alligator cracks" and secured the advice of a consultant, they would not balk at the fee.

Just because a plant has a testing department, metallurgist and chemist is no reason why that department or those men should be called upon to do all these jobs for everybody gratis. The surest way to get on the right side of the ledger is to have a departmental account started. Then charge a fair fee for the services rendered, and insist upon a credit whenever large savings result from an independent investigation. You'll be surprised how quickly you get out of the "red ink."

Lime Manufacture A Chemical Industry

"OUR aim has been to place the lime industry on the same footing as any other chemical industry. In the past it has, in this country [England], been treated more like the manufacture of bricks for example; and even in America it is only in recent years it has risen to its proper place as the industry concerned in the manufacture of one of the most important chemical reagents."

The compliment which is so gracefully expressed by our British friend quoted above is well deserved by some of the American producers; but there are others who still lag far behind in their progress toward a better understanding of what chemical lime really is, what standards of composition and performance can be expected of it, and how most economically to produce the optimum quality. The statement really indicates only an important trend in this important industry. It is a trend that might be speeded up by greater chemical activity in lime manufacture without any detriment either to manufacturers or users.

The making of high-grade chemical lime at the lowest cost demands no little chemical engineering skill. He who neglects to recognize this fact will shortly find himself outdistanced by more progressive competitors.

What's Behind The Stock Dividend?

THE EPIDEMIC of stock dividends which broke out so virulently during the closing months of the old year continues to excite public discussion. Opinions continue to differ widely as to their purpose and effect. In view of the leading part played by the Standard Oil group in the distribution of such dividends, particular interest attaches to the vigorous defense of the policy advanced by A. C. BEDFORD in his recent address before the American Petroleum Institute at St. Louis.

Mr. BEDFORD flatly denies that stock dividends result in any tax evasion. Further he makes a strong plea for the essential soundness of the process of building up a surplus from current earnings, plowing it back into the business and capitalizing it through the issuance of new shares to old stockholders. The issuance of the stock dividend, he insists, means merely "changing a dollar into four quarters." It creates no new wealth.

Economists and accountants generally will agree that the simple act of declaring a stock dividend creates no new wealth. They will also agree that the increase of the capital fund is essential to the progress of business and the country generally. Finally, they will admit that the stock dividend does not offer a method of tax evasion in any legal sense. However, having conceded all of these points, an honest, inquiring mind may still hunger for a deeper analysis than Mr. BEDFORD has made. Is there nothing more than this to the stock dividend epidemic? Is there no rational explanation for the conviction so generally prevalent that the stock dividend is significant of some condition which needs correction?

Mr. BEDFORD apparently accepts the orthodox definitions of wealth and income, for he argues that the stock dividend is not income because it creates no "new wealth." One has income when his wealth—his economic strength, in the sense of command over goods and services—has increased. This is the general conception of income which underlies our federal income tax law. With this definition in mind, let us raise a few queries which may serve to clarify the issues.

Suppose you were to invest twenty-five cents in the Standard Oil Company of New Jersey. Suppose the company prospers and builds up a large surplus, your share of which amounts to the value of seventy-five cents, so that your interest in the company is now worth a dollar. Suppose the company declares a stock dividend "changing the dollar into four quarters." Has anything of significance happened? Has your economic strength increased? Have you received any income?

Clearly the stock dividend simply recognizes an existing situation. It recognizes that the quarter has expanded into a dollar and makes the convenient "change." But the significant thing is that you are ahead to the extent of seventy-five cents in value—not merely because of the stock dividend—but as the result of the whole process. At the beginning you had a quarter invested in productive enterprise. Now you have an investment worth, by assumption, a dollar.

The real nub of the matter from the tax point of view is this: The process described in the above example is about the only way you can make seventy-five cents and reinvest it in productive enterprise without subjecting the three new quarters to the heavy surtaxes of the federal income tax. The corporation pays the normal tax (slightly higher, it is true, than the individual normal rate) when it adds the new quarters to surplus, but you are asked to account for them only *if* and *when* the corporation distributes them to you as a cash dividend or *if* and *when* you sell your stock at the enhanced value due to the surplus which has been built up. Thus, this "if and when" is of considerable importance.

If you had invested your original quarter in an equally prosperous individual enterprise or partnership you would have been asked not only to pay the normal tax as the new quarters were earned and reinvested, but would also have been compelled to pay the surtaxes on them *when earned* rather than "if and when" distributed or "if and when" the stock was sold at an advance.

Clearly the corporate form of business organization has an advantage under the tax law because of this situation and the stock dividends are advertising this advantage in a most striking manner. It is this advantage which is really the shining mark at which the "agitators" are aiming. Is it not an advantage which must in some manner be equalized if the "sturdy qualities" of individual initiative and resourcefulness, which Mr. BEDFORD so properly praises, are to be given full play?

How to accomplish this is, indeed, perhaps the most puzzling tax problem which the federal government is facing. It cannot be solved by refusing to recognize its existence or by approaching it from the point of view of one industry, one form of business organization, or one economic class. The differential in favor of the corporation may conceivably be removed by increasing the burden on the corporations or by decreasing the burden on the other forms of business enterprise. The "agitators" suggest a new tax on the undistributed surplus of corporations as closely equivalent as possible to the present surtax burden on reinvested earnings of other forms of business enterprise—a suggestion which Mr. BEDFORD labels "a proposal of sabotage by legislation." The fear of such a tax is probably a contributing cause, although not the sole or perhaps not the most important cause of the stock dividend epidemic. The alternative plan for eliminating the corporations' differential would be to reduce the present burden upon reinvested profits of partnerships and individuals. But he who proposes this must be prepared to convince the public that a dollar of wages should be more heavily taxed than the dollar of reinvested profit. This is the dilemma!

Co-operating With The Customs Authorities

MORE than usual significance attaches to the important series of conferences now under way for the purpose of considering the proposed rules and regulations which will govern the Treasury Department in administering the new tariff law. For the first time in history manufacturer as well as importer is being given a chance to participate in the discussion. He is expected to contribute valuable basic information on prices and commodities, particularly as regards coal-tar products. The tariff act of 1922 contains many snarls of construction and definition which are yet to be untangled and the net result of these conferences will often determine whether or not certain of the protective provisions will actually become effective. Later, it is our intention to give more detailed consideration to some of these administrative difficulties, but in the meantime we believe that the customs authorities should receive the fullest co-operation from the chemical industry.

Milton C. Whitaker, Perkin Medalist, 1923

Sixteenth Award for Meritorious Accomplishments in Applied Chemistry Goes to Industrial Leader Characterized as "Investigator, Organizer and Doer"—Addresses of Appreciation by Associates—Presentation by Charles F. Chandler

IT IS particularly significant that this year the Perkin medal should have been awarded to an outstanding industrial leader who has actively sponsored fundamental research and through it has built up a great and lasting chemical industry. These were the "meritorious accomplishments in applied chemistry" that prompted the joint committee of the chemical societies to award this coveted medal to Milton C. Whitaker, president of the U. S. Industrial Chemical Co. and vice-president and director of the U. S. Industrial Alcohol Co. The presentation took place under auspicious circumstances at the meeting of the American Section of the Society of Chemical Industry, held in Rumford Hall, New York City, Jan. 12, 1923.

In his introductory remarks, Prof. Ralph H. McKee, chairman of the section, referred briefly to the founding of the medal in 1906 and to the list of illustrious chemists, beginning with Sir William H. Perkin himself, who have since received the award. At this point a little leaven was added to the otherwise heavy program by the reading of a number of congratulatory telegrams, not the least significant of which came from the Anti-Saloon League of America and the Kelly-Pool Gang of the Chemists' Club.

The first of the speakers was Arthur A. Backhaus, introduced by Chairman McKee as "one of that large group of young men who have worked under and with Dr. Whitaker and have helped him to bring to successful accomplishment several significant commercial enterprises." Mr. Backhaus, with an apology that "a close-up on so large a subject is likely to be very much out of focus" proceeded to share with the audience his "Impressions of the Medalist." His views in part were as follows:

Some Impressionistic Views of Whitaker

By Arthur A. Backhaus

During the summer of 1914 Dr. Whitaker, then head of the chemical engineering department at Columbia University, was seeking an assistant. Professor Chambers, with whom I had done my undergraduate work recommended me for the job, which in turn was offered me and I accepted it. The entire negotiation consisted of but two letters, one in which the position was offered, the other in which it was accepted, although neither of us knew the other. I arrived in New York on the morning of September 16, and in the afternoon I reported to Havemeyer Hall, Columbia University, wondering what my new boss was going to look like. Dr. Whitaker was in his office, seated at his desk, completely filling a roomy chair. He had his coat off, sleeves rolled up, hair ruffled, hard at work as one usually finds him. I was impressed, not only by the size of the man but also by his speed, "his velocity coefficient," for before I knew it I had been hustled into the laboratory and put to work. From that day until now I have been honored in calling Dr. Whitaker my boss.

Some Personal Characteristics

Dr. Whitaker has an unusually keen insight into chemical processes and chemical plants. He can size up a plant operation, see the weak spots and suggest remedies or improvements. He invariably turns the spot light on jokers in proposed new processes. His mind not only grasps broad features and general principles, but also takes in minute details.

Dr. Whitaker has said on several occasions, that the successful plant or works superintendent must have the faculty of instinctively "happening on the spot" at the psychological moment.

I have often been impressed with the fact that Dr. Whitaker can make a little chemistry go farther than any man I know. This applies not only to chemistry but to other information. His ability to apply knowledge or practice from an unrelated field to a problem at hand comes up again and again.

It is probably not necessary to dwell upon the ability of Dr. Whitaker to express himself in clear and forcible English. His clearness in expression is due to his extensive vocabulary and his apt choice of similes and metaphors. Many here have probably heard him speak of research chemists as "prima-donnas who must be handled with kid gloves." Unfortunately his most picturesque expressions would not appear well in print.

Dr. Whitaker differs from many other executives in that he thinks his problems out clearly and completely. He not only fixes a definite goal, but also works out, in his own mind, at least one good way of reaching it. In all his dealings with his men he plays the game with all his cards on the table.

Conferring the Medal

Following the delivery by Arthur D. Little of his inspiring appreciation of the medalist, Dr. Charles F. Chandler, senior past president of the Society of Chemical Industry in America, was called upon to make the actual presentation of the medal. The venerable dean of American chemistry read portions of his prepared address which reviewed the life of Dr. Whitaker and listed references to all of his patents and published articles. "It gives me the greatest pleasure," he said, "as the representative of the Society of Chemical Industry and the affiliated chemical and electrochemical societies of America, to place in your hands this beautiful Perkin medal, as a token of the appreciation and affection of your fellow chemists."

In expressing his deep appreciation of the honor thus conferred upon him, Dr. Whitaker said:

> It has been my good fortune to be an organization man rather than an individual worker. Achievements which have resulted in the award of the Perkin medal to me are necessarily therefore achievements of the men with whom I have worked. It would be a pleasure to catalog the names and individual accomplishments of these men, but the list would be so long and involved that it is probably better at this time to generalize. Accordingly the medal is accepted by me, in a representative capacity, as a distinguished honor conferred by the American chemical profession on these men with whom I have been associated in the 30 years devoted to study and practice in the field of applied chemistry.

Dr. Whitaker's address of acceptance, a remarkable exposition of the principles of organization, will be found on pp. 104 to 109.

Chem. & Met., Jan. 17, 1923.

Whitaker and His Work

BY ARTHUR D. LITTLE

MEN are sometimes distinguished for what they do and sometimes for what they are. More rarely are we permitted to honor them for both. Milton C. Whitaker is a chemist who has earned distinction by his works, but he is first, last and all the time a man.

The realm of Chemistry is not a single and isolated state, nor are its workers unionized. It is, instead, a Commonwealth of Federated Nations, each rich in resources of its own which require special aptitudes for their development.

So it happens that Chemistry can only realize the potentialities of her estate through the co-ordinated efforts of workers of many types and diversified endowment. Some must be patient and persistent garnerers of facts and gleaners of detail; others, highly skilled manipulators to divide that which we have called the indivisible. Some must be students and thinkers, whose thinking leads to generalizations. There must be teachers and expounders, to spread the truth, and doubters and disputants, lest error pass for truth. Finally, that mankind may derive material benefits from these accumulations of knowledge, there must come the organizer and doer, whose bottles are tank steamers, whose test tubes are digesters, and his beakers 50,000-gallon tanks. As student, teacher, editor, Milton C. Whitaker has won high place in our esteem, but tonight it is primarily for his position and achievement as the organizer and the doer that we are met to honor him.

MILTON C. WHITAKER

Those of us whose professional activities center in the study, the class room or the laboratory are commonly inclined to award a disproportionate meed of merit to that one whose discovery of fact, material or reaction supplies the basis for a great industrial development. They seldom recognize or appreciate the obstacles and difficulties along the steep and rocky road which leads from the laboratory to the plant. They do not see the caulkers on the first Burton still closing the leaking seams between hot boiler plates in an atmosphere of gasoline. They do not know how it feels to work sixty-four hours at a stretch to push along repairs or how Saturday looks on Friday with no money in the bank to meet the pay roll. It is a wise invention that knows its own father. Countless examples can be adduced to show that the organizer, the adapter, the engineer plays a part in the development of industry that is often vastly more constructive than that of the discoverer. We commonly and properly attribute the telephone to Bell, but the instrument as we know and use it is the child of many minds and the godchild of the organizer. Barconnot, in 1918, effected in a laboratory operation the conversion of cellulose to sugars and through them to alcohol. It required thereafter nearly a century of effort to transform that relatively simple laboratory procedure into a commercially operative process. The vast and intricate coal-tar industries, which have so greatly stimulated chemical science, owe their many-sided development as certainly to the organizer and administrator as to the laboratory worker, even though that worker be Perkin himself. It is, therefore, peculiarly fitting that the medal, which commemorates Perkin's great contribution to our science and to industry, should this year be bestowed on one who has shown superlative ability in the application of chemistry to industry on the grand scale; who has the faculty of sensing fundamental principles and necessities in their broad commercial and economic relationships and of building on them great producing agencies.

Milton C. Whitaker was born in Frazeysburg, Ohio, December 16, 1870. Doubtless there were boys in Frazeysburg who tried to lick him, but history records none who did. Later, his family moved to Colorado, and during the four years beginning with 1890 young Whitaker worked in the various lumber mills of Stubbs and Jakway, cherishing always the ambition for a college education and a degree in chemistry. The youth showed the quality of the man, and concerning his work the testimony of his employer may be thus summarized. Ability as a mechanic was evident from the first and with it a natural and unusual power to grasp details and detect and remedy defects in plant and operation. He soon became master-mechanic and when a little later, owing to the exhaustion of the local supply of timber, it became necessary to dismantle the mill, transport the equipment and re-erect and house it on a new site, the task was assigned to Whitaker. So well did the youth repay the confidence that the new mill proved the most successful that the company had operated. In 1896 the company decided to build another mill and for this Whitaker, though then at college, prepared the working plans and during his summer vacation supervised construction. It was a good mill, of which its owners said years afterward, "It has not lost a single day because of faulty construction."

So Whitaker earned and saved and studied until in 1897 he was graduated from the Universty of Colorado with the coveted B.S. degree. Degrees have this in common with olives in a bottle and the kisses of a girl:

The first one is hard to get, but the others come more easily. An M.S. from Colorado followed in 1900 and an LL.D. in 1913, and to these the University of Pittsburgh added Doctor of Chemical Engineering in 1915.

Following his graduation Whitaker became instructor in chemistry at Colorado and in 1898 tutor in chemistry at Columbia. Here he came under the benign and stimulating influence of that honored and beloved dean of applied chemistry in America, Dr. Charles F. Chandler, whom he was privileged to serve as private assistant for nearly four years. That in itself was a liberal education.

His Impress of the Mantle Industry

Whitaker's intimate contact with chemical industry and his constructive influence thereon began in 1902, when he went to the Welsbach Co. as chemist, on the recommendation of Dr. Chandler, who had for years been its consultant. From Whitaker's associates in this new connection one learns that his impress on the organization was almost immediate and ultimately profound. He was at first engaged upon work of a purely chemical character in the laboratory under the direction of Dr. H. S. Miner, but through the laboratory he was gradually brought into general touch with the operations of the plant. Whitaker had been with the company only five or six months when Dr. Miner came down with typhoid fever, and the responsibility for production fell upon the shoulders of his assistant. As we should now expect, Whitaker handled affairs in the plant in a masterly way, going at once to fundamentals, and as troubles arose finding the means and methods for the prevention of their recurrence. Collodion was the bugbear of the industry. Its viscosity with the same solvent and concentration varied over wide and confusing range. As with most colloids at that time, little was known concerning methods of controlling this disturbing factor. Whitaker promptly secured a man experienced in the manufacture, installed a small plant, and worked out the problem of control with large resultant savings and the elimination of many difficulties elsewhere in the factory.

In 1903 he went to Shelby, North Carolina, to inspect the company's monazite mines and there became terrifically ill with a digestive trouble, from which he nearly died. It is reported, though difficult of credence, that "he returned a shadow." Happily, the substance is now restored to us.

With renewed health came his appointment as general manager of the company, and Whitaker initiated a general campaign for the improvement of the hidebound methods of the mantle industry. He worked out a new flow-sheet and rearranged the factory. He enunciated the principle that "a man is as good as his boss," and with this sense of responsibility for their performance he picked leaders with a wise discretion and developed them into departmental heads. His ambition was to evolve a self-contained plant and an organization he could leave. He fixed responsibilities and demanded results, organized weekly conferences, established systems of reports that stimulated healthy rivalries, wrote historical and educational bulletins for the sales department, developed a research laboratory and a system of control throughout the plant, built a club house for girl employees, installed a hospital, invented testing machines. He put in a print shop to obviate delays, a lamp shop to broaden sales, a development shop for the incubation of new mechanical ideas. By standardizing the process of collodion dipping he saved twenty per cent of the collodion used. He substituted the electric drive for rope transmission, developed machines to replace hand labor, invented the present system of packing the fragile mantles, improved the equipment and methods of the bleaching room. In short, he was responsible for betterments in practically every stage of the manufacture in the company's plants at Gloucester, New Jersey, Chicago, and Columbus, Ohio, and he left his impress on the industry from the time the order was received until the goods went out on the platform. It is an achievement to handle material efficiently. Whitaker did far more. He developed *esprit de corps* in men and women, created an organization from human beings, and secured and held their warm affection. Small wonder is it that during his connection with the Welsbach Co. costs of production went down steadily and its business more than doubled.

The Return to Columbia

It was with such a background of achievement and experience that Whitaker returned to Columbia in 1910 as professor of chemical engineering. Of his work and influence while there we cannot do better than record the impressions of a student whom he inspired, of a close associate who worked with him in understanding sympathy, and of Dr. Nicholas Murray Butler, his administrative chief.

The student says:

"It was heretical to cut one of Dr. Whitaker's lectures, and there were never heretics. A class convening for a quiz on multiple-effect evaporation would find, after the bell had rung, that the subject of discussion was the longshoremen's strike just declared that day in New York City. The quiz on evaporation would be given at the following session. In the meantime, wages, living conditions, labor policies and legislation were moved down stage for closer inspection. A chance remark by someone in the class would cause the interruption of the order for the day while some principle of professional ethics, industrial justice or downright decency was explained in a manner that left an indelible impression on the minds of young men. The verbiage of technical texts was never heard in Dr. Whitaker's classes. Even in the routine of teaching fundamentals, things sounded different, more tangible, more homely. And when those fundamentals were brought forth for application to practical problems the pedagogic atmosphere was dispersed completely. Dr. Whitaker's students have perhaps forgotten where they first learned how to select the right type of filter press, but they will always remember who taught them to think like engineers and to behave like men."

The estimate of the associate is this:

"Nothing but a long talk could possibly cover the subject of Whitaker and his work. I suppose his outstanding characteristic might be called moral and professional courage, with a very high order of sales ability. He loved a problem, he loved to dig out its solution even more, but most of all he loved to put his solution across, to sell it against opposition. At Columbia he made Chemical Engineering. Without him it would never by any feature of identity have been distinguishable from Industrial Chemistry. This is history that went beyond Columbia."

Dr. Butler writes:

"I rejoice at the good news that Dr. Whitaker is to receive the Perkin medal. He certainly has earned it. He showed while with us marked initiative, administrative capacity and single-minded devotion to science. He realized to the full the close interrelations between what is sometimes called pure science and what is sometimes called applied science and he labored effectively to promote and to develop these relations. So vigorous was his work and so large his influence that a Department of Chemical Engineering was in fact, even earlier

than in form, set off from the Department of Chemistry and put under his direction. We look upon him as one of our own and follow his career with pride and satisfaction."

Combining Chemistry and Finance

Dr. Whitaker had always maintained that the effective teaching of chemical engineering required of the teacher close and continuing contacts with industry. In developing such contacts for himself, he soon established relations with those who stand within the circle of opportunity. His executive ability, soundness of judgment and technical attainments were quickly recognized. He gained the confidence of capital and effected that difficult synthesis which involves the combination of chemistry and finance. As a result, he was called in 1916 to become manager and in 1917 president of the Curtis Bay Chemical Co. and, following reorganizations, president of the U. S. Industrial Chemical Co. and vice-president and director of the U. S. Industrial Alcohol Co. In this latter capacity his position is, in one respect, undoubtedly anomalous. Most manufacturers strive to pass on to their customers the best they can produce. Whitaker turns out a product of surpassing purity, for which the demand is well-nigh universal, and he then deliberately, if not indeed maliciously, adds to it objectionable and insalubrious compounds which remove it from our sphere of non-professional interest.

The technical operations for which Whitaker is ultimately responsible in these two great companies are conducted on a scale of amazing magnitude. They afford convincing evidence of the fundamental importance of alcohol as an industrial raw material and justify the demand of our profession for less burdensome and more intelligent regulation of its industrial use.

The basic activity of these plants is, of course, the manufacture of alcohol from molasses, which in the sugar-producing countries was formerly thrown away in vast amounts. Obviously, however, when alcohol is made on the grand scale fermentation byproducts, though of small percentage value, assume a large significance. Here aldehydes, as well as alcohol, are utilized in vinegar making, fusel oil is split into its component alcohols, the carbonic acid, carefully purified, is compressed in cylinders, sulphate of ammonia and potash are recovered from the distillery slop by evaporation in multiple effect and furnacing.

The alcohol itself is marketed in many forms, each involving special operations. It may go out as tax-paid alcohol, 95 per cent or absolute, or as spirit denatured to meet the requirements of special industries or uses. Much is converted to the familiar solid alcohol and such amounts to tincture of iodine as to require a separate plant for the purification of the element by steam-distillation. Many thousands of gallons of anhydrous alcohol are daily mixed with gasoline to produce the motor fuel Alcogas. To those who, like ourselves, have regarded absolute alcohol as a laboratory luxury and who are familiar with the refinements required for its preparation, its production on this scale and at a cost permitting such use stands forth as a conspicuous technical achievement.

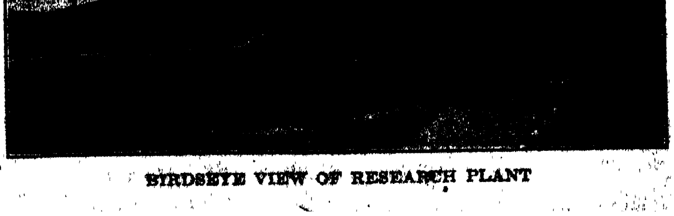
The range of Whitaker's professional work is further demonstrated by the varied subject matter of the twenty-two patents granted him as sole or joint inventor. Of these fourteen are in the former class. Among the inventions covered are containers for fragile gas mantles and those for gases and volatile liquids; processes of gas manufacture, distillation, pulping resinous woods, recovering catalysts, and making ethylene; apparatus of varied types and motor fuels. With it all he has found time to publish important papers to the number of twenty-five, dealing with such diversity of topics as the rare earths and their place in industry, water gas and oil gas, the war supply of nitrogen, the cracking of hydrocarbons, the carbonization of coal, and many others.

Professional Appointments and Offices

As members of the American Chemical Society, we gratefully acknowledge our own signal indebtedness to Whitaker for his upbuilding of the *Journal of Industrial and Engineering Chemistry* and for the stimulus of his editorials during the six years ending with 1916. If you would know Whitaker himself and his professional and business attitude, go back to his famous editorial of September, 1912, on "Fussy Administration." If you are an executive, or if you hope to be one, it will give you something to think about.

To the profession generally Whitaker has given generously of his time and effort. In 1911 he served as chairman of the New York Section of the Society of Chemical Industry and in 1914 as president of the American Institute of Chemical Engineers. He was for several years a member of the latter's committee on chemical engineering education and in December, 1910, presented clean-cut, constructive suggestions in a paper on "The Training of Chemical Engineers." From 1915 to 1917 he was president of the Chemists' Club, and that honorable office is no sinecure. While carrying his great responsibilities for the production of war materials at the plant of the U. S. Industrial Chemical Co. at Curtis Bay, he served for two years as advisor to the War Industries Board.

Such, in brief outline and under dim illumination, is the career of the man whom we are proud to honor tonight. We award the Perkin Medal to him because he has shown himself to be a great constructive force in the field of applied chemistry, but it is his intensely human quality for which, after all, we value him most dearly. His corpuscular count is high. He knows men and handles them with consummate skill. He can call a spade a spade and if necessary, he can call it something a whole lot worse.



BIRDSEYE VIEW OF RESEARCH PLANT

ORGANIZATION
The Keynote of Successful Chemical Production

by
Milton C. Whitaker

Address of Acceptance on Being Awarded the Perkin Medal by the American Section of the Society of Chemical Industry and Affiliated Chemical and Electrochemical Societies

ORGANIZATION for this or that purpose is a venerated topic for speech makers—especially efficiency experts and others with more or less amateur standing. Organization for chemical development and production has been spared much of this limelight, probably because of the new elements introduced and the greater difficulty in understanding the problem or even the language of chemical industry.

Nevertheless the fact must be recognized that no program of chemical production can be carried through without an adequate organization, any more than mechanical production can be accomplished without operators, or railroads run without men. While research chemists and physicists are laying the foundation for products, processes and plants, it is incumbent upon somebody to develop, study and perfect, concurrently, a suitable organization to carry their research results through the various stages of development and finally to profitable production. Furthermore, organized effort is obviously more rapid, efficient and thorough than single handed work, and this applies to every step from research to sales.

Accordingly, it seems appropriate, in spite of the overworked character of the subject of organization, to outline some of the methods which my associates and I apply to chemical development in order to arrive at the results which the committee of the Society of Chemical Industry has accepted as collectively justifying the great honor of the Perkin medal.

Eight Elements of Organization

Arthur Little once said "There is great danger in an organization chart—someone might mistake it for *an organization*." After this apt, if somewhat blunt, awakening, we would not venture even to submit an organization chart. For the purposes of developing and coordinating the work of organization, the problems requiring individual treatment and timing may be arranged under the following general heads:

1. Objective.
1. Direction and Policy.
3. Research and Engineering.
4. Construction.
5. Operation.
6. Office and Accounting.
7. Sales and Promotion.
8. General Seasoning.

Time will not permit a detailed analysis of the methods of development for each of these organization headings, but the system which we have followed may be illustrated by selected examples.

The objective of an organization requires the most careful analysis. This applies to all organizations, whether old or new. What is it supposed to do and for where is it headed? Obviously the scope and extent of an organization should be adjusted to the facts developed by such an analysis. Overorganization seems to be the most general fault. We saw many cases during the war where there was so much organization that there was no one left to do the work. Frequently we still find organizations "all dressed up and no place to go."

The direction and policy of an organization for chemical production is obviously, on account of its basic position, the most important element of the whole program. An organization without proper and carefully defined policy is like a ship without a rudder. It may gyrate around without going anywhere in particular,

or it may, in close quarters, do a great deal of damage, both to itself and to its neighbors. Furthermore, a policy should be carefully worked out in the beginning and must "stay put." Missteps in the formulation or execution of policy may be of little consequence at the time, but may at some future date loom up like a rock in the channel. In any project of development, therefore, direction and policy deserve and must receive, far in advance, the most profound and intelligent consideration.

Organizing Research

Research and engineering are the logical preliminaries to the development of any new program of chemical production, and we believe are equally necessary to improvement in the efficiency of established operations. Volumes have been written on the subject of organization for research. We claim no originality for the systems which we have adopted, but take this occasion to record some typical schemes followed in our work, in the hope that they may serve as guides to others in what to do or what not to do according to their desires or tastes.

The overhead set-up for research must be analyzed as a preliminary to any plan to develop a research organization. The objective, interest and resources available to the directors and executives are of primary importance in any research program. Their ability to understand the scope of our activities, their confidence in our abilities, their determination to see the thing through, and their capacity to stand disappointments, are qualities which must be measured and will form the foundation on which the program may be built. In short, ambitious researchers must exercise care in the selection of their bosses.

Many research projects are doomed to failure before they start, because of the lack of interest or understanding on the part of the overhead. If research is to be a part of an organization at all, it is entitled to the full benefits of co-operative support of every man in that organization from overhead to office boy. Research men are liable to be sensitive and sometimes temperamental. They respond to encouragement and wholehearted support, while on the other hand, a single knocker may wreck the works.

Sympathetic Direction and Support

The greater portion of our organized research effort has been with the Welsbach Co., Columbia University, the U. S. Industrial Alcohol Co. and the U. S. Industrial Chemical Co. The confidence and undivided support which we have received from the directors and officers of these organizations, and the mistakes they have stood for and paid for, form the basis on which we have been able to build recent organizations.

We always see to it that officers and directors understand what we are trying to do and how we are trying to do it. We discuss our projects and policies and program with them. We do not even deny them the privilege of sharing our disappointments and understanding our failures. We have received in return encouragement, confidence, support.

A president of a corporation or a chairman of a board who reads and understands the research reports, knows and follows the progress of the work of every chemist and engineer in the organization, who champions the fellow who is down and encourages the fellow who is up, and who interprets these results and conditions to his directors, may be a rarity in some programs for the development of chemical production, but in our cases he has been the inspiration. We attribute these conditions to the care we have exercised in the selection and training of our bosses. They doubtless will ascribe it to other reasons.

Our research organizations consist of personnel, equipment, problems. Diversifications of all three of these elements, within the scope of the project, is both necessary and desirable.

Picking Men for Team Work

We have no formula for the selection of the men. We do not believe any one can pick a winner every time from a group of available chemists. Our best guess, based on training, experience and temperament as disclosed by the candidate, is given a trial in the organization and the candidate is given reasonable time to adjust or eliminate himself by a process of natural selection. Many chemists who think they are research men are not qualified either by training, ability or temperament to handle research problems. Yet these same men may be or may develop into excellent plant men. It likewise follows that many chemists who think they are qualified by nature to handle plant problems are essentially research men. Some men are not fitted for either research, plant or sales and would probably do better in insurance or music. A man who is essentially a plant man is liable to be a nuisance in a research laboratory, and on the other hand, a man with research inclinations is a hazard to any production process.

Diversification of training and experience among the members of a research organization is of the utmost value when the organization works as a group. While each investigator may have his particular problem, team work is a necessary element in order to achieve the greatest results.

The man who is inclined or prefers to play a lone hand, who is selfish or secretive, is out of place in any organization. Individual effort is limited to the capacity of a single person, whereas the advantages of an organization should be capitalized by producing results which represent the combined effort and experience and knowledge of a number of men participating. Thus it is that many successful developments come from the laboratory for which it is difficult to award the credit to any individual.

Equipment for industrial research is selected according to the number and scope of our problems, and the amount available is made or acquired in accordance with our needs and the progress of our work. A laboratory for the development of new processes and products should contain all necessary physical and chemical apparatus for the investigation of each fundamental principle involved in the projects under study. Every theory and fact contained in the literature and bearing directly on the problem or related problems is made available to the investigator before work is actually undertaken. We regard this as much a part of our research equipment as the apparatus and desks. Most of these chemical and physical facts and theories have to be checked and confirmed, and the laboratory equipment should be ample to meet these requirements.

Organizing the Experimental Unit

As the results of the laboratory work are completed checked, plotted and discussed, plans are considered for an elaboration of these principles into a small labora

tory apparatus. Confirmation of theories and reasoning at the laboratory desk and further consideration and discussion of results bring us to the point where co-operation is required between the chemists and the engineers.

We believe that the place to start and finish a real chemical engineering problem is in the research laboratory. For this reason our engineers work with and rank with our research chemists. Personal contact and discussion during the laboratory development and close co-operation in the planning of a semi-commercial unit have avoided many misunderstandings and failures.

Our experimental units have for their purpose much more than the checking of the laboratory results obtained by the research chemist. These units are scaled to a size that will permit of a continuous operation over a considerable period in order definitely to establish engineering data for use in the design of commercial units, and to determine capacity, quality of product and materials of construction. It must also produce a sufficient quantity of the product to enable it to be sold and finally to determine if it meets the supreme commercial test, that is, to *stay sold*.

We operate these experimental units from six months to two years, depending upon conditions, changes re-

FIG. 1—CHEMICAL LABORATORY OF RESEARCH PLANT

quired, market tests, etc. During this period, the operation is under the close observation of the research chemists who established the basic data for the process, the engineers who co-operated and designed, and if possible, the mechanics who built the apparatus. Even the plant organization which may ultimately be expected to erect and operate the commercial units, and the sales department which has to sell the product and make it stay sold, are kept in contact with the work.

Incidental to this experimental operation, all questions of quality, specifications, market requirements, containers and natural sales units are determined. The purchasing office becomes familiar with the problems involved in locating, specifying and buying raw materials, the apparent hopelessness of the problem of costs and accounting in the operation becomes clarified for the auditors. And finally the clerks, stenographers and office boys add the new names to their vocabulary and discuss the prospects of the new process with assurance.

Innumerable other elements such as I. C. C. regulations, insurance risk, workman hazards, keeping qualities, etc., are determined so that when commercial units are finally undertaken, all of the elements from design to sale of products are settled and behind us.

Concentration on research problems, based on the needs and requirements of the organization and its policy for development, requires courage and persistence, but it must be regarded as necessary in industrial work. An industrial research laboratory has a different objective from that of the academic institution. We endeavor to achieve constructive results within a limited field, and in a reasonable time, which aim at the building of a plant and the production of a product at a profit. The academic investigator, on the other hand, may choose his problem from the unlimited field and for the purpose of making a contribution to science or of qualifying for a degree. The objective of the industrial investigator is a process and a plant to which he can point with the pride of achievement, whereas the objective of the academic investigator is a contribution to science and publications to which he can with equal fairness point with the pride of authorship. The former measures his success by the amount of factory noise and smoke his work creates, while the latter may modestly acknowledge the cheers of his peers, or may measure his success by the amount of printer's ink he has caused to be consumed.

THE BEGINNINGS AT BALTIMORE

Such a research organization as outlined was established in the fall of 1916 in the industrial outskirts of Baltimore. We selected as a building site a large potato patch and surrounded it with a high fence enclosing several acres. Here we developed what might be called a "research plant." We are inflicted with neither neighbors nor architects. The lighting, heating, ventilation and drainage were planned by and for chemists with the result that we have an abundance of each. Architecturally, as may be observed from Fig. 1, the chemical laboratory is below par, but it is what it was built for.

By the beginning of the year this plant was in full operation, manned by chemists specially qualified by analytical, organic, physical or biochemical training, and brought together from Maine to California with a liberal allowance for intermediate points. The chemists were reinforced with engineers, assistants, mechanics and bottle washers. The specific problem placed before this organization was the development of uses of alcohol and the utilization of the byproducts of the alcohol industry.

The work of the laboratory was soon interrupted by war problems and the entire time of the organization was devoted for over a year to the development and improvement of processes for the production of acetic acid, acetone, methyl acetate, ethylene and solvents for airplane dopes. The acetone process, which at one time supplied 60 per cent of the war requirements for acetone, was discontinued at the signing of the armistice. Methyl acetate and solvents for airplane dopes were no longer in demand and the process for the direct production of acetic acid was abandoned in favor of the byproduct acid. Ethylene has since achieved considerable commercial development as a gas for cutting and welding and as a standard chemical.

Thus at the end of 1918 we were like many other research organizations—going strong, but not in the right direction.

While the surveyors were staking out the site for the laboratory, a competent group of chemists were building up our equipment on the "state of the art." Every literature or patent reference, directly or indirectly related to our problems, in every country and

language was studied, translated if necessary, abstracted, classified, indexed and made available to the laboratory staff. This file now includes over forty thousand references kept strictly up to date. These searchers are in constant contact with the laboratory, supplying them with advance information, helping over the humps and bringing up the rear on patents. The department has since been expanded into a general information service for the entire business, including contemporary progress, commercial development, statistics, foreign relations, etc.

QUALIFICATIONS OF THE GOOD OPERATOR

Good operating chemists and engineers are in a class by themselves. Patience, caution and conservatism are not natural to a chemist who has been trained to visualize the invisible, to theorize and experiment. Too much imagination and inventiveness are qualities which if applied to a production operation will eventually wreck it. We prefer men who are hard headed, poker faced, unimaginative citizens, possessed of an obsession to make the wheels go round.

A good operating man will study every detail of his operation with a view to increasing its efficiency and output. This includes the efficiency and dependability of his operators. Each man, woman or boy in his subunits is studied to determine his or her fitness for the job. They must be made to fit the job or the job made to fit them. This leaves no room on the inside for misfits.

The operating chemist's problems are production, incessant production, quality and costs, including the costs of his losses of equipment, materials and time. If he has a burning desire to investigate something about a going process, let him take his problem to the research laboratory and keep it there till he gets the answer. Let him remember that the business of the plant is to produce and the business of the research laboratory is to experiment and develop, but that it takes a wiser man than he is to make the two function together and avoid the clutches of the sheriff.

PLANT AND OFFICE PERSONNEL

Plant offices are often neglected in spite of the fact that they are capable of being made one of the most necessary and important elements in a plant organization. They should be the connecting link between all internal units of the organization and between the organization as a whole and the public. Some office organizations, if allowed to drift, seem to have a genius for developing a high nuisance value and getting themselves disliked both inside and outside the plant. The exercise of a little common sense and some of the same care on the office personnel and its functions as that used on the development of research or operation will make an office staff what it should be—the pivotal point around which the whole finished organization will smoothly and noiselessly rotate. We believe that accountants, in addition to holding post-mortems on past performances, should supply *live* figures and facts designed to assist, direct and control going operations; that their costs need *not* be a blind assemblage of figures, but that they should reflect a working knowledge of the operation and what the costs ought to be—at least enough knowledge to enable them to get the decimal point in the right place. This policy means that the office becomes a working part of our research engineering construction operating organization and not the "short hour aristocrats" of the plant. Orders, billing and correspondence come in for their share of systematic attention and the "foreign relations" of the organization are handled with a minimum of "alibi building" and "buck passing."

Purchasing agents, in addition to their usual prerogatives of browbeating salesmen, are expected to function as advance agents for research and engineering, to know the stocks of materials and supplies in the

FIG 2—EXPERIMENTAL DISTILLING TOWER AND FERMENTATION LABORATORY

plant and to anticipate balance and look forward. Their job does not end with writing an order and dropping it in the mail, but they are expected to know when and where the goods will be delivered, see to it that they are delivered, that the stuff delivered is what was purchased and, more important, what it wanted, and finally, to see that the man who wants the stuff knows it is in and where it is to be found. This may look like a big contract, but it can be done and is being done wherever purchasing offices function according to our plan.

Having achieved the development of new products and processes and reached the point of production, the largest problem of all is sales. Unless proper attention has been given to the development of sales, which includes the promotion and introduction of the products to the trade, disaster awaits a budding chemical industry.

Sales development is a long and tedious process. It takes time and talent for a new producer to butt into an old market and it takes more time and more talent to introduce new products. New products must be guided through the introductory stages by the research laboratory and especially by those men most responsible for the development. This knowledge and paternal interest must be capitalized in order to furnish salesmen, even those with technical training, with the proper sales points and the necessary enthusiasm.

THE SEASONING PROCESS

General seasoning of a new organization is the most elusive and, therefore, the most interesting problem of them all. It has many discouraging and some mysterious features. Experience and patient hammering seems to be the solution if one can live through it. General plant sense, mechanical horse sense, legal liabilities as applied to purchase, sales and employment contracts, insurance, fire risks, employees, risks and safeguards, do not fall within the training and experience of the young plant chemist or engineer, yet it is

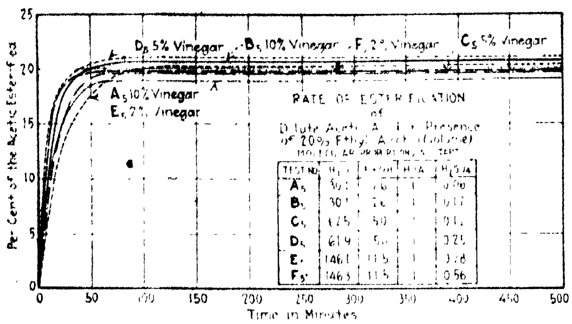


FIG. 3—RATE OF ESTERIFICATION OF DILUTE ACETIC ACID IN PRESENCE OF 20 PER CENT ALCOHOL

incumbent upon the organization as a whole to understand and handle these and many similar problems.

The element of mystery is involved in such things as running a suction pipe 65 ft. into a well, trying to push a loaded conveyor belt, installation of pipe sizes which add 100 per cent to 200 per cent of friction load to the normal head load of a pump, connecting operating units directly to underground sewers, omitting safety valves from steam jacketed equipment and trusting labor to function 100 per cent perfect. To the seasoned factory man, such things are hard to account for. Whatever may be the cause of these apparent lapses, continued hammering, an occasional steam roller and frequently some sad experiences seem slowly to wear down the list. In time men will learn to apply their physics, to think things through, to develop the "high points" in supervision so as to "just happen around" at a critical time, and finally to leave nothing to chance—to hold your aces at all times. No organization will ever be free from seasoning problems so long as we have the human element to deal with, but the "rate of frequency" may be used as a measure of perfection.

Ethyl Acetate

An Example of Organized Production

The foregoing general outline of the methods followed in organizing and preparing for chemical production would seem to require a specific illustration to show how the machinery works. This is probably best furnished by selecting a few steps followed in the development of our process for the continuous production of anhydrous, chemically pure, ethyl acetate directly from dilute solutions of acetic acid and alcohol.

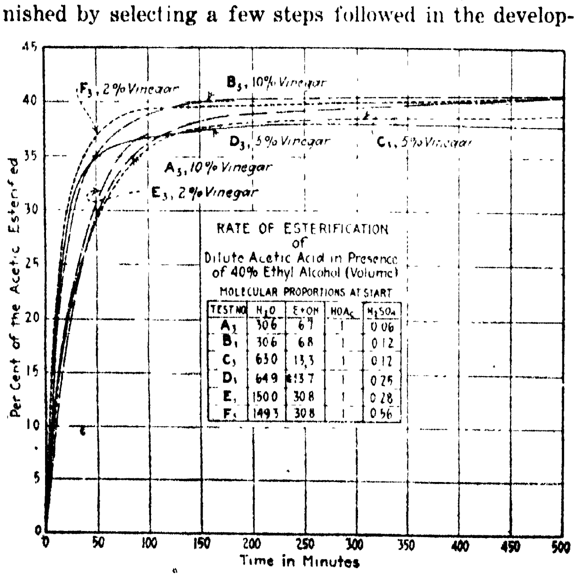

FIG. 4—RATE OF ESTERIFICATION OF DILUTE ACETIC ACID IN PRESENCE OF 40 PER CENT ALCOHOL

The production of ethyl acetate is not new and the literature is full of descriptions of the methods by which it is produced. All of these methods are based upon the theory that high concentration is required to bring about esterification and that in addition to the high concentration, a dehydrating agent, such as sulphuric acid, is necessary. The usual process, as you will recall, is the addition of high proof alcohol and sulphuric acid to dry calcium acetate, usually followed by prolonged refluxing of the mixture. Finally the ethyl acetate formed in the reaction, together with alcohol and acetic acid, is allowed to distill over and

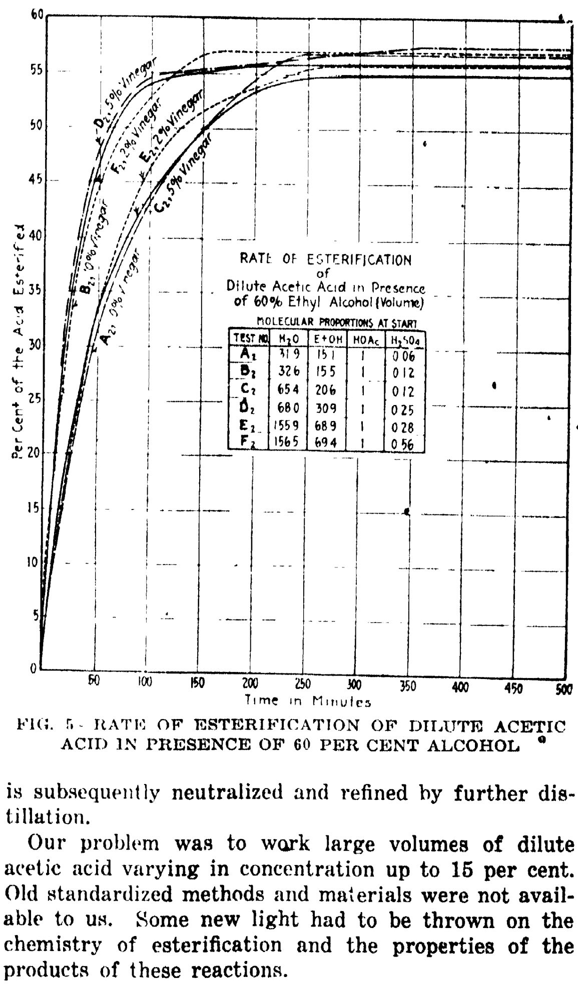

FIG. 5—RATE OF ESTERIFICATION OF DILUTE ACETIC ACID IN PRESENCE OF 60 PER CENT ALCOHOL

is subsequently neutralized and refined by further distillation.

Our problem was to work large volumes of dilute acetic acid varying in concentration up to 15 per cent. Old standardized methods and materials were not available to us. Some new light had to be thrown on the chemistry of esterification and the properties of the products of these reactions.

Following the usual research practice and our abundant references to the state of the art, we made a few cut-and-try experiments on esterification. We played a few "hunches" as it were. These, as usual, resulted in nothing except to exert a sort of gyroscopic effect and to steady the boat. We determined, therefore, to make a basic study of the reactions between alcohol and acetic acid. This study included a careful investigation of the rates of reaction between alcohol and acid, equilibrium conditions, concentration of catalyzers, and various ratios of acetic acid and alcohol. Months were required to complete these investigations, but the facts once established presented an entirely new view of the problem, saved months of time in mistakes, or perhaps avoided final failure.

New Data on Alcohol-Acetic Acid Reaction

The results of these observations were carefully plotted and the following definite conclusions drawn from the facts disclosed:

(1) That there is a very definite reaction between acetic acid and alcohol in dilute solutions.
(2) That sulphuric acid in very low concentrations is an excellent and effective catalyzer for this esterification reaction.
(3) That the rate of reaction is comparatively high and is materially influenced by the concentration of the catalyzer.
(4) That the reaction is in general more than half completed in the first thirty minutes and has reached equilibrium in 150 minutes.
(5) That the equilibrium percentage of acid esterified for all conditions under consideration is determined solely by the concentration of the alcohol in the reacting mixture.
(6) That the old ideas, involving high concentration of the reacting materials, a dehydrator, refluxing, etc., in the ethyl acetate reaction, are a joke.

It is also an easy matter to draw some important deductions from the facts disclosed in these cases:

(1) That if the ester can be removed from the reacting mixture at the rate formed, without disturbing to a material extent the established conditions, it would be possible completely to exhaust the acetic acid in the form of ester.
(2) That having exhausted the acetic acid from the reacting mixture in the form of ester, the alcohol could be recovered by the usual exhausting process and the water residue, having no value, thrown away.
(3) That, assuming the physical facts would permit the removal of the ester from the reacting mixture without altering the conditions favoring the reaction, the operation could be carried on as a batch or as a continuous process.

The answer to the one open question brought out by the second deduction is found in the property of ethyl acetate to form constant boiling mixtures, as might be expected from its kinship to ethyl alcohol—an old offender in this respect. Little note is taken of these constant boiling mixtures in the literature on ethyl acetate processes, but Table I will show their importance to our line of reasoning.

TABLE 1—CONSTANT BOILING MIXTURES OF ETHYL ACETATE—ALCOHOL—WATER

Components	Boiling Point Deg. C	Ester per Cent	Alcohol per Cent	Water per Cent
Ester, Alcohol, Water	70.3	83.2	9.0	7.8
Ester, Water	70.5	91.4	.	8.6
Ester, Alcohol	71.8	69.4	30.6	
Ester	77.2	100.0	.	

All of the curve deductions (see Figs. 3, 4 and 5), including the use of the properties of the constant boiling mixtures, and the relations of these to the solubility mixtures, were promptly put to the test of laboratory apparatus and confirmed.

We then turned to the design of a large scale experimental unit, utilizing some war equipment which was delivered months after the armistice, and junk. It had many misfit elements which did not meet even the calculated requirements of the basic data. It was far from mechanically perfect, and it leaked.

The Semi-Commercial Unit

Nevertheless, this experimental unit served a very valuable purpose. It operated for several months and produced a product at a profit. It gave the engineers an opportunity to study the materials of construction, and the design. It gave the chemists a chance to find out some things about continuous operations of this character, which they had not heretofore known, for example: They expected to produce ester of high quality and free from aldehydes. They were unsuccessful in this until they discovered that a small amount of aldehyde was formed in the operation and carried into the finished product. The experimental unit gave opportunity to introduce a minor change which resulted in the accumulation of the aldehyde and its complete separation from the final product.

The experimental apparatus had a capacity of 300 to 400 gallons per day and was operated on a 24-hr. basis continuously for months at a time. During this period, the engineers had every opportunity to study the performance of the apparatus and to design a new machine embodying the ideal requirements as developed in the original investigations, and at the same time meeting the operating requirements as developed in the large scale experimental apparatus. In the meatnime, the market test showed the product of this process to be

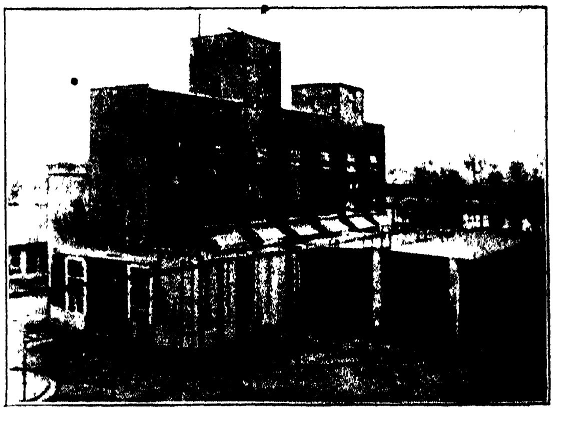

FIG. 6—ETHYL ACETATE PLANT

exceptionally good. There was no difficulty in selling it or making it stay sold, and the demand for larger production was constantly increasing. We had reached this point in our work when one of our former associates, for whose opinions we had the greatest respect, but who had not kept up to date on our work, advised us that in his opinion we were "trying to drive a pile, a railroad spike and a tack with the same hammer in one operation."

The large scale designs were finally completed, put in the shops, erected and put into operation. (Fig. 6 shows plant.) This machine was kept under continuous observation by the research laboratory and the engineers for a period of over a year; daily reports in the form of operating logs were kept, not only for the guidance of the plant operating men, but also for the research chemists and engineers. These reports formed the basis of a subsequent complete re-analysis of the process and plant by the research laboratory for the purpose of establishing all facts and data that had developed in subsequent construction and operation, with a view to improving the design, materials of construction, operating features, etc.

The changes found necessary as a result of this re-investigation were very minor, and a second unit is now ready for operation which is almost an exact duplicate of the first. The monthly production of anhydrous chemically pure ethyl acetate by the continuous esterification of dilute acetic acid by this process is now over 150,000 gallons.

Research Bureau Laboratory Standard Steel Car Co.

BY RICHARD RIMBACH

THE Research Bureau Laboratory, located on the ground floor of the recently completed Cafeteria Building at the plant at Butler, Pa., embodies some of the best features of a number of laboratories visited by the metallurgist. Much of the apparatus, furniture and other equipment was specially constructed to his designs and specifications. In most cases this equipment was built in our own shops.

The laboratory has five units: A physical testing laboratory, a heat-treating laboratory, an experimental machine shop, a metallographic laboratory and a chemical laboratory. The disposition and character of the equipment as planned and installed insure the execution of all work with due economy of time and effort.

The physical testing laboratory, the heat-treating laboratory and the machine shop were combined, because this arrangement promises facility of operation.

The physical laboratory is equipped for all kinds of physical tests. It contains the following testing machines: A 200,000-ft. automatic and autographic universal testing machine; a 60,000-in.-lb. automatic and autographic torsion machine; a cold bend machine; a repeated impact machine; a vibratory machine; a slip abrasion machine; a 120-ft.-lb. combined impact tension and cantilever notched bar bar-testing machine.

The heat-treating equipment is modern in every respect. The arrangement is excellent for research work, such as case-hardening and other heat-treating experiments. The equipment consists of two electric muffle furnaces and an electric carbon resistance high-speed furnace. A high-resistance double-scale wall mounting indicating pyrometer with an eight-point switch is used for reading the temperatures of the furnaces. The quenching is done in four tanks, each 2x3x25 ft. Two of the tanks are for oil, one for brine and the other for water. These are provided with wire baskets so that the specimens may be dropped as soon as they have been quenched. Water, air and steam jets are also arranged for hardening. A hood for taking away the fumes and heat is over all furnaces. A Brinell machine is used for checking the heat-treatments, as is also a scleroscope.

The machine shop is equipped with the machines necessary for the sampling and preparation of tests for physical testing, chemical and microscopic analysis.

METALLOGRAPHIC AND CHEMICAL LABORATORIES

The metallographic laboratory also serves as the balance room. It is equipped with thoroughly up-to-date apparatus, including an optical bench. The microscope is an important feature of the modern laboratory and no pains have been spared to make this one complete in every respect. The optical bench is mounted on a stand of drawers in which the photographic plates are filed. Experiments in pyrometry can be carried on in this room. For this purpose a work bench runs along one wall. The critical point machine is set up at one end of this work bench. The balance table is placed so as to be most convenient to the adjoining chemical laboratory.

The chemical laboratory has the equipment of a first-class analytical laboratory. The work tables are composed of alberene stone mounted on drawer and cupboard units. A hood unit 12 ft. long and 3 ft. wide is provided, the working table of which is covered with alberene stone. The hoods have not only the customary upper draft into the stack but also a lower draft. This draft is sufficient to pull out heavy fumes, which otherwise get into the room. It is supplied by an acid fume-resistant exhaust blower. The hood unit is divided into four compartments. One compartment is used for sulphur determination apparatus, one for phosphorus, one for dissolving samples and the last for testing fuels, oils and gases. Nearly all hot acid solutions are cooled under the hoods, and in a large measure the atmosphere of the laboratory is quite free from acid fumes. A large cabinet is placed at one end of the laboratory, for storing chemicals and glassware which are not used daily.

A shower bath head is placed in the chemical laboratory for extinguishing burning clothing or for diluting corrosive liquid splashes. It is provided with a chain fastened to a quarter turn valve so that the water may be released without difficulty in time of accidents. No drain is provided in the floor, as the use of this shower should be infrequent.

The service is piped above the tables and in the hoods. The tables and hoods are provided with numerous electric power plugs for the operation of motors, ovens and the like. The piping system comprises drains, oxygen, hot and cold water, compressed air, vacuum, gas, distilled water and high- and low-pressure steam. The pipes and fittings are painted with distinctive colors denoting their use, which makes it an easy matter to locate trouble. The color scheme used is given below:

Service	Color of Pipe	Color of Fittings
Acetylene	Black	Black
Compressed air	Yellow	Black
Electricity, 110 v., d.c.	Black	Red
Electricity, 220 v., d.c.	Black	Yellow
Electricity, 440 v., a.c.	Black	Green
Gas	Blue	Gray
Hydrogen	Blue	Blue
Oxygen	Yellow	Yellow
Pyrometers	Black	Gray
Vacuum	Green	Green
Water, cold	White	White
Water, hot	White	Black
Water, distilled	Glass	Rubber
Waste and sewage	Gray	Gray

The vacuum is furnished by a small vacuum pump, which starts and stops automatically.

There is also a storeroom for heavy chemicals, apparatus and miscellaneous supplies. This storeroom has a card system which is kept up to date, making it possible to tell the amount of material on hand at any time.

New Uses for Grain Sorghums

The grain sorghums, a comparatively new crop in the United States raised largely only for the feeding of farm animals, are now being used in increasing quantities for human food and various industrial purposes, according to the United States Department of Agriculture, and are receiving attention from the manufacturers of alcohol and starch. Feterita and milo, which contain on an average 65 per cent of starch, seem to be especially suitable as raw material for the manufacture of high-grade starch by commercial processes.

The results of a study on the physical characteristics and the chemical composition of milo and feterita have just been published in Department Bulletin 1129, by George L. Bidwell, Leslie E. Bopst, and John D. Bowling, Bureau of Chemistry. This study was made to provide a basis for the utilization of grain sorghums in the manufacture of starch and feeding stuffs, and to furnish data for engineers who may be called upon to design machinery for milling, all of which data are included in this bulletin.

Effect of Temperature On the Mechanical and Microscopic Properties of Steel

By George C. Priester and Oscar E. Harder

Assistant Professor Mathematics and Mechanics, and Associate Professor Metallography, University of Minnesota.

Properties of a Low-Carbon Steel in the Blue Heat Range Are Inherent to That Temperature and Are Not Duplicated When Same Metal Is Tested at Room Temperature After a Corresponding Tempering

THIS investigation was instituted early in 1920, and had for its purpose a study of the mechanical properties of steels at elevated temperatures, the properties of these same steels at ordinary temperature after having been heated to various drawing temperatures, and, finally, the correlation, in so far as possible, of these properties with the microstructure of the steels.

Previous Investigations

Recently published investigations on this subject include those by French,[1] MacPherran,[2] Spooner[3] and D'Arcambal.[4] French first investigated boiler plate of firebox and marine grades with carbon contents of 0.19 and 0.25 per cent respectively.

As a means of comparing these results Table I has been prepared. In it a ratio has been figured between the properties of these steels at room temperature and at that temperature which showed the maximum tensile strength. Some calculations are only approximate, because the values had to be taken from the published curves.

TABLE I RELATION OF MECHANICAL PROPERTIES AT HIGH AND ROOM TEMPERATURE

Investigator	Carbon, Per Cent	Tensile Strength	Propor Limit	Yield Point	Red of Area	Elongation
H. J. French	0 19	1 13	0 66		0 80	0 68
	0 25	1 09	0 72		0 75	0 56
	0 38	1 10	0 73	0 54	0 54	0 74
Authors	0 16	0 98	0 89	0 98	0 92	0 96
R. S. MacPherran	0 19	1 22			0 83	0 57
	0 09	1 33		0 67	0 81	0 58
	0 41	1 03			0 85	0 53
	0 53	1 14		0 90	0 70	0 70
A. P. Spooner	0 10	1 25		0 78	0 85	0 66

It will be observed that the present authors have obtained a lower ratio for the tensile strength, but higher ratios for the other values. This can probably be attributed to the different heat-treatments, since we have tested the steel at room temperature in the hardened conditions, whereas other investigators have used annealed or drawn steels for their tests at room temperature.

Scope of the Investigation

The present investigation has included the following: Development of apparatus for determining the mechanical properties of steel at elevated temperatures; tests on hardened 0.16 per cent carbon steel to determine the maximum stress, proportional limit, yield point, reduction of area, and elongation at temperatures from 20 to 600 deg. C.; determination of these same properties on specimens which had been hardened, drawn at various temperatures from 100 to 600 deg. C. and tested at ordinary temperature; and the impact properties of specimens tested at ordinary temperature after hardening and subsequently drawing at various temperatures. There is also included the Brinell and scleroscope hardness values on the drawn specimens and the microscopic examination.

Hot-rolled steel ¾-in. diameter was used of the following chemical composition: C 0.16, Mn 0.46, S 0.034, P 0.009. All specimens were annealed after machining and before hardening in order to give a uniform structure. The various heat-treatments are discussed under the particular test to which they apply.

Tests at Elevated Temperatures

In order to make tests at elevated temperatures, a special apparatus was developed, a sketch of which is shown in Fig. 1. The temperature of the specimen was measured by a carefully calibrated thermocouple, the hot junction of which was clamped in contact with the lower shoulder of the specimen. The specimen was gradually heated to the desired temperature by means of the electric furnace and was held at that temperature for 30 minutes to establish thermal equilibrium. Under these conditions it is believed that any heat changes which took place during the testing of the specimen are negligible. It is believed that there can be no

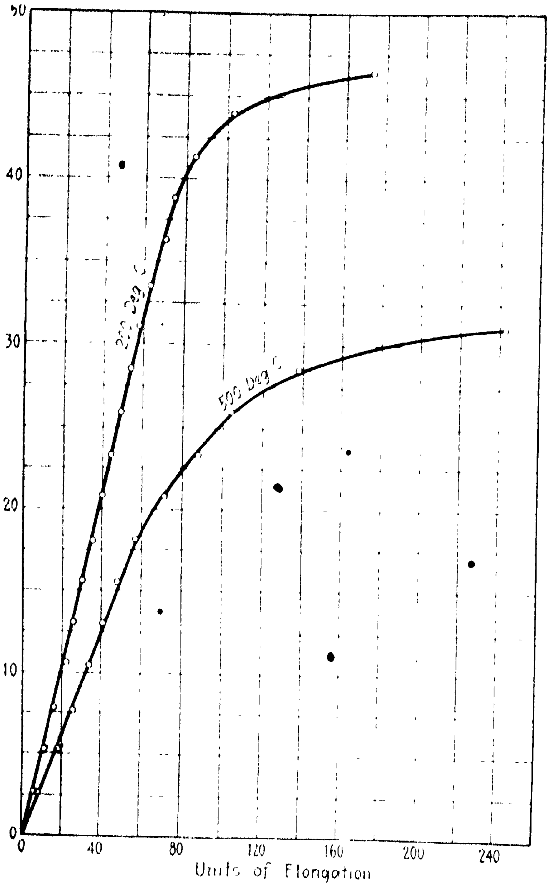

FIG. 2—TYPICAL STRESS-STRAIN CURVES, SPECIMENS QUENCHED FROM 910 DEG. C. AND THEN TESTED AT THE TEMPERATURES NOTED

question about the accuracy of the temperature measurements for these tests.

It will be observed from the figure that the extension was measured by means of two Ames dials on opposite sides of the specimen. The character of the stress-strain diagram and incidentally the care with which this work has been done are shown in two typical curves in Fig. 2. The specimen used in making tests at elevated temperatures is also shown in Fig. 1. The extensions, as measured, doubtless are for a longer gage length than 2 in., but this condition would only change the slope of the stress-strain curve, thus making it impossible to calculate accurately the modulus of elasticity, but would not affect any of the data herein reported.

Data in Table II show the results of the tests made on this steel at temperatures from 20 to 600 deg. C. The heat-treatments which these steels received before testing should be noted,* because some investigators have tested steels without any heat-treatment, and usually they have annealed or drawn the specimen at a temperature above that at which it was to be tested before heating it for the test at elevated temperature. Our steel had been given an anneal and then hardened before heating for the test at elevated temeprature. It had not been drawn before testing. This probably accounts for the fact that maximum stress, yield point

TABLE II—EFFECT OF TEMPERATURE ON THE MECHANICAL PROPERTIES OF STEEL

7A	600	10 300	19,300	23,200	96 3	38.0

or proportional limit never exceeds the values obtained at ordinary temperature. However, there is a well-marked maximum in these curves clearly shown in Fig. 3 which is in good agreement with results found in previous investigations. The character of the fracture of these test specimens seems to be rather significant and these fractures are shown arranged in order of the increase in temperature from left to right in Fig. 4. The marked decrease in the maximum stress, yield point and proportional limit begins at about 350 deg. C., and this seems to be in general agreement with the breakdown in the microstructure (Figs. 6 to 13.)

Quenched and Tempered Steels

Specimens used for testing this steel after tempering correspond to the A.S.T.M. standard. Heat-treatment of the machined bar consisted in annealing 1 hour at 910 deg. C., furnace cooling; hardening in ice water after 30 minutes' soaking at 910 deg. C., then heating to the various drawing temperatures, holding at that temperature for ½ hour and then cooling in air to room temperature. Results of these tests are shown in Fig. 5.

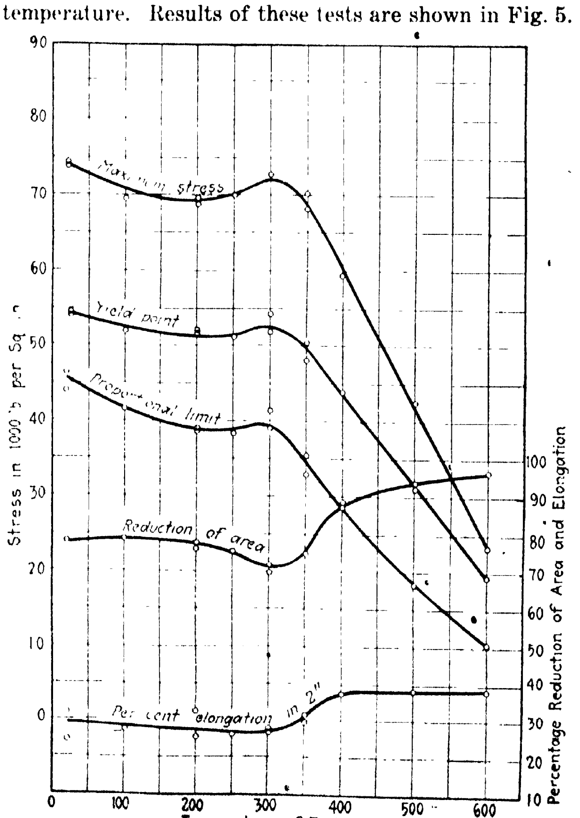

FIG. 3—MECHANICAL PROPERTIES OF QUENCHED 0.16 C. STEEL AT HIGH TEMPERATURES

*The test pieces were machined, heated to 910 deg. C., held for 1 hour, cooled slowly in the furnace, reheated to 910 deg. C., held for 30 minutes, then quenched in ice water. The specimens were then placed in a testing machine as shown in Fig. 1, heated to the temperature shown, held at that temperature ½ hour and tested at that temperature.

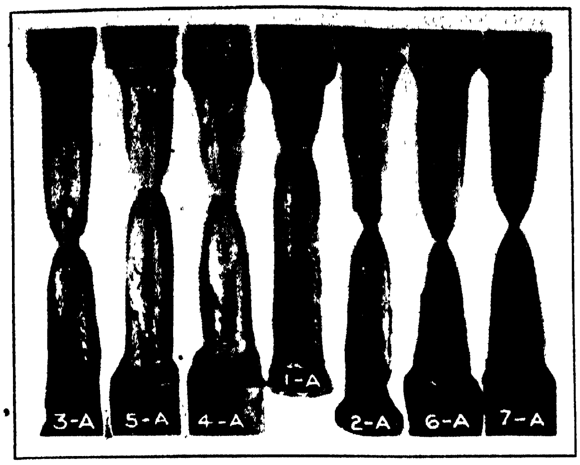

FIG. 4—FRACTURE OF SPECIMENS BROKEN AT HIGH TEMPERATURE (ABOUT HALF SIZE)

The mechanical properties—maximum stress, yield point, proportional limit, reduction of area and elongation—are approximately straight line functions of the drawing temperature. There are no maximum and minimum points which result from the steel having been drawn at 300 deg. C. This leads to the conclusion that the maxima and minima observed when the tests are made at elevated temperatures are due to the temperature at which the tests are made and not to the fact that the steel has been drawn at certain temperatures.

Impact Properties—The impact test data are shown in Table III. Tensile test specimens were turned down to 0.236 in diameter between gage marks; the specimen

TABLE III—EFFECT OF DRAWING TEMPERATURE ON THE IMPACT PROPERTIES OF STEEL

600	73.2	21.0	64.7	3,000	20.4	948
600A	74.3	23.5	67.0	3,240	20.3	942

was 4 in. long and the $\frac{3}{8}$-in. shoulders at each end were threaded clear up to the fillet. The results are erratic, but seem to indicate that the impact tensile, reduction of area and elongation show a minimum after a draw at 100 deg. C. There is then an increase in these properties up to about 500 deg. C. with possibly a little falling off after a draw at 600 deg. C.

Notched bar tests show a gradual increase with the increase in drawing temperature. The test pieces were notched before hardening (which is not the usual practice). They were 10 mm. square, 55 mm. long, notched at the center half way through. The notch was 1 mm. wide and had a round bottom.

Brinell and Scleroscope Hardness — Brinell and scleroscope hardness tests were made on the specimens which had been tested at elevated temperatures for

TABLE IV—EFFECT OF DRAWING TEMPERATURE ON THE HARDNESS OF STEEL

their tensile properties. They had not only been drawn at the various temperatures shown but had also been stressed in tension at those temperatures. The data from the hardness tests are given in Table IV and are shown graphically in Fig. 5. The results are averages of at least five tests on the individual specimen. The effects of drawing temperatures on these values are in general agreement with the effects on the tensile properties of these specimens at high temperatures (shown in Fig. 3) rather than when tested in tension after a draw. However, there are observed peaks in the curves for the Brinell and scleroscope hardness curves at draws of 200 and 350 deg. C. respectively. No explanation is offered for this phenomenon.

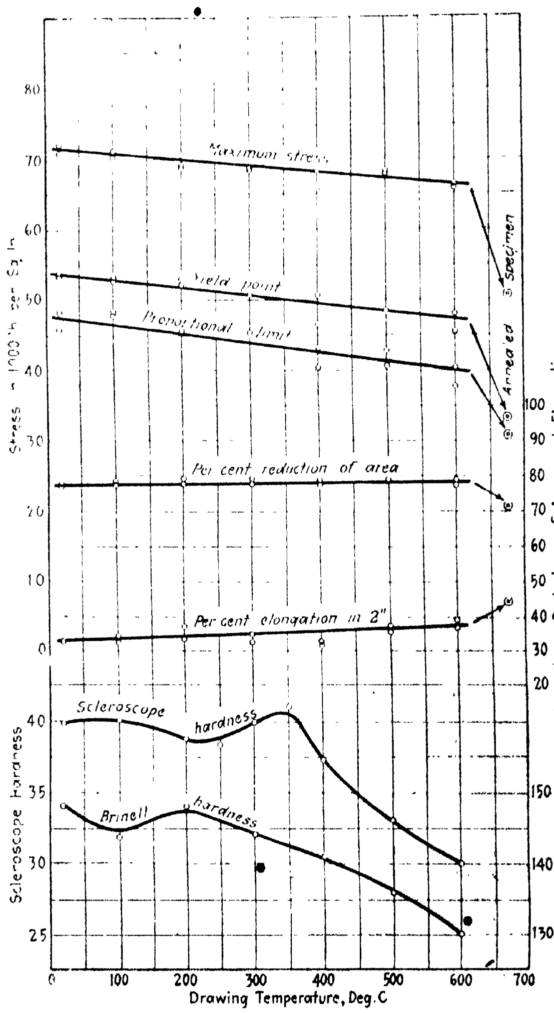

FIG. 5—PROPERTIES OF QUENCHED AND TEMPERED 0.16 C. STEEL

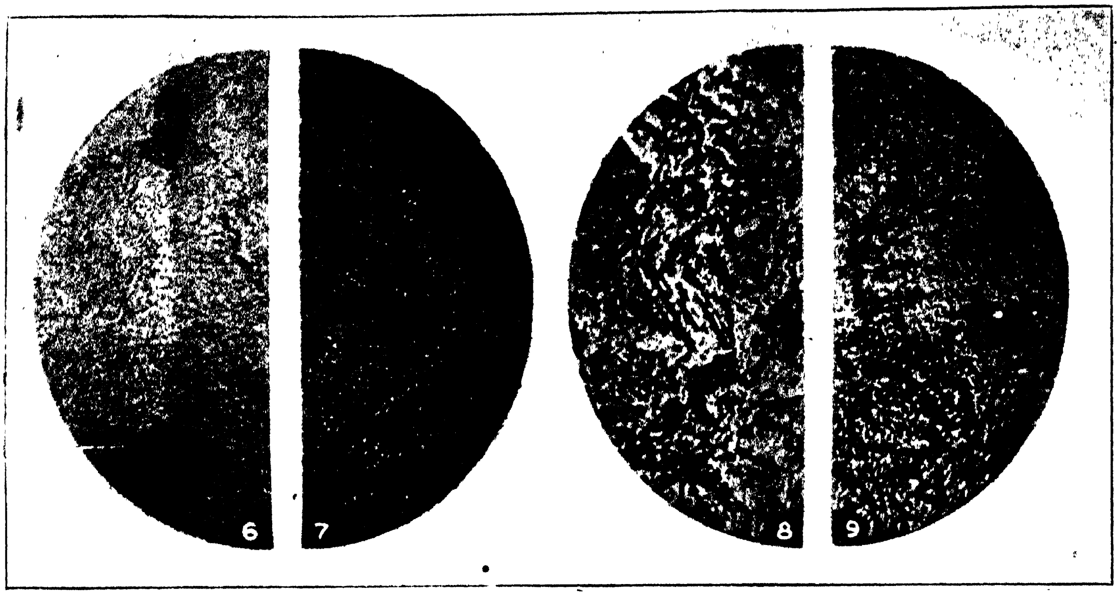


FIGS. 6 TO 9—STRUCTURE OF STEEL. ETCHED WITH PICRIC ACID. × 1,000
Fig. 6—Annealed. Fig. 7—Quenched from 910 deg. C. Fig. 8—Drawn at 100 deg. C. Fig. 9—Drawn at 200 deg. C.

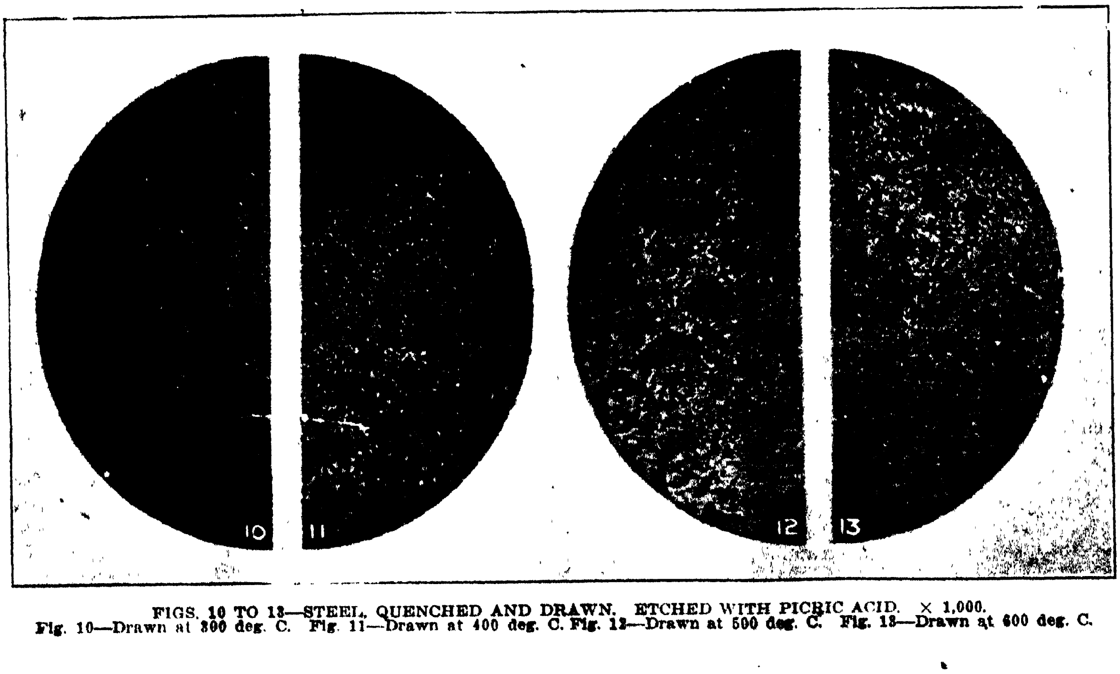
Microscopic Examination—Microscopic examinations of the specimens which had been drawn at various temperatures show first of all that the hardened specimens still contained some free ferrite and are reproduced in Figs. 6 to 14 inclusive. The amount and distribution of ferrite seems to be fairly uniform in the different specimens. There is an indication of a breakdown in the hardened areas at the higher draw, particularly at 400 to 600 deg. C. It is difficult to get satisfactory etches on hardened steel of this low carbon content.

CONCLUSIONS

(1) Plain carbon steel containing 0.16 per cent carbon, when tested at temperatures ranging from 20 to 600 deg. C., shows a maximum in the maximum stress, yield point and proportional limit curves at about 300 deg. C.; however, these values do not exceed the corresponding values at 20 deg. C. It shows a minimum in the reduction of area curve at approximately this same temperature, with a less pronounced minimum in the elongation curve.

(2) These changes in the physical properties are due to the temperature at which the test is made and are not the result of the steel having been drawn or tempered at a certain temperature. This is shown by the fact that when this steel is drawn, then cooled to ordinary temperature and tested, there is no maximum or minimum observed in the curves.

(3) Above about 300 deg. C. the minimum stress, yield point and proportional limit decrease almost as a straight line function of the temperature at which



FIGS. 10 TO 13—STEEL, QUENCHED AND DRAWN. ETCHED WITH PICRIC ACID. × 1,000.
Fig. 10—Drawn at 300 deg. C. Fig. 11—Drawn at 400 deg. C. Fig. 12—Drawn at 500 deg. C. Fig. 13—Drawn at 600 deg. C.

the test is made, and the effect on the maximum stress is the most pronounced. There is a corresponding increase in the reduction of area and elongation, but the elongation is approximately constant above 400 deg. C.

(4) The impact toughness increases with the drawing temperature and appears to be nearly a straight line function of the drawing temperature.

The results of the impact tensile tests show a slight decrease in the tensile strength, reduction of area and elongation for specimens drawn at 100 deg. C. At higher drawing temperatures these values increase with increase in the drawing temperature.

(5) Microscopic examination shows changes in the microstructure which correspond to the changes in the mechanical properties at the higher temperatures (400 to 600 deg. C.), but do not seem to throw any light on maximum and minimum points in the curves for tests at 300 deg. C.

Recent Work on the Separation of Isotopes*

THE SEPARATION of isotopes is of timely interest, inasmuch as Dr. Aston and Professor Soddy have just been awarded the Nobel prize for their work in this connection. It was Soddy who gave the name to isotopes and who began his work in 1914. Aston's work is later, and has to do with those of common elements.

It would be as difficult to answer the question "what is an isotope?" as it would be to expound the problem "what is a scissor?" or "what is a trouser?" They are indeed atomic twins, triplets, quadruplets and even sextuplets and octuplets. Isotopes of an element have substantially all properties in common except atomic weight. Isotopes of chlorine have, for example, masses respectively of 35 and 37. Six have been found of mercury and eight of tin. On the other hand, oxygen nitrogen, carbon and hydrogen appear to be homogeneous, and have only one atomic weight; to be, therefore, without isotopes.

The whole thing is revolutionary, in that it attacks the chemist in his most sensitive spot, where his most painstaking work has been carried on—his table of atomic weights. It makes his meticulous fractions mere averages of mixtures of isotopes of which the mass of each is indicated by a whole number. On the other hand, it connects up and coincides in a remarkable manner with the Lewis-Langmuir theory of atomic and molecular structures. Aston's deductions, like Langmuir's, may be wrong, but it is hard to deny them in the face of such an overwhelming flood of coincidences as is found in support of them.

Aston's Process of Separation

The Aston method of procedure consists, first in obtaining the positive rays of a given material by the adoption of a modification of Sir J. J. Thomson's method of positive ray analysis. The material is first ionized by X-rays and passed through a fine slit, giving a narrow ribbon of rays. These are then passed between positive and negative poles which deflect the positive rays in the direction of the negative pole. Passing now through a diaphragm the positive rays are again deflected by a magnet, so that they strike a photographic plate. If, then, all rays have the same mass they should strike the plate at the same spot. Aston's experiments show this to be the case with elements which have atomic masses of whole numbers based on oxygen as 16. An oxygen gives only a single mark. Those having fractional atomic weights give more than one line, as, for instance, chlorine which gives one line at exactly 35 and another at 37, the line at 35 being three times as strong as that at 37. Neon shows a line at 20 and one at 22, but that at 20 is ten times brighter than the one at 22. He tested out carbon monoxide in the same way, and got bands at 28, at 12 and at 16. Carbon and oxygen show no isotopes, but the undissociated positively charged CO went just where it belonged, to 28. He made a great number of tests and reached the conclusion already given, that with oxygen as 16 every element that shows a fractional atomic weight consists of isotopes having masses of whole numbers, while every element with a whole number for its atomic weight with oxygen as 16, is homogeneous, i.e., it has no isotopes.

The Ionic Migration Method

The principle of the moving boundary is here being utilized. An agar-agar gel containing a chloride is inserted as a short middle section in a long horizontal tube, being preceded by a gel containing a faster anion (hydroxide ion) and followed by a gel containing a slower anion (acetate ion). When a current is passed, the boundaries between the solutions remain perfectly sharp, and the chloride moves slowly toward the anode. Now tubes of hydroxide gel are inserted before it reaches its goal, and after it has traveled, say, 100 ft., the chloride gel is sectioned and analyzed. If Cl(35 and Cl(37) possess different mobilities, the front section should contain only the one isotope, the second section only the other.

The Discharge Potential Method

Although the free energy charges involved in the separation of an electron from isotopic ions such as Cl(35) and Cl(37) are not necessarily identical, owing to the different constitutions of their nuclei, it is unlikely that the discharge potentials of the reaction: $2\,Cl^- \rightarrow Cl_2 + 2$ minus will be *appreciably* different in the two cases, when expressed in volts. What is more important than any possible *intrinsic* difference is the fact that in the natural isotopic mixture the concentration of $Cl^-(35)$ is more than 3 times that of $Cl^-(37)$. Provided the familiar Nernst E.M.F. equation applies, therefore, the discharge potentials of the two ions *in any solution* should differ by about 0.03 volts. If now we can adjust our current so that it is just above the decomposition potential of one ion, and just below that of the other, and if we can withdraw the discharged products immediately, then a perfect separation should be possible. Possibly the utmost that will be obtainable in practice, will be an "electrolytic fractionation."

The experimental details are now being developed and perfected, before actual runs are made. Mercury, magnesium and lithium are under investigation in the connection, as well as chlorine.

The Freezing Point Method

Although attempts to separate other isotopes by analogous methods have not succeeded in the past, it is possible that in an extreme case such as Li(6) and Li(7), where the atomic masses vary by 16 per cent, an appreciable difference in the points of fusion of the pure isotopes will exist, and so permit a separation by fractional crystallization. This method is being tested out at the present time, with lithium and potassium.

*Résumé of a talk by Dr. James Kendall, of Columbia University, before the New York Section of the American Chemical Society Dec. 8, 1922.

Ethylene as a Source of Alcohol

A Study of the Distillation Gases Yielded by Trent Amalgams, With Special Reference to Their Unsaturated Constituents*

By J. D. Davis
Research Chemist, Pittsburgh Experiment Station
U. S. Bureau of Mines

SIXTY years ago M. Berthelot found that ethylene could be selectively absorbed from gaseous mixtures by concentrated sulphuric acid and that the compound formed by the chemical union of the gas and acid was readily decomposed by heating with water, yielding ethyl alcohol. Only within the last few years has there been any attempt to make use of this discovery technically. Bury[1] working in England at the Skinningrove Iron Works and on a commercial scale, developed a technical method for converting the ethylene of coke oven gas into alcohol. With a gas containing less than 3 per cent of ethylene, he obtained a yield of 1.6 gal of alcohol per ton of coal carbonized.

De Loisy[2] perfected a technical method for treatment of coke-oven gas for alcohol. Evidently this work was carried out on a semi-commercial scale. His method is based on the use of catalytic agents for hastening the absorption of ethylene by sulphuric acid. He uses part of the spent acid for drying the gases and part for the manufacture of ammonium sulphate. Excess acid is reconcentrated by waste heat. Others have worked on the problem, but so far there has been no large recovery of ethylene from coke-oven gases. The chief difficulty seems to lie in the low efficiency (about 50 per cent) of methods and the relatively low concentrations of ethylene in the gases treated. Gas from Trent amalgam[3] contains much larger percentages of ethylene than does coke-oven gas, as will presently be shown, and if it should ever prove practical to treat industrial gas for alcohol, this gas would offer attractive possibilities.

Carbonizing Trent Amalgams

The method used here to carbonize the amalgams differs from any now used for the commercial carbonization of coal. In ordinary practice, coal charges are distilled at all temperatures from the decomposition point of the coal to the highest retort temperature, and no definite temperature can be fixed on as the temperature of distillation. With the method here used, the distillation range was made narrow. This was effected by feeding the charge regularly into a retort kept at constant temperature—that is, the predetermined distillation temperature. Distillations were conducted at temperatures 400, 500, 600, 700 and 800 deg. C., and the gases evolved were measured and analyzed. Samples of the coal and oil used to prepare the amalgams were distilled under the same conditions as were the amalgams for purposes of comparison.

Loss	1.31
Specific gravity of the oil at 20 deg. C.	0.868

Experimental Results

The materials used in the experiments were Illinois coal obtained from the Big Muddy Coal & Iron Co., Herrin, Ill., and an asphaltic base fuel oil. An analysis of the coal is given in Table I, which also shows the fractionation results for the oil. Table II gives the analyses of gases evolved from amalgam, coal and oil at temperatures 400, 500, 600, 700 and 800 deg. C., together with total yields of gas and light oils scrubbed from the gas. Results for the 700 deg. amalgam run are not reported, owing to the fact that precipitated carbon clogged the mains and rendered the gas samples taken of doubtful value.

In general, the oils give higher yields and richer gases; the amalgams give somewhat less gas of poorer quality; and the coals give the lowest yields and the poorest gas. It is an interesting fact that the run at 800 deg. C., (with continuous feed) gave almost as much gas for the amalgam as for the oil, and gave a gas of slightly better quality. It thus appears that at

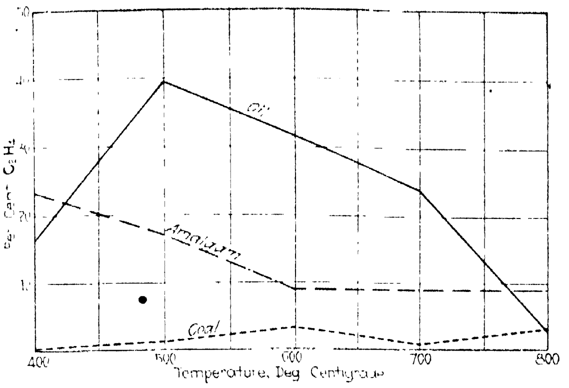

FIG. 1—PER CENT OF ETHYLENE IN GASES FROM OIL, AMALGAM AND COAL

this temperature Trent amalgam is just as good material for making commercial oil gas as the oil itself. The amalgam would of course be the cheaper, and further, it will be noted that under these conditions more oil was scrubbed from the amalgam gas than from the oil gas. Of course if a rich oil gas is wanted, the best procedure is to crack the straight oil at a lower temperature.

The percentages of oxygen-containing gases for the coals and amalgams are considered somewhat high. This is due partly to the method of feeding the retort and partly to the fact that the coal used was of high oxygen content. As for the first cause, the charge fed was finely divided, and must have carried into the retort a fair amount of adsorbed air.

Unsaturated Gases The percentages of unsaturated gases are uniformly higher for the oil except with the run at 800 deg. C., where the amalgam gives the highest percentages. The coals give the lowest percentages of unsaturated gases, but slightly higher, perhaps, than would be obtained by commercial methods of carbonization The amounts of these bodies found for the amalgams are intermediate between those for the oil and coal. Unsaturated gas is reported here as ethylene (C_2H_4), and it is probable that 95 per cent of it actually was ethylene. Especially is this true when it is considered that the gas had passed a charcoal scrubber, which would have a tendency to remove heavier gases.

Yields of Unsaturated Gases From Amalgams—Table III gives the yields of unsaturated gases from amalgams at the corresponding temperatures of distillation,

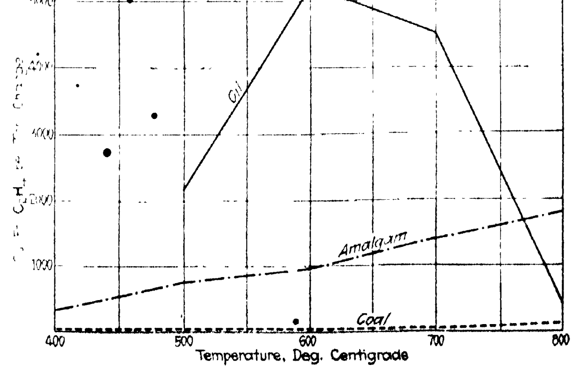

FIG. 2—YIELD OF ETHYLENE IN CU.FT. PER TON OF CHARGE

TABLE III—YIELDS AND ALCOHOL EQUIVALENTS OF UNSATURATED GASES FROM AMALGAMS

Temp Deg C.	C_2H_4 Per Cent	Total Gas Cu Ft	C_2H_4 Cu Ft.	Alcohol Equivalent Gal. Per Ton
400	23 4	750	172	3.1
500	17 0	4,400	760	13.8
600	8 8	10,850	955	17 3
800	8 9	19,800	1,760	32 0

and their equivalents in alcohol, assuming complete recovery. Figs. 1 and 2 show the data graphically. As a basis of comparison of yields we may take Bury's[1] figure of 1.6 gal. of absolute alcohol per ton of coal charged in byproduct ovens. Assuming a 50 per cent recovery, this would mean a possible yield of only 3.2 gal. of absolute alcohol per ton of coal from coke-oven gas, whereas from Trent gas there is possibly from 3 to 32 gal. per ton of amalgam charged It would thus seem that Trent gas is ideal (second only to oil gas) for the application of an alcohol recovery process.

Recovery of Ethylene as Alcohol So far it has not been possible to recover from coke-oven gas more than 50 per cent of ethylene contained as alcohol, but it would undoubtedly be possible to improve this figure considerably by research. The problem offers possibilities, particularly in connection with the rich Trent gas For example, De Loisy found that he could increase considerably the speed of absorption of ethylene by sulphuric acid through the use of catalytic agents, and thereby increase the recovery of alcohol.

Loss of Heating Value Through Removal of Ethylene From Gases Table IV shows that the loss of heating value suffered by Trent amalgam gases on removal of the ethylene is not an important consideration. They are rich gases to start with, and the removal of ethylene, although that gas has a high heating value, does not bring their heating value below that of the best industrial gases.

TABLE IV—EFFECT OF REMOVAL OF ETHYLENE ON THE HEATING VALUES OF TRENT AMALGAM GASES

Distillation Temperature, Deg. C.	B.t.u. Per Cu Ft Raw Gas	B.t.u. Per Cu Ft Scrubbed Gas
400	1,000	798
500	936	795
600	726	639
800	757	671

It may be stated further that the ethylene in the composite gas has a market value much below that which it would have as pure gas. For example, (see Table III) a 600 deg. distillation will yield 10,850 cu.ft. of composite gas, 955 cu.ft. of which is ethylene. The ethylene if recovered commercially pure would be worth 1 cent per cubic foot, or \$9.55, whereas all the gas (at 50 cents per 100) would be worth about \$5.40.

Flaky Fractures in Tool Steel

In connection with an extended investigation of high-speed tool steels now under way at the Bureau of Standards a number of treatments were applied to a single heat of high tungsten, low vanadium steel to determine whether so-called fish scale or flaky fractures could be produced intentionally, irrespective of the quality of metal as has been claimed. Normal fractures were obtained, however, in all cases, but these tests will be supplemented by further work with steels of questionable quality.

The Low-Temperature Carbonization of Coal

III.—The Clinchfield Carbocoal Plant

By Harry A. Curtis and Earle E. Daughton

THE Carbocoal process, as finally developed at Irvington, N. J., consisted of the following steps:

1. Crushing the coal and carbonizing it at a relatively low temperature in primary retorts provided with means for agitating the coal and advancing it continuously through the retorts.

2. Grinding the carbon residue, fluxing it with pitch, and briquetting.

3. Carbonizing the briquets at a relatively high temperature in secondary retorts to harden them and render them smokeless. The experimental plant at Irvington grew to be a semi-commercial installation before the work there was discontinued, but the plant was never put on a purely production basis. In September, 1918, ground was broken for a commercial Carbocoal plant at Clinchfield, Va. This plant was a government war project, but after the armistice construction was completed by the International Coal Products Corporation and the plant finally put into operation late in June, 1920. Not all of the units were finished at this time, but they were completed during the next few months.

General Arrangement and Equipment of the Plant

The Clinchfield Carbocoal plant has been described in several technical journals during the past 2 years.[1] There will therefore be included in the present article only such brief mention of the general features of the plant as will contribute to an understanding of the operating problems discussed later.

The general layout of the plant is shown diagrammatically in Fig. 1. In addition to the buildings, etc., appearing in this sketch, the company owns and operates a village for its employees, the plant being located in an isolated mountain district of southwestern Virginia.

The coal to be carbonized is dumped from railroad cars into a track hopper, carried on a Link-Belt apron conveyor to a Williams No. 3 hammer mill and crushed to pass a [illegible]-in. bar screen. It is then elevated by a Link-Belt bucket elevator to the top of the primary retort house and distributed by a flight conveyor to steel coal bins supplying the retorts. The capacity of this coal-handling equipment is, roughly, 50 tons per hour.

The primary retorts are of the type described in the first paper of this series.[2] For convenience a sketch of this retort is reproduced as Fig. 2. Twenty-four such retorts are arranged in four batteries, with the feed ends of the retorts turned together so that one coal bin serves four retorts, and a 50-hp. motor drives the feed screws and paddle shafts on twelve retorts. The carbon residue from the "Vesuvius" discharge falls on rubber-covered conveyor belts and is carried to the grinding mills, one belt serving twelve retorts. The scrubber standpipe from each retort carries the foul gas into a common main leading to the byproduct house.

The carbon residue was originally ground in Williams No. 3 hammer mills, two of these being installed underneath the carbon residue storage bins. It was found, however, that the hammers on these mills would last

[1] Article by Brandeger, *The Black Diamond*, July, 1920, describes the plant in some detail.

[2] *Chem. & Met.* vol. 28, No. 1, p. 11, Jan. 3, 1923.

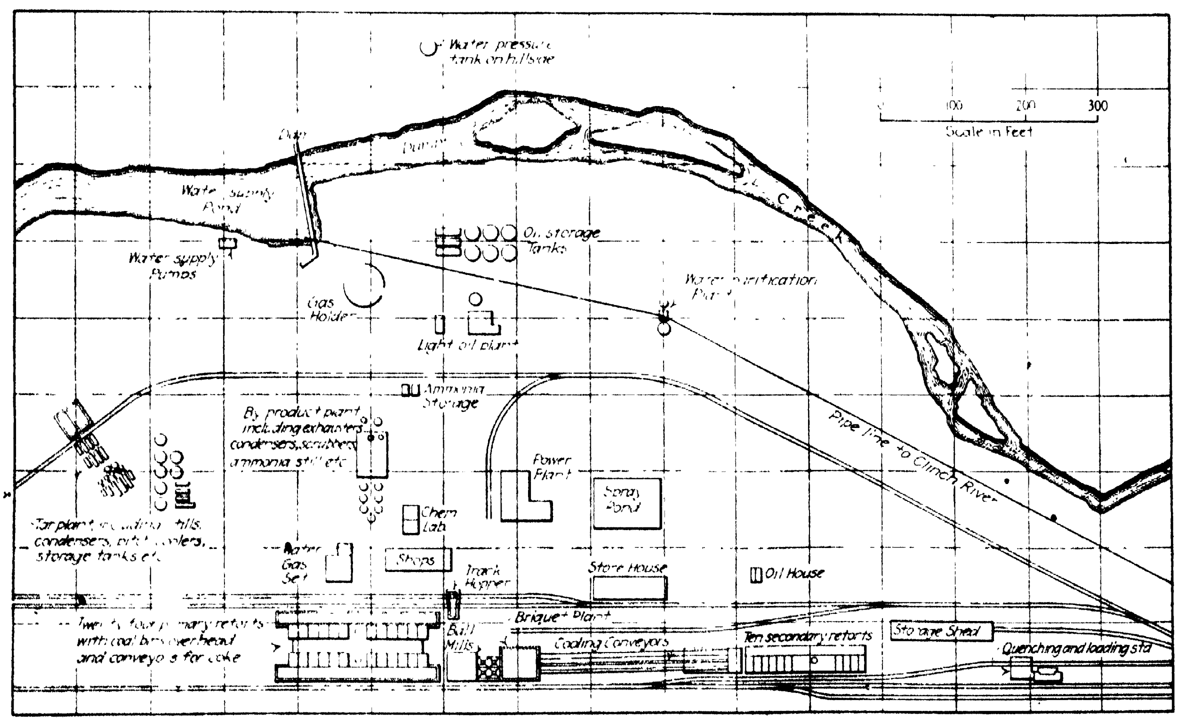

FIG. 1—GENERAL LAYOUT OF CLINCHFIELD CARBOCOAL PLANT

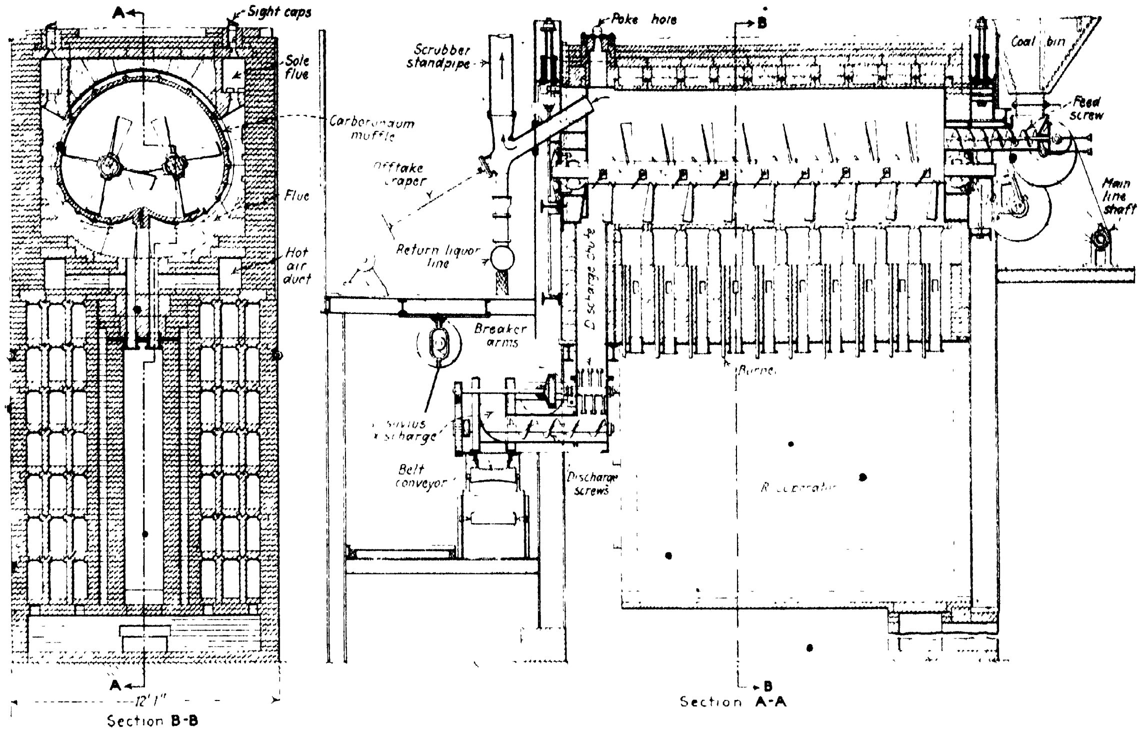

FIG. 2- CLINCHFIELD PRIMARY RETORT

ily about 24 hours. Finally the mills were abandoned nd a ball mill installed ahead of the storage bins. After rinding, the carbon residue is elevated to storage bins; om the bottom of these bins it is fed by a drag-chain roportioning conveyor to a bucket elevator, and deliv-red to a horizontal paddle mixer, where it is mixed ith molten pitch. The paddle mixer empties into a uxer, where the material is stirred and is heated with ve steam. The fluxer empties by gravity into a sec-nd paddle mixer feeding the briquet presses. All of ie grinding, elevating, mixing, fluxing and briquetting quipment is installed in duplicate units, each having apacity sufficient for the whole output of the primary etorts. The briquet presses are of the roll type with at-link chains running between the molds so as to give riquets with flattened ends.

The warm briquets from the presses fall onto long, etallic chain-belt, cooling conveyors and are carried lowly up to a raw briquet storage bin. From the bot-om of this bin the raw briquets are withdrawn over a haker screen into a steel larry car serving the sec-ndary retorts.

There are thirty secondary retorts arranged in ten enches of three retorts each. The retorts are divided nto an upper and lower chamber by a silica brick parti-ion, the chambers opening into each other at either nd Fig. 3 shows the general features of a secondary etort. The retorts are heated by vertical flues between em, with gas burners at the top of the flues. The wer ends of the flues open into a common duct passing p along the floor of the lower retort chamber and lead-ig to the recuperator.

In these secondary retorts the briquets are carbon-ed for 8 to 10 hours, at a temperature which eventually eaches about 1,800 deg. F., the byproducts from this rbonization being collected and handled along with ose from the primary retorts. At the end of the rbonizing period the discharge door at the lower end the retort is opened and the briquets permitted to run out, the charge being poked with rods from the lower end if it hangs in the retort. The red hot briquets are quenched under a water spray, screened and loaded for shipment. In Fig. 4 there is shown a diagrammatic representation of the whole Carbocoal process, indicating the individual units.

The plant includes, besides the usual byproducts equipment, a tar plant, power plant, light oil refinery,

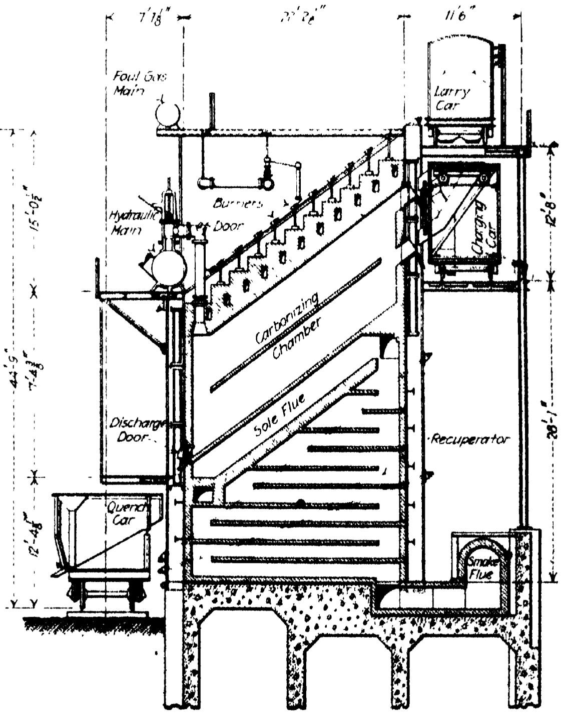

FIG. 3—CLINCHFIELD SECONDARY RETORTS

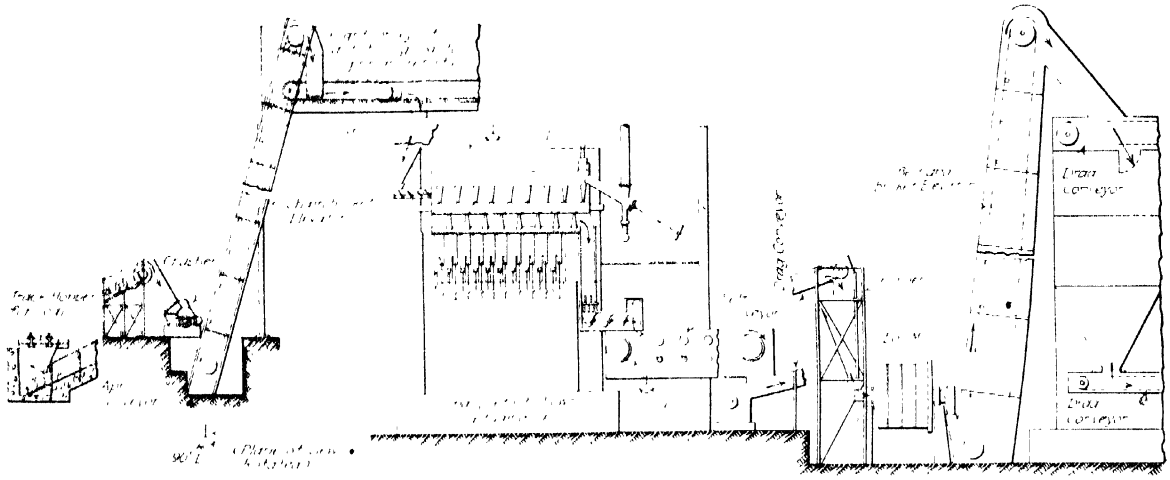

FIG. 1—EQUIPMENT FOR CARBOCOAL PRODUCTION (NOT DRAWN TO SCALE)

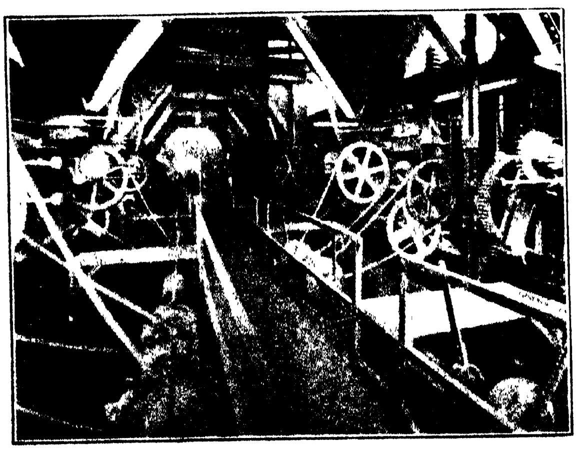
laboratory, shop, storehouses, etc., as shown in Fig. 1. A pair of water gas generators are provided for starting the plant and to make up any deficit in gas supply.

Errors in Plant Design

In deciding upon equipment and layout for the Clinchfield plant there was apparently poor liaison between the officers of the company who approved the designs and the operating crew at the company's Irvington plant. While in general the Clinchfield plant was designed along the lines worked out at Irvington, there were numerous cases where Irvington experience was disregarded and equipment installed which had already been found inadequate. Certain parts of the plant are poorly arranged and there is evidence of poor engineering throughout the plant. It was, of course, inevitable that in a pioneer project of this sort mistakes would be made, but the Clinchfield plant certainly included more blunders than might reasonably be expected. This was most unfortunate, for the operating difficulties connected with a new process were certain to be numerous under the best of planning. As a matter of fact, the difficulties encountered at the Clinchfield plant were so numerous and so persistent that, although the plant was kept operating, the manufacturing costs bore no relation to the actual costs of carrying out the steps of the process, and after nearly 2 years of operation it finally appeared best to shut the plant down temporarily and solve some of the mechanical problems.



PADDLE DRIVES AND FEED MECHANISMS, PRIMARY RETORTS

In the pages which follow a number of operating difficulties are discussed and the method of overcoming some of them given. It should by no means be concluded that the whole Clinchfield plant was a failure mechanically, for such was not the case. The plant was operated and many thousands of tons of Carbocoal sent to market during 1920 and 1921. Commercial operation was deliberately discontinued in March, 1922, because persistent mechanical difficulties ran up the manufacturing costs above the market value of the products. Since March, 1922, an experimental program has been followed actively and solutions have been found for several of the most serious difficulties. It is only a question of solving minor mechanical problems now. The process itself is sound, the fuel produced readily salable, and the remaining mechanical problems are well defined.

Operation Difficulties

Carbon Deposit in Primary Retorts

Referring to Fig. 2, it is noted that there are necessarily small clearances between the ends of the paddles and the retort walls. Shortly after a retort is put into operation this space fills with carbon residue baked in place. At first this layer between the ends of the paddles and the retort wall is soft, but it gradually hardens until it passes the hardness of steel. The paddles then drag heavily over this hard surface, which ever tends to grow thicker until after, say, 50 or 60 or 70 days there comes a time when the resistance offered to the motion of the paddles is great enough to break the paddles, the paddle shafts or some part of the driving train.

At the time the Clinchfield plant was built it was known that this carbon deposit in the retort would give trouble, but it was thought that cleaning the retort once in 5 or 6 months would suffice. It was found in Clinchfield operation, however, that there was danger of breaking something after about 60 days. This was serious. In fact, this was perhaps the most serious problem which developed at Clinchfield. Persistent, foolishly persistent, attempts were made to keep retorts operating longer than 60 days, regardless of breakage with results which were disastrous to the cost data at Clinchfield.

Numerous attempts had been made at Irvington and

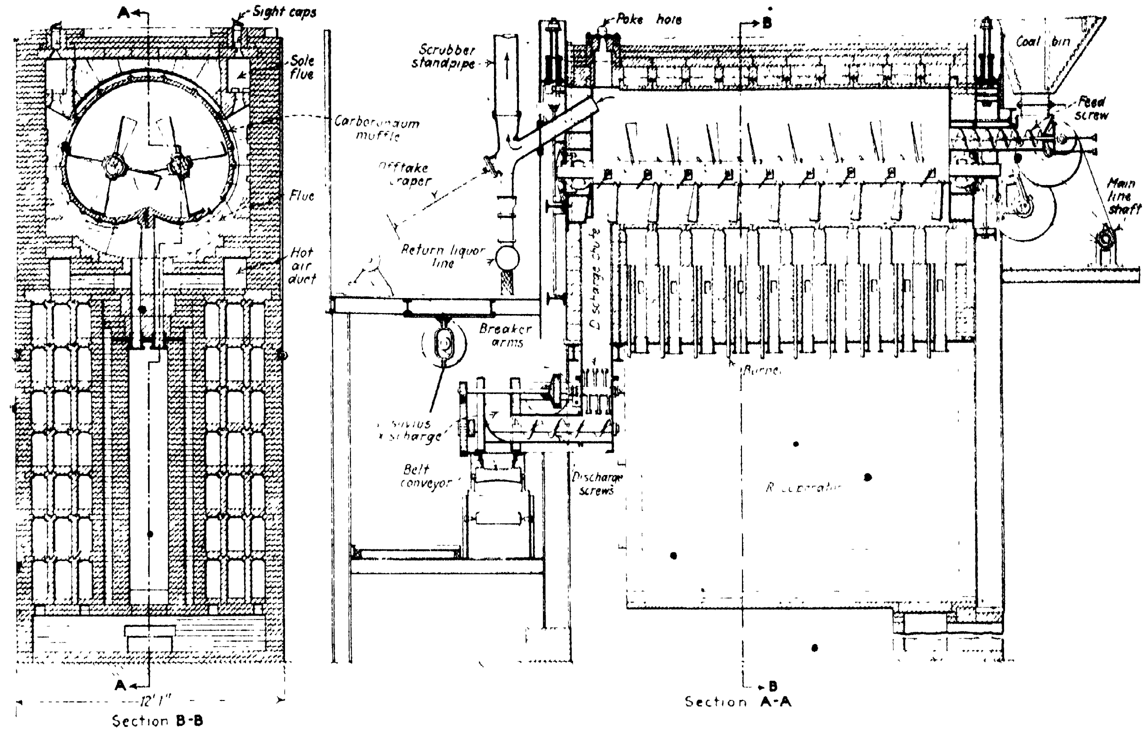


FIG. 2- CLINCHFIELD PRIMARY RETORT

nly about 24 hours. Finally the mills were abandoned nd a ball mill installed ahead of the storage bins. After rinding, the carbon residue is elevated to storage bins; om the bottom of these bins it is fed by a drag-chain roportioning conveyor to a bucket elevator, and deliv- red to a horizontal paddle mixer, where it is mixed ith molten pitch. The paddle mixer empties into a uxer, where the material is stirred and is heated with ve steam. The fluxer empties by gravity into a sec- nd paddle mixer feeding the briquet presses. All of e grinding, elevating, mixing, fluxing and briquetting quipment is installed in duplicate units, each having apacity sufficient for the whole output of the primary etorts. The briquet presses are of the roll type with at-link chains running between the molds so as to give riquets with flattened ends.

The warm briquets from the presses fall onto long, etallic chain-belt, cooling conveyors and are carried lowly up to a raw briquet storage bin. From the bot- om of this bin the raw briquets are withdrawn over a haker screen into a steel larry car serving the sec- ndary retorts.

There are thirty secondary retorts arranged in ten enches of three retorts each. The retorts are divided nto an upper and lower chamber by a silica brick parti- ion, the chambers opening into each other at either nd Fig. 3 shows the general features of a secondary etort. The retorts are heated by vertical flues between hem, with gas burners at the top of the flues. The wer ends of the flues open into a common duct passing p along the floor of the lower retort chamber and lead- ng to the recuperator.

In these secondary retorts the briquets are carbon- ed for 8 to 10 hours, at a temperature which eventually eaches about 1,800 deg. F., the byproducts from this rbonization being collected and handled along with ose from the primary retorts. At the end of the arbonizing period the discharge door at the lower end the retort is opened and the briquets permitted to run out, the charge being poked with rods from the lower end if it hangs in the retort. The red hot briquets are quenched under a water spray, screened and loaded for shipment. In Fig. 4 there is shown a diagrammatic representation of the whole Carbocoal process, indicating the individual units.

The plant includes, besides the usual byproducts equipment, a tar plant, power plant, light oil refinery,

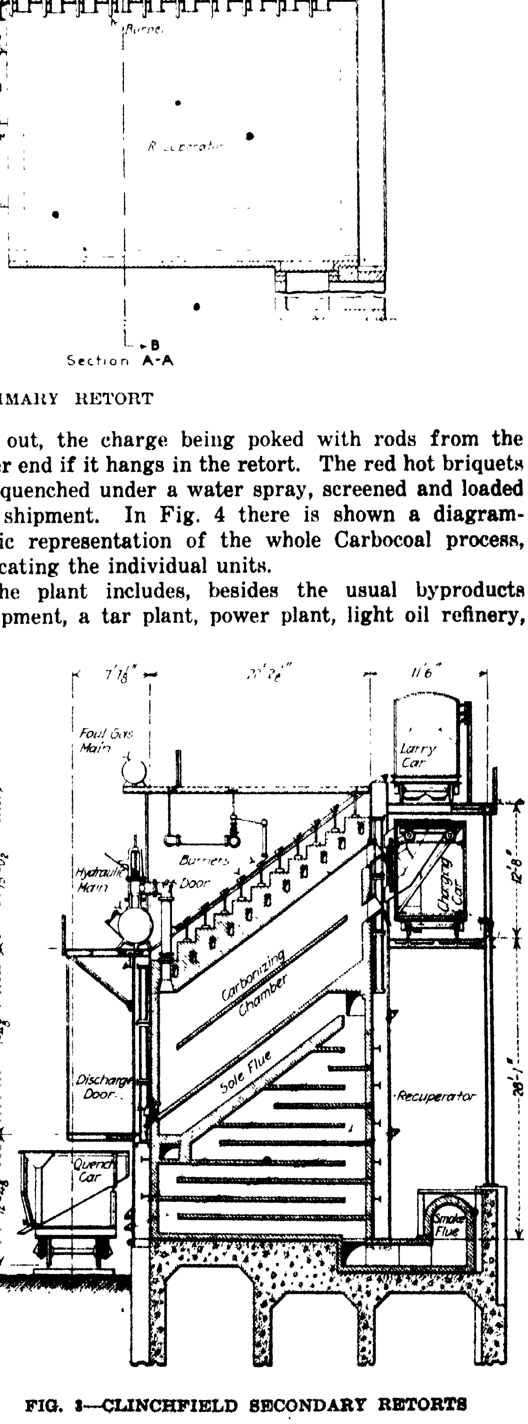

FIG. 3—CLINCHFIELD SECONDARY RETORTS

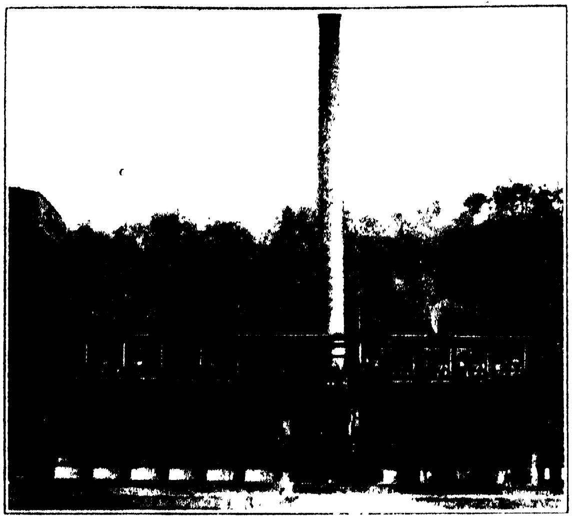

BATTERY OF SECONDARY RETORTS

of hot, carbon dioxide-bearing air into the retort. This carbon dioxide gave trouble later, of course, in the ammonia recovery equipment.

In addition to the above defect, the end-flights on the discharge screws and the driving gears on the discharge mechanism wore out rapidly due to the heavy work of pushing the carbon residue up over the dam in the "Vesuvius." Whenever the carbon residue was discharged in a plastic condition and whenever the end-flight had worn down to a certain point, the discharge would jam. It was then necessary to open relief discharge doors at the foot of the discharge chute while the hot screws were hauled out and the flights renewed.

Altogether, the discharge arrangement on the Clinchfield retort was thoroughly bad. A crew of mechanics was busy continually getting discharges back into operation, with consequent unnecessary increase in the operating costs.

Since the sealing of the retort accomplished by forcing the carbon residue up over the dam in the "Vesuvius" was so slight, it was eventually decided to cut a hole in the bottom of this casting and permit the carbon residue to fall directly from the discharge screws onto the conveyor belts. This relieved much of the load on the discharge drive mechanism and did not materially change the other conditions of operation. The discharges were in use this way at the time the plant was closed down in March, 1922 Since that time experiments with various discharge arrangements have been conducted. A successful discharge has been developed in which the carbon residue falls into an inclined cooling chamber at the end of the retort with a water-sealed door at the bottom of the chamber. From the cooling chambers to the ball mill the carbon residue will be moved in steel cars mounted on a track running around the batteries. Tests on this scheme are now in progress.

The Conveyor System for Carbon Residue

Belt conveyors were installed at Clinchfield for handling the carbon residue from the primary retorts to the ball mills. Experience has shown that the carbon residue coming from the retorts is too hot to be handled by rubber-covered conveyor belts. Replacements were required frequently, but the belts were continued in use.

As an experiment a short drag conveyor was installed just ahead of the ball mill hopper. The abrasive carbon residue caused excessive wear on the chain guides and the equipment would soon have been worn out if it had been continued in service. It is probable that a pan or an apron conveyor would be satisfactory. Our present scheme, however, is to use small hopper cars instead of a conveyor.

The Gas Offtake, Primary Retorts

In Clinchfield operation it was found difficult to keep the gas offtakes clean. As originally built each retort was provided with a hand-operated scraper in the gas offtake. The scraper would stick in the offtake frequently and its operation was irksome. For some time no scraper was used, the offtakes being poked out with a rod when they became so choked as to interfere with retort operation. Later, however, the scrapers were replaced and an electric motor for driving them mounted on an overhead track. This made a fairly satisfactory arrangement. During some recent experiments it was found that a certain arrangement of liquor sprays eliminated most of the gas offtake trouble, and these sprays will eventually be installed on all the retorts.

Grinding Equipment

It has been found at Irvington that the Williams hammer mill was unsuited for grinding material as abrasive as carbon residue. Completely disregarding this experience, two such hammer mills were installed at Clinchfield. As a result, the screen analysis on the ground carbon residue was seldom correct for getting best results, and this accounted in part for the poor quality of the Carbocoal made at first. Five months after the plant was started, a Kennedy-Van Saun ball mill was installed and during the summer of 1921 a Marcy ball mill was added. Either one of these mills will grind the total carbon residue output of the primary retorts, say 18 tons per hour. The Marcy mill is much the superior of the two mills.

While the ball mills grind the carbon residue satisfactorily and stand up well under constant use, we feel that the grinding problem is not entirely solved. The ball mills in use now require 200- to 250-hp. drive motors. The power cost for grinding seems too high. It is possible that much smaller rod mills would do the work satisfactorily, and this experiment is on our schedule.

The Briquet Presses

The briquet presses installed at Clinchfield are roll presses with flat-link chains running between briquet dies so as to give briquets with flat ends. These presses are exceptionally well built, but, unfortunately, the wear on the chains with a material as abrasive as carbon residue is excessive, even though the chains be made of glass-hard alloy steel. When the chains wear thin, they do not fill their grooves on the rolls and briquet material is forced into these grooves, preventing the briquets from slipping in the dies as they pass beyond the point of maximum pressure. This gives briquets with one rough side and increases the percentage of fines beyond the presses. It is likely that some type of Belgian press without the chains will be installed before operations are resumed at Clinchfield.

Handling of Raw Briquets

It was known at Irvington that the raw briquets should be handled gently and that it was bad practice

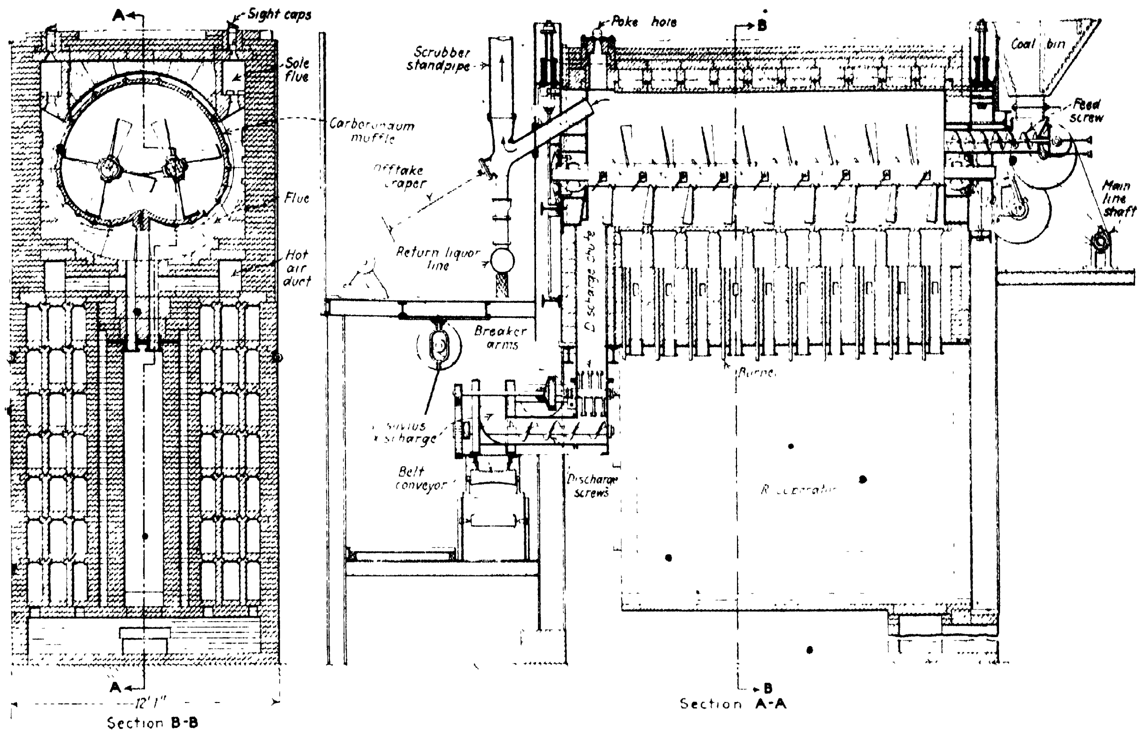

FIG 2- CLINCHFIELD PRIMARY RETORT

nly about 24 hours. Finally the mills were abandoned nd a ball mill installed ahead of the storage bins. After rinding, the carbon residue is elevated to storage bins; rom the bottom of these bins it is fed by a drag-chain roportioning conveyor to a bucket elevator, and deliv- red to a horizontal paddle mixer, where it is mixed ith molten pitch. The paddle mixer empties into a uxer, where the material is stirred and is heated with ve steam. The fluxer empties by gravity into a sec- nd paddle mixer feeding the briquet presses. All of e grinding, elevating, mixing, fluxing and briquetting quipment is installed in duplicate units, each having apacity sufficient for the whole output of the primary etorts. The briquet presses are of the roll type with at-link chains running between the molds so as to give riquets with flattened ends.

The warm briquets from the presses fall onto long, etallic chain-belt, cooling conveyors and are carried lowly up to a raw briquet storage bin. From the bot- om of this bin the raw briquets are withdrawn over a haker screen into a steel larry car serving the sec- ndary retorts.

There are thirty secondary retorts arranged in ten enches of three retorts each. The retorts are divided nto an upper and lower chamber by a silica brick parti- ion, the chambers opening into each other at either nd Fig. 3 shows the general features of a secondary etort. The retorts are heated by vertical flues between hem, with gas burners at the top of the flues. The wer ends of the flues open into a common duct passing p along the floor of the lower retort chamber and lead- ng to the recuperator.

In these secondary retorts the briquets are carbon- ed for 8 to 10 hours, at a temperature which eventually eaches about 1,800 deg. F., the byproducts from this rbonization being collected and handled along with ose from the primary retorts. At the end of the rbonizing period the discharge door at the lower end the retort is opened and the briquets permitted to run out, the charge being poked with rods from the lower end if it hangs in the retort. The red hot briquets are quenched under a water spray, screened and loaded for shipment. In Fig. 4 there is shown a diagrammatic representation of the whole Carbocoal process, indicating the individual units.

The plant includes, besides the usual byproducts equipment, a tar plant, power plant, light oil refinery,

Legal Notes

By Wellington Gustin

Perkins Patent for Process and Product Covering Glue Upheld in Three Cases

The Perkins reissue patent, No. 13,434, for a wood glue and process of making same was held valid and infringed in the cases of Perkins Glue Co. vs. Hood & Wright and same vs. the West Michigan Furniture Co., 279 Fed. Rep., 454, decided by District Judge Sessions.

Suit was brought in each case for infringement of two process claims, Nos. 13 and 38, and three product claims, Nos. 28, 30 and 31, of the patent. The patent covers a vegetable glue derived from starch or starchy products, having the adhesive strength and qualities of animal glue and suitable for gluing woods, especially veneers; and also the method or process of making such glue.

Glue Base Purchased and Treated by Method of Patent

The defendants used the glue mainly for making veneers. Each bought the prepared glue base from the National Process Co., then subjected the glue base so purchased to the treatment of the final process described in the patent, and thus produces the glue of the patent ready for use.

The glue base manufactured and sold by the National and International Process companies of Indianapolis and used by the defendants is not prepared in accordance with the method or first step of the process of the patent, but is produced by mixing commercial starches of different grades and kinds, the raw, underdegenerated and overdegenerated starches being so proportioned that the mixture has the same average degeneration and the same water absorptive properties as the processed glue base of the patent.

Claims for Final Process and Resultant Product Valid

The court found the claims of the patent for the glue base as well as the process of preparing it to be invalid, but same were not involved in this action. But it did find that the claims for the finished product and for the complete process of preparing such product were valid; also it found that the claims for the glue resulting from the application of the final process to the glue base of the patent are valid, notwithstanding the fact that neither the glue base itself nor the process of making it is patentable.

For the glue base may be produced, it was admitted, without using the inventor's preferred process. And it follows, said the court, that the claims for the inventor's final process, applied to or in combination with the glue base of the patent, in whatever manner such base may have been produced, are valid. A patentable product does not result from the practice of an old, well-known and non-patentable process. The Court of Appeals had, in a former case, held the claims valid for the final process and the resultant product. Clearly, it says here, "final" process does not necessarily or presumably mean "complete" process and the patent claims were "not strictly for the second step of the process above and as such, but are for the final process, applied to or in combination with the glue base of the patent."

Now the owner of a patent is bound by the disclaimer in the patent. The sole object of the disclaimer in the patent at bar was to narrow the claims with respect to the starchy product or glue base to be subjected to the final process of the patent. Under the disclaimer the starch or starchy product to be processed must be degenerated to the extent described in the patent before being subjected to the final process of the patent. So limited, the claims are valid and infringed, said the court.

Case Where Single Starch Was Used for Base

This same court was called to pass upon the patent again in an action brought against the Holland Furniture Co. and others.

The only substantial difference between the former cases and this one was found in the method of producing a part of the base used by the defendants in the production of the glue. In this case a part of the glue base was produced by another manufacturer by selecting a single grade and quality of commercial cassava starch and merely sifting out the impurities therein contained. Manifestly the resultant glue base is the same, whether consisting of a mixture of starches of different degrees of degeneration or of a single starch of the same degree of degeneration as the mixture. Defendant's final product was obtained by subjecting the glue base to the treatment described in the patent as the second or final step of the patented process, and was identical with the glue of the patent; and the court held it did so combine product and process in the preparation of its glue as to infringe the product claims of the patent.

Standard of Comparison for Determining Profit From Infringement of Alkaline Process for Reclaiming Rubber

The standard of comparison for determining profits earned by an infringement is a point involved in a suit brought by the Philadelphia Rubber Works against the United States Rubber Reclaiming Works and others. There it was held by the Circuit Court of Appeals of the United States that a process developed by an infringer after an injunction against infringement was issued to avoid the infringement, cannot be adopted as a standard of comparison in determining the profits due to the infringement. (277 Federal, 171.)

The case was before the Court of Appeals from a decree by the District Court fixing the amount of damages for the infringement after an accounting, both sides appealing. Plaintiff had been awarded the sum of $324,597.46 as profits which were realized by the defendants during a period of 5 years of alleged infringement of plaintiff's patent. Plaintiff appealed for the reason that it contended the award was too small.

The suit involves the Marks patent, No. 635,141, owned by the plaintiff, Philadelphia Rubber Works, covering a process for devulcanizing rubber waste. The patent was held valid and infringed in the District Court, and this result was affirmed on appeal. (143 C. C. A., 426.) There the court decided that the Marks patent accomplished a new result by the application of a new process to the reclamation of rubber waste. Defendant, United States Rubber Reclaiming Works, conveyed its business and property to the United States Rubber Reclaiming Co., Inc., which later transferred its assets and business to the Madison Tire & Rubber Co., each of which were made parties defendants in this suit.

The District Court ruled that there was no standard of comparison from which to estimate the profits, and that the plaintiff was entitled to recover the entire profits made by the defendants from reclaimed rubber produced by the infringing process. It refused to allow a deduction of $179,309.24 for alleged profits on the compounds which the defendants claim that they incorporated into the reclaimed rubber sold. It further refused to allow the defendants a reduction of $75,-946.24 for alleged profits made from operations subsequent to the devulcanizing process, which operations are usual and customary in reclaiming rubber to put the product in condition for sale. To the sum agreed upon by the accountants as the basic figure of profits, $610,581.66, the court added $10,982.48, a portion of $21,507.30 which was deducted in fixing said sum as special expenses, a proportion of the sum of $21,004.18 legal expenses, and a proportion of the reorganization expenses of defendants of $3,461.71. The court held this to have been improperly charged to the cost of the operation with the infringing process.

District Court Allowed Recovery of Entire Profits

Further, the District Court reduced the profits by $122,932.57, apportioning certain expenses between the infringing and non-infringing processes—that is, it divided the general expenses equally between the defendants' two mills and allowed this as a deduction. The plaintiff claims that the court should have followed the method adopted by the accountants jointly representing the parties. Then the court allowed a reduction of $197,200.72 for interest on capital invested in the plant and business using the infringing process. Defendants claimed the court erred in making the Madison Tire & Rubber Co. a party and requiring payment of the damages by it.

Marks Process

The process of the Marks patent for devulcanizing rubber waste consists in submerging the finely ground rubber waste in a dilute alkaline solution in a sealed vessel, and in keeping the contents of the vessel at a temperature of 3.4 deg. F., and in maintaining this temperature for 20 hours, more or less. The court held that the defendants appropriated the essential elements of this process and thereby achieved the same result as the Marks patent accomplishes. The questions of validity and infringement were established against the ...nts by the previous decision of the court cited above.

The Marks process opened a new field for production of reclaimed rubber—that being from highly vulcanized scrap. This had never previously been successfully accomplished. By the acid process, the court found, rubber had been reclaimed from boots and shoes and made capable of being used for other purposes. But from the reception and use of the Marks process in the trade and the results accomplished by it, the court found this process was of great monetary and economic value, particularly in reclaiming rubber used in automobile tires.

Alkaline Process Only One Successful With Tire Scrap

It is pointed out that the devulcanized rubber must not only possess a maximum plasticity and absorptive ability but must not lose these properties with age, and the revulcanized reclaimed rubber must show high tensile strength and high elongation, and must retain these properties for a maximum period of time. Tire scrap devulcanized by the acid process does not exhibit these properties, which are observed in the stock devulcanized by the alkali process. And also because of its increased plasticity prior to vulcanization, the alkali stock exhibits a superior abrasive resistance, and is superior as to aging. Such that proof showed that the Marks patent was one of the most successful and valuable rubber patents ever issued.

It was found that the defendants' product essentially derived its marketability and value from the unlawful appropriation of the process of Marks. Therefore the court awarded the plaintiff, owner of the Marks patent, the entire profits made by defendants from the sale of reclaimed rubber produced by the Marks process.

The Court of Appeals held that the rule of damages applied by the court below was correct, and that there was no process in use or known which could be used as a standard of comparison as contended for by the defendants. Again, it says that in determining the profits of an infringer, other methods of accomplishing the results of the patented process cannot be used as standards of comparison, if such methods were covered by other patents so as not to be available to the infringer.

No Other Method Available for Defendants

In such cases, the court says, in finding the proper amount of damages the question to be determined is, What advantage did the defendant derive from using the plaintiff's invention over what he had in using other processes then open to the public and adequate to obtain an equally beneficial result? The fruits of that advantage are the profits, and these are the damages to the owner of the invention.

The standard of comparison for determining the profits earned by an infringement, to be applicable in the case, must have been known and open prior to the date of the plaintiff's patent. The field of selection of process which might be used should be, in principle, that which is open to the art at the time the invention is appropriated. Where there is a patent which forbids such use, the question is presented whether it is actually available to the infringer during the period of infringement. Where the owner of the patent declines to permit its use or grant a license, it cannot be set up as a standard of comparison, says the court.

Neither may processes which were developed after the infringement as a substitute for use by the defendants be used as a standard of comparison. In this case the court found no process which might be used as this standard. Therefore the rule applicable required the defendants to pay over to the plaintiff all the profits which they derived through unlawful infringement.

Now, where profits are made by the use of an article patented as an entirety, the infringer is liable for all the profits, unless he can show, and the burden is on him to show, that a portion of them is the result of some other things used.

Claim of Profit on Other Steps Not Allowed

The defendants argued that a small portion only of the total profits is due to the devulcanizing step and that the remainder is due to the finishing and refining steps performed subsequently. The devulcanized rubber is not immediately in condition for sale or use, but is subjected to the refining and finishing steps. Defendants argued that of the total cost of producing

reclaimed rubber, only 18 per cent of that cost is incurred in the devulcanizing step, the balance being due to subsequent steps. But the evidence showed that the value of the product is due to the devulcanizing process, the reclaimed rubber being given characteristics wholly different from the characteristics of acid reclaimed tire scrap. These characteristics result in a new product, which could be attained only by depolymerizing the waste or breaking down the rubber molecules formed during vulcanization. The particular rubber product obtained could be obtained only by the Marks process. The fact is, says the court, that defendants could not have sold the reclaimed rubber without first having imparted to that rubber the characteristics resulting from the Marks process. This cannot be separated from the finishing and refining which help to make the article marketable. The court found it impossible for the defendants, without the wrongful use of plaintiff's process, to carry on their operations as they did. It appeared that the entire commercial value of the rubber arises from the use of the patented process and the court said plaintiff was entitled to recover from the infringer the total profits derived.

Infringer Could Not Claim That Part of Profits Was Made on Compounds

Further, the defendants contended for alleged profits on compounds which were incorporated in the reclaimed rubber sold. There were about 7 per cent of various compounding ingredients used, costing defendants $57,157.72, and they claimed the right to deduct the profits which they claim to have made in these ingredients, or a total sum of $179,309.24. The court found no proof that these compounds, after being combined with the rubber, were of any greater value than when put in. But since the whole product was sold at the market price for rubber, the infringer could not claim that a portion of his profits was a profit on the compounds used, and he is entitled to deduct only the cost of the compounds according to the ruling of the court.

Again, in determining the profits earned by an infringer, special payments made by the infringer to its officers, in addition to their regular salaries, legal expenses incurred in defending the infringement suit and expenses of reorganizing the infringing corporation cannot be deducted from the gross profits. Yet interest on the capital invested in the infringing portion of defendant's business was properly allowed as a charge against the gross profits from the infringing product.

In its findings the court says this was not a willful and deliberate infringement. The District Court was upheld in its holdings by the appellate court, and the United States Supreme Court, after a hearing on a petition for a certiorari to bring it up to that court, denied the petition.

A Slide Rule for Oil Viscosities

For more than 30 years the oil industry has employed various viscosimeters, there being in common use four types—the Saybolt in the United States, the Redwood in England and the colonies, the Engler in Germany and most other countries, including France, where also the Barbey ixometer is used by the French Government.

Unfortunately all attempts to introduce or adopt one type of instrument to be used universally have failed. The scientific method for determining viscosities of oil in absolute measure as poise has not reached the stage to be adopted by the oil industry.

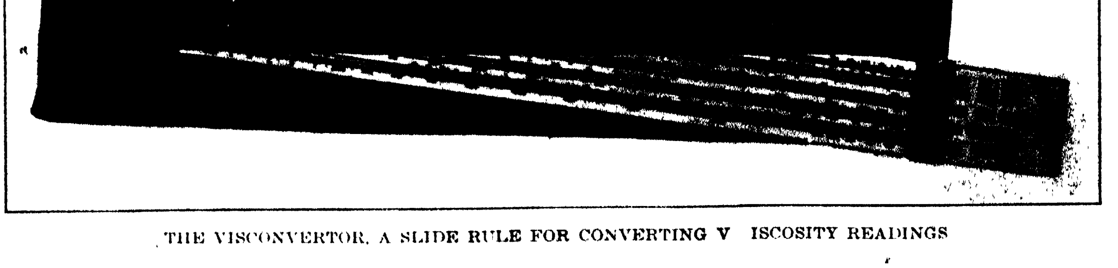
Almost every refinery and plant doing business in foreign countries is handicapped by the requirement of tests on the different instruments as before noted. This means that the actual tests must be made on the various instruments or use made of various calculated tables and plotted curves for the approximate conversion of the viscosity from one instrument to another, which is time consuming and not always accurate.

An attempt to provide the oil industry with an instrument for converting the viscosity of an oil from the value of one instrument to the value of another instrument at the same temperature, as well as at slightly different temperatures, has resulted in the designing of an instrument known as the "Visconvertor" by V. L. Chechot of the physical testing staff of the Atlantic Refining Co. of Philadelphia. Results obtained on this instrument are accurate within a reasonable degree, slight variations being expected in converting from one temperature to another according to the crude source.

The corresponding viscosities are arranged in logarithmical lines, similar to a slide rule, and the reading is made in simple manner by placing a slider over the observed instrument line and reading the corresponding value on the desired instrument line.

The arrangement of the logarithmical lines is such that it is possible to convert viscosities at the same temperature on the four instruments mentioned—viz., Saybolt, Redwood, Engler and Barbey. Also Saybolt at 100 deg. F. can be translated into Engler at 50 deg. C. or Barbey at 50 deg. C.; Saybolt at 100 deg. F. to Redwood at 140 deg. F. or Saybolt at 130 deg. F.; Saybolt at 130 deg. F. to Redwood at 140 deg. F.; Engler at 50 deg. C. to Engler at 20 deg. C. or Barbey at 50 deg. C.; Saybolt at 210 deg. F. to Engler or Barbey; Redwood at 200 deg. F. to Saybolt at 210 deg. F., etc.

The data used in preparing this instrument have been calculated theoretically by means of absolute and kinematic viscosities and then verified by actual tests on certified instruments. The reverse side of the rule contains a considerable amount of data and formulas pertaining to the oil industry.



THE VISCONVERTOR, A SLIDE RULE FOR CONVERTING VISCOSITY READINGS

The District Court ruled that there was no standard of comparison from which to estimate the profits, and that the plaintiff was entitled to recover the entire profits made by the defendants from reclaimed rubber produced by the infringing process. It refused to allow a deduction of $179,309.24 for alleged profits on the compounds which the defendants claim that they incorporated into the reclaimed rubber sold. It further refused to allow the defendants a reduction of $75,946.24 for alleged profits made from operations subsequent to the devulcanizing process, which operations are usual and customary in reclaiming rubber to put the product in condition for sale. To the sum agreed upon by the accountants as the basic figure of profits, $610,581.66, the court added $10,982.48, a portion of $21,507.30 which was deducted in fixing said sum as special expenses, a proportion of the sum of $21,004.18 legal expenses, and a proportion of the reorganization expenses of defendants of $3,461.71. The court held this to have been improperly charged to the cost of the operation with the infringing process.

District Court Allowed Recovery of Entire Profits

Further, the District Court reduced the profits by $122,932.57, apportioning certain expenses between the infringing and non-infringing processes—that is, it divided the general expenses equally between the defendants' two mills and allowed this as a deduction. The plaintiff claims that the court should have followed the method adopted by the accountants jointly representing the parties. Then the court allowed a reduction of $197,200.72 for interest on capital invested in the plant and business using the infringing process. Defendants claimed the court erred in making the Madison Tire & Rubber Co. a party and requiring payment of the damages by it.

Marks Process

The process of the Marks patent for devulcanizing rubber waste consists in submerging the finely ground rubber waste in a dilute alkaline solution in a sealed vessel, and in keeping the contents of the vessel at a temperature of 344 deg. F., and in maintaining this temperature for 20 hours, more or less. The court held that the defendants appropriated the essential elements of this process and thereby achieved the same result as the Marks patent accomplishes. The questions of validity and infringement were established against the ...nts by the previous decision of the court cited above.

The Marks process opened a new field for production of reclaimed rubber—that being from highly vulcanized scrap. This had never previously been successfully accomplished. By the acid process, the court found, rubber had been reclaimed from boots and shoes and made capable of being used for other purposes. But from the reception and use of the Marks process in the trade and the results accomplished by it, the court found this process was of great monetary and economic value, particularly in reclaiming rubber used in automobile tires.

Alkaline Process Only One Successful With Tire Scrap

It is pointed out that the devulcanized rubber must not only possess a maximum plasticity and absorptive ability but must not lose these properties with age, and the revulcanized reclaimed rubber must show high tensile strength and high elongation, and must retain these properties for a maximum period of time. Tire scrap devulcanized by the acid process does not exhibit these properties, which are observed in the stock devulcanized by the alkali process. And also because of its increased plasticity prior to vulcanization, the alkali stock exhibits a superior abrasive resistance, and is superior as to aging. Such that proof showed that the Marks patent was one of the most successful and valuable rubber patents ever issued.

It was found that the defendants' product essentially derived its marketability and value from the unlawful appropriation of the process of Marks. Therefore the court awarded the plaintiff, owner of the Marks patent, the entire profits made by defendants from the sale of reclaimed rubber produced by the Marks process.

The Court of Appeals held that the rule of damages applied by the court below was correct, and that there was no process in use or known which could be used as a standard of comparison as contended for by the defendants. Again, it says that in determining the profits of an infringer, other methods of accomplishing the results of the patented process cannot be used as standards of comparison, if such methods were covered by other patents so as not to be available to the infringer.

No Other Method Available for Defendants

In such cases, the court says, in finding the proper amount of damages the question to be determined is, What advantage did the defendant derive from using the plaintiff's invention over what he had in using other processes then open to the public and adequate to obtain an equally beneficial result? The fruits of that advantage are the profits, and these are the damages to the owner of the invention.

The standard of comparison for determining the profits earned by an infringement, to be applicable in the case, must have been known and open prior to the date of the plaintiff's patent. The field of selection of process which might be used should be, in principle, that which is open to the art at the time the invention is appropriated. Where there is a patent which forbids such use, the question is presented whether it is actually available to the infringer during the period of infringement. Where the owner of the patent declines to permit its use or grant a license, it cannot be set up as a standard of comparison, says the court.

Neither may processes which were developed after the infringement as a substitute for use by the defendants be used as a standard of comparison. In this case the court found no process which might be used as this standard. Therefore the rule applicable required the defendants to pay over to the plaintiff all the profits which they derived through unlawful infringement.

Now, where profits are made by the use of an article patented as an entirety, the infringer is liable for all the profits, unless he can show, and the burden is on him to show, that a portion of them is the result of some other things used.

Claim of Profit on Other Steps Not Allowed

The defendants argued that a small portion only of the total profits is due to the devulcanizing step and that the remainder is due to the finishing and refining steps performed subsequently. The devulcanized rubber is not immediately in condition for sale or use, but is subjected to the refining and finishing steps. Defendants argued that of the total cost of producing

Cellulose Acetate Solvent—The use of cyclobutanone as solvent for cellulose acetates in the manufacture of varnishes, artificial silk and films is covered by a patent granted to Henry Dreyfus. It is claimed that cyclobutanone is an excellent solvent for cellulose acetate, better than cyclohexanone. The cyclobutanone or side chain homologues thereof may be used in any desired quantity relative to the cellulose acetate either alone or with suitable diluents or solvents, such as methyl alcohol, acetone, etc. Any other usual or suitable substances such as camphor, fillers, coloring matter, etc., may be added in making the various products. (1,440,006. Henry Dreyfus, London, England. Dec. 26, 1922.)

Ammonia as Nitrocellulose Solvent—A patent recently issued to John Collins Clancy covers the use of liquid anhydrous ammonia as a solvent for nitrocellulose. Anhydrous ammonia is said to serve as an excellent solvent for the nitrates of cellulose generally, being capable of readily dissolving the higher nitrates which have heretofore been regarded as insoluble or soluble only in a very limited number of solvents. It is also claimed that the higher nitrates, as well as the more readily soluble lower nitrates, can be dissolved in liquid anhydrous ammonia without losing their structural aggregates.

Not only is it possible to dissolve the nitrates of cellulose in liquid anhydrous ammonia, but solutions thus formed may be transferred into other suitable menstrua and upon evaporating off the ammonia the nitrates will remain in solution in the menstrua to which they have been transferred, even though the nitrates were not initially soluble in such menstrua.

It is claimed that the same result may be accomplished by simply moistening the cellulose nitrates with liquid anhydrous ammonia, thereby changing the nitrates to a gelatinous mass, even when the ammonia is not added in sufficient quantity to form a clear solution. The cellulose nitrates thus treated when transferred to the tetrachlorethane, carbon tetrachloride, benzene, alcohol or ester, which is to constitute the final solution medium, will immediately form a clear transparent solution of any degree of viscosity desired, and when the process is carried out by this method the use of pressure may be dispensed with, as a sufficient quantity of ammonia will remain in the cellulose nitrates during the transfer to the solvent, even at atmospheric pressure, to render the nitrates soluble in the second solvent.

The advantages of such a process are pointed out in the specifications. Obviously, this extra step in the solution of nitrates of cellulose will allow a wider latitude in the choice of solvent for a nitrocellulose solution of any desired characteristics. It also would permit the use of non-flammable solvents which cannot be used ordinarily on account of their low solvent value. (1,439,293. John Collins Clancy, Providence, R. I.; assignor to the Nitrogen Corp. of Providence. Dec. 19, 1922.)

Cellulose Nitrate — The cellulose nitrate used in the manufacture of pyroxylin plastics is usually made by nitrating shredded tissue paper. It is a well known fact that during the nitration process there is a considerable amount of acid lost by chemical combination with the cellulose and by the formation of acid fumes and by the mechanical retention of acid in the nitrated fiber. R. P. Calvert has been granted a patent which is assigned to E. I. du Pont de Nemours & Co., Wilmington, Del., covering the process of compressing the paper before it is nitrated by passing it through calenders under a pressure sufficient to materially reduce its thickness. The results of experiments made to compare the acid loss on paper which was nitrated without previous compression with that which had been subjected to the extra step showed a net saving of about 0.4 of a pound of concentrated acid for each pound of nitrocellulose produced. (1,437,041. Robert P. Calvert, assignor to E. I. du Pont de Nemours & Co. Nov. 28, 1922.)

Reclaiming Nitrocellulose From Pyro Smokeless Powder—At the end of the war there existed large surplus stocks of pyro smokeless powder, originally containing about 0.5 per cent of diphenylamine. Some of this powder is not suitable for use in the arts because the powder grains are difficultly soluble in the usual pyroxylin solvents on account of their relatively large size and also because a solution of pyro has a viscosity which is too high for use in coating fabrics, etc. As is well known the decomposition products of the powder form dark colored nitroso and nitro derivatives, which react with the diphenylamine and make the powder solutions unsuitable for use except in very dark colored products. It has also been found that the presence of diphenylamine in a solution of pyroxylin causes a rapid falling in the viscosity of the solution on standing, just as a number of inorganic salts are known to do. This also militates against the use of pyro powder as a substitute for pure pyroxylin in its various applications.

A patent has been granted to Richard G. Woodbridge, assignor to E. I. du Pont de Nemours & Co., of Wilmington, Del., covering a process for the extraction of diphenylamine from pyro powder. The process comprises immersing the powder grains in a liquid which is substantially a non-solvent for the powder, such as propyl alcohol, butyl alcohol or benzene and heating the mass at a temperature near the boiling point of the solvent. It is preferable to use a liquid which is a non-solvent for the powder, but which, at a boiling temperature, is a good solvent for diphenylamine and is also a solvent for the nitroso and nitro derivatives of diphenylamine.

It is claimed that by such a treatment the viscosity of the powder solution is reduced to a point where it can be conveniently handled and that the diphenylamine content is reduced to a point where its influence is negligible. In an example of the process the patentee describes an experiment in which a sample of powder originally containing 0.45 per cent of diphenylamine was heat treated by immersing in denatured ethyl alcohol containing ½ gal. of benzene to 100 gal. of ethyl alcohol, the alcohol being boiled in a suitable still provided with a reflux condenser. The viscosity of the powder was originally 250 sec. by the so-called steel ball method, in a solvent mixture composed of benzene 50, ethyl alcohol 20, and ethyl acetate 30 parts at a temperature of 28 deg. C. After heating the powder in boiling ethyl alcohol for about 75 hours, using sufficient alcohol to keep the powder covered, the viscosity of the powder was reduced to 20 sec. and the content of the diphenylamine both converted and unconverted remaining in the powder was less than 0.02 per cent, a practically negligible amount.

The relative efficiency of various solvents for accomplishing the two objects of the treatment, namely the lowering of the viscosity of the resulting solution and the extraction of the objectionable diphenylamine are given in the patent disclosure. A modification involving the use of heating under pressure in an autoclave is also covered by the patent. (1,439,656. Dec. 19, 1922.)

Vulcanization of Rubber—Eloi Ricard, of France, has assigned to the Société Ricard, Allenet & Cie. the following patent for the vulcanization of rubber. Many accelerators, such as dimethylaniline, piperidine, anthraquinone, etc., are well known. This invention has to do with the use of furfuramide as an accelerator. From 0.5 to 2 per cent of the weight of the rubber will diminish the vulcanizing time 70 to 80 per cent and the temperature of the heating from 8 to 10 deg. C. (1,440,176. Dec. 26, 1922.)

Production of Alkali-Metal Cyanides—Present production following such processes as U. S. Pat. 1,322,195 yields a product containing 30 per cent of alkali-metal cyanide, the remainder consisting of alkali-metal carbonate and oxide, carbon, iron and sulphur. Other patents show how hydrocyanic acid may be prepared from these crude cyanides, and this is then liquefied, etc. The wide use of pure alkali-metal cyanides, however, has made it desirable to work out a method for the production of pure products from the crude material described above. The present invention has its foundation in the discovery that the reaction which is depended upon to free hydrocyanic acid from the furnace product may be reversed under suitable conditions, which are properly controlled. The hydrocyanic acid reacts with the carbonate of an alkali metal if the mass is held at a temperature of 200 to 500 deg. C. The process further deals with a new method for liberating hydrocyanic acid from the crude mass, consisting in subjecting it to a high concentration of carbon dioxide at comparatively high temperature. The carbon dioxide replaces the cyanide in the furnace mass and the hydrocyanic acid gas mixed with carbon dioxide comes off. This is then absorbed

at from 200 to 500 deg. as mentioned above in suitable converters, the carbon dioxide being returned to the process to liberate more hydrocyanic acid from another batch. (1,439,909. F. J. Metzger, assignor to the Air Reduction Co. of New York. Dec. 26, 1922.)

Purification of Hydrofluoric Acid—Henry Howard has assigned to the Grasselli Chemical Co. a process for the purification of hydrofluoric acid. It consists of bubbling the gases evolved by the action of sulphuric acid on fluorspar through a tower containing potassium sulphate solution. The silicon fluoride or hydrofluosilicic acid, which is the principal impurity, is washed out and the hydrofluoric acid is passed on. The tower must be kept hot enough so that no perceptible condensation takes place. By so operating the tower as to remove some of the solution after each run, the process can be made continuous. The product of the tower is potassium fluosilicate, which may be regarded as a final product or may be distilled again with sulphuric acid, producing hydrofluosilicic acid and potassium sulphate, which latter is then used over again in the absorption of hydrofluosilicic acid. The advantage of this process lies in the fact that a relatively poor grade of spar can be used in generating the hydrofluoric acid. In fact, gravelspar containing as much as 8 per cent silicic acid may be used to produce pure hydrofluoric acid. (1,439,960. Dec. 26, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Synthetic Thymol — 1-methyl-4-isopropyl-3-hydroxybenzene and an isomer thereof are prepared by treating metacresol-sulphonic acid with isopropyl alcohol and concentrated sulphuric acid or with isopropyl hydrogen sulphate at a raised temperature, and subsequently splitting off the sulphonic group. Examples are given showing the treatment in each case, and the sulphonic group is split off by distillation in steam, the oil obtained being freed from isopropylether compounds -for example, by treatment with caustic soda—and the product fractionally distilled. From the after-runnings a product is obtained by crystallization from benzene representing a thymol-isomer, having a melting point 114 to 115 deg. C. The thymol itself may be recrystallized from ligroin. (Br. Pat. 186,202. J. Y. Johnson, London, assignor to Badische Anilin und Soda Fabrik. Nov. 155, 1922.)

Phosphate Fertilizers — Phosphoric compounds suitable for fertilizer, such as naturally occurring phosphates, bone meal and phosphoric slags, are converted into a form soluble in citric acid and partly soluble in citrates by intimate grinding with about one to one and a half parts of a suitable salt of the alkali or alkaline-earth metals, ammonium or magnesium. Double salts of the alkali metals and magnesium may also be used. The sulphates, chlorides, silicates and nitrates of these metals are mentioned as suitable salts, and either the artificially prepared compounds or the naturally occurring varieties such as kainite, schoenite, kieserite and carnallite may be employed. The process is stated to be of particular value in the treatment of Florida phosphates. (Br. Pat. 186,223. R. W. James, London, and Eisenwerk Ges. Maximilianshütte, Rosenberg. Nov. 15, 1922.)

Chlorinating Methane—In the chlorination of methane, steam is employed as a diluent to the reacting gases to moderate the violence of the reaction and at the same time to supply if necessary the heat for its initiation. In general 2 to 5 volumes of steam per unit volume of chlorine are used and temperatures above 650 deg. C. are avoided owing to the decomposition of steam and formation of oxide of carbon. Catalysts such as chlorides of copper, iron, and the alkaline earth metals may be employed, with or without porous carriers. The relative proportions of the reacting gases are dependent on the dimensions of the reaction tubes and upon the products required. Examples are given in which formation respectively of methyl chloride, methylene dichloride, chloroform and of carbon tetrachloride is promoted. (Br. Pat. 186,270. Holzverkohlungs-Industrie Akt.-Ges. and K. Róka, Baden. Nov. 15, 1922.)

Emulsions—Permanent emulsions of the kind in which the internal and external phases are constituted by aqueous liquid and oleaginous material respectively are formed from oleaginous materials which themselves possess water dispersing properties. These properties are acquired by heating or polymerizing the oleaginous materials without oxidizing them, or by heating or polymerizing after or with simultaneous oxidation, whereby the oleaginous material becomes gelatinated, sticky and elastic, such processes being generally known. This treated material may be directly emulsified with the aqueous liquid, or it may be diluted with a quantity of untreated material. The mixture, which also possesses water-dispersing properties, may be subsequently emulsified. The aqueous liquid may contain a little solid matter of a sticky nature—for example, glue or casein—and is added to the oleaginous material during vigorous stirring thereof. The resulting emulsion is soluble in oil and is particularly useful in painting and priming materials as described in specification 175,764, or in the manufacture of margarine or edible fats as described in specification 178,885. In an example 100 parts of refined soya oil are agitated at 250 deg. C. and treated with a current of air, steam or inert gas, preferably at 225 to 250 deg. C., until gelatinized. It is then cooled to 100 deg. C. and mixed with 300 parts of untreated oil, and into every 100 parts of this product 300 parts of aqueous liquid are vigorously stirred. This process is stated to be applicable generally to fatty oils containing linolic, linoleic or linolenic acid such as linseed, soya, cottonseed, sesame and ground-nut oils. (Br. Pat. 187,299. E. V. Schou, Palsgaard, Denmark. Dec. 13, 1922.)

Sewage Disposal—In order to obtain, in a relatively short period, an effluent of sufficient purity to allow of its being discharged into a river or estuary, the sewage to be treated is mixed with highly active sludge for a period of from 10 to 60 minutes in a tank provided with mechanical circulators and baffles. It is then passed into a series of tanks in which it is further aërated by means of air diffusers at the bottoms of the tanks. The mixture of sludge and sewage is then led into settling tanks, where the effluent is drawn off. The sludge, which is now a mixture of the original sludge and the new sludge from the treated sewage, is conveyed into a series of aërating tanks provided with air diffusers, and in these tanks the sludge again becomes highly active, the period of aëration being about 4 to 8 hours. From the last of the series of aërating tanks, the sludge is run to settling tanks, where more water is drained from it, the concentrated sludge being collected in a tank from which it is drawn by a pump and delivered to the initial mixing tank near the sewage entry pipe. (Br. Pat. 187,315. J. A. Coombs and Activated Sludge, Ltd., Westminster. Dec. 13, 1922.)

Desulphurizing Gases—Sulphuretted hydrogen is removed from gases by washing with a nickel salt solution with or without the addition of a salt incapable of precipitating nickel, or of a substance capable of forming a nickel compound soluble in alkaline solutions. The following substances are mentioned as being suitable: Ammonia, pyridine, salts of organic acids, ammonium chloride, ammonium sulphate and sodium chloride. When the sulphuretted hydrogen has been absorbed, with the formation of a precipitate of nickel sulphide, air is blown in, with the production of free sulphur and of a nickel solution suitable for re-use. An example describes the use of a solution containing nickel sulphate, ammonia and ammonium sulphate. (Br. Pat. 186,316. Ges. für Kohlentechnik, Dortmund. Nov. 15, 1922.)

Alloys—Bronze alloys, suitable for making articles for use in contact with superheated steam, wires for paper manufacture, springs for press-buttons, electric switches, and other purposes, consist of not less than 87 parts of copper, 4.5 to 10 parts of tin, 1 to 5 parts of nickel and not more than 5 parts of zinc. The copper and nickel are first melted together, the tin is then added, and finally the zinc.

A second specification by the same patentee covers a copper-zinc alloy having less than 40 per cent of zinc containing also nickel, manganese and iron, and not more than 3 per cent of aluminum. The alloy may consist of 40 to 55 parts of copper, 3 to 15 parts of

nickel, 1 to 3 parts of manganese, 1 to 2 parts of iron, 0.5 to 3 parts of aluminum, and less than 40 parts of zinc. The copper, nickel, manganese and iron are first melted together, the zinc then added, and finally the aluminum. (Br. Pats. 186,336 and 186,337. Allgemeines Deutsches Metallwerk Ges., Berlin. Nov. 15, 1922.)

Motor Fuel—Fuel oil for internal-combustion engines comprises an intimate mixture of mineral hydrocarbon oils, of 0.865 to 0.895 specific gravity, resin oil or oil derived from heating resin or a resinous body, and water, with or without distilled or recovered grease, fatty oils, tar distillates or cracked or polymerized mineral oil, the constituents being incorporated by ammonia or trimethylamine. The resinous and fatty constituents may be nitrated or sulphonated. The tar distillates used contain tar acids and boil between 250 and 280 deg. C. One example comprises 65 parts of kerosene, 10 to 12 parts of resin oil, or of a mixture of 20 to 30 per cent of resinous and 80 to 70 per cent of fatty oils, 2 to 5 parts of ammonia and 20 parts of water. (Br. Pat. 186,106. T. M. Hickman, Wolverhampton. Nov 15, 1922.)

Book Reviews

THE SMITHSONIAN INSTITUTION'S STUDY OF NATURAL RESOURCES APPLIED TO PENNSYLVANIA'S RESOURCES. By *Samuel S. Wyer*, consulting engineer, Columbus, Ohio. Published for and distributed by the Smithsonian Institution, Washington. 1922. 150 9x12-in. pages, including nearly 100 full-page illustrations, maps or charts.

The State of Pennsylvania has undertaken to give to the grade schools and high schools special instructions regarding the natural resources of the state and the utilization of these resources by industry. In furtherance of this idea, this volume has been prepared and is to be placed in the hands of every seventh grade geography teacher of the state, and will be distributed as well to others who will use it for instruction purposes. However, the value of the work is not by any means limited to that state nor to educational purposes.

The author has given a splendid and a detailed review of fuel, mineral, forest and agricultural resources as well as a special exposition of some of the metallurgical and mineral industrial development of the state. Mr. Wyer has been, in his many publications, exceptionally successful in graphic presentation and clear demonstration of important industrial and economic facts by maps, charts and photographs. This particular volume seems to be a superlative exhibition of this unusual skill, for the many illustrations are in themselves of such great value that without the text the book would be of great interest.

Of necessity the technical information furnished in such a book is not new, but the methods of presentation are in many cases novel and worthy of consideration by any engineer. The photographs and diagrams of industrial processes and plants are in general either diagrammatic or developed from models such as those exhibited by the Smithsonian Institution. Anyone having an industrial demonstration to make of any of the industries covered in this book will do well to consult this work both for material and for suggestions as to methods of presentation. It is to be hoped that the Smithsonian Institution will find it possible to extend its work of this sort until every state of the Union can be served by as fine a book as this one for Pennsylvania.

R. S. McBRIDE.

THE ANALYSIS OF RUBBER. By *John B. Tuttle*. 155 pp. Chemical Catalog Co., New York. Price, $2.50.

It is the author's intention that his monograph serve a two-fold purpose, namely, a guide to those chemists unfamiliar with rubber who may be called upon to analyze this type of product, and, for the benefit of the rubber technologist.

The book in general is of little, if any, value to a rubber technologist. The chapter dealing with the testing of crude rubber is entirely too limited and the methods outlined cannot be successfully used to differentiate between non-uniformity of shipments either from the standpoint of rate of cure or quality variation. The same applies to that part dealing with the sampling and testing of the various reinforcing and diluent pigments. In many cases the tests given are incapable of interpretation as far as their effects on the resultant compound is concerned, while in others some particular test of much importance is neglected.

A few instances may be mentioned, such as in the examination of oil substitutes (page 29) where the acetone extract is made for eight hours only, of mineral rubber (page 31) which determines the "acetone soluble" in four hours and makes no reference to the melting point of plasticity, of litharge (page 42) which is not examined for metallic lead and of gas black (page 48) where no reference is made to a test for grit.

Throughout, there is a tendency on the part of the author to endeavor to explain the effects and uses of the compounding pigments in rubber, which seem to indicate a lack of experience along this particular line, inasmuch as many statements conflict with present practice. He refers to magnesium carbonate (page 45) as not being as powerful an accelerator as the oxide, whereas it has no accelerating value, to aluminum flake (page 46) being used to replace zinc oxide, to mineral rubber (page 30) reducing blooming, and to air slaked lime hydroxide (page 51) as having but some accelerating effect. These are but few instances of many such statements to which exceptions may be taken.

It would have been well to have left out any reference to organic accelerators, or at least confined their mention to name only, as serious misconceptions may be formed by a close study of this particular chapter, a noticeable example of which is the statement that p-phenylene-diamine is of no importance commercially (page 40).

When the value of this monograph to the non-rubber technologist is considered it probably serves its purpose to some extent. However, it adds nothing to what has already been published along these lines, particularly by the various committees of several technical societies. It has, however, the advantage of having in compact form many data which are otherwise quite scattered as well as many references to work on rubber.

It may be well to call attention to the fact that the book does not seem to have been thoroughly proof-read. A particularly bad example is on page 25, where it states to "divide the percentage of rubber by the percentage of combined sulphur," whereas the opposite is the procedure, namely, dividing the sulphur by the rubber.

F. J. DUGAN.

THE ROMANCE OF THE GAS INDUSTRY. By *Oscar E. Norman*, librarian and superintendent of training and education, Peoples Gas, Light & Coke Co., Chicago. Privately published and for distribution by the author. 200 pages, including many illustrations. Price, $1.50.

As implied by its title this book is intended to popularize many of the historical and dramatic features of the gas industry and record in part "the romance of its achievements." "An attempt has also been made to relate entertainingly how obstacles in the way of production, distribution and uses of gas have been overcome; how gas has become the ideal fuel in the household and in the factory; and how its radiance rivals the sun."

The author has succeeded in bringing together many interesting items regarding the early history of the manufactured gas business; and he clearly sets forth some of its present day problems, quite obviously in an effort to defend the industry against some of the common misapprehensions and criticisms.

Starting as it does with the beginning of the universe and tracing some of the early stages of civilization through the worship of fire to the discovery of practical applications of gas in the household, the book attempts a most difficult task. As presented, it is doubtful whether the general reader would find a great deal of interest or value to him; but many in the gas business itself will doubtless be inspired to greater enthusiasm for the industry and may receive from the book suggestions as how diplomatically to meet public-policy problems which repeatedly tax the ability of even the most ingenious management. Particularly for the information of the young employee during his course of instruction as a cadet, this work should find general usefulness.

R. S. McBRIDE.

at from 200 to 500 deg. as mentioned above in suitable converters, the carbon dioxide being returned to the process to liberate more hydrocyanic acid from another batch. (1,439,909. F. J. Metzger, assignor to the Air Reduction Co. of New York. Dec. 26, 1922.)

Purification of Hydrofluoric Acid—Henry Howard has assigned to the Grasselli Chemical Co. a process for the purification of hydrofluoric acid. It consists of bubbling the gases evolved by the action of sulphuric acid on fluorspar through a tower containing potassium sulphate solution. The silicon fluoride or hydrofluosilicic acid, which is the principal impurity, is washed out and the hydrofluoric acid is passed on. Engineers Honor Caetani at Banquet

Distinguished Gathering Hears New Italian Ambassador's Message of Good Will—Engineer Needed in Public Life

POLITICS needs a larger dose of logic and practical sense, Prince Gelasio Caetani, new Italian Ambassador to the United States, declared in an address at the annual dinner of the American Engineering Council of the Federated American Engineering Societies held at the Chevy Chase Club, Washington, Thursday evening, Jan. 11. These qualities of the engineer, he said, would bring great advantages to public affairs.

The Ambassador, himself an engineer and for 13 years previous to the war a resident of the United States, said that his principal aim is to strengthen the bonds of friendship and esteem between this country and Italy. Recalling his engineering career in the West following his graduation from the Columbia University School of Mines in 1903, Prince Caetani said that he was returning not only as a diplomat but as an engineer and friend of America.

Engineering, he continued, is destined to play a powerful rôle in modern civilization. Italy he described as a nation born again. Its potentialities industrially, he said, were bound to make it a great force in world commerce. The electric industry especially was making rapid strides and all branches of engineering activity were developing constructive effort, in which Italy's greatest asset was an abundance of efficient labor and in which American capital and machinery were needed.

The Ambassador's address was heard by leading engineers and public officials from all parts of the country. Dean Mortimer E. Cooley of the University of Michigan, president of the American Engineering Council, presided. Other speakers were Calvin W. Rice of New York, secretary of the American Society of Mechanical Engineers, and John J. Tigert, United States Commissioner of Education.

Pan-American Unity

Mr. Rice, who recently returned from South America, where, accompanying Secretary Hughes and party to the Brazilian Centennial Exposition, he acted as an envoy of the American engineering profession, said that definite steps have been taken to promote Pan-American unity among engineers. Through the efforts of the Department of Commerce, Mr. Rice reported, the idea of standardization was spreading in the South American countries, all of which are contemplating legislation to establish a standardization bureau, as recommended by Secretary Hoover.

A permanent organization to carry out the resolutions of the recent International Engineering Congress at Rio de Janeiro has been effected, according to Mr. Rice, who said it was now proposed to call a meeting of the Pan-American nations to develop the dream of a transcontinental railway. He predicted that the engineer would be increasingly influential in bringing about

GELASIO CAETANI
Mining Engineer and Newly Appointed Italian Ambassador

Pan American solidarity and in the attainment of international peace.

Engineering in Japan

Elmer A. Sperry of New York, reporting upon his mission to Japan, told of the remarkable progress being made by the Japanese in industry and in engineering, saying that even England had come to Tokio to gain new ideas in warship construction. Mr. Sperry described the huge size of the industrial plants and machinery used in Japan as exceeding anything known in the United States. The Japanese people, he said, were keeping the disarmament compact to the letter, while the engineers of Japan were aiming to promote a better international understanding by effecting closer relations with the engineers of other nations.

Caetani's Address

The Italian Ambassador was warmly received by his fellow engineers, and his remarks were frequently applauded. Extracts from his speech follow:

"Your kind invitation to be a guest at the annual banquet of the Federation of American Engineering Societies reached me while I was preparing to leave for the United States. I read it with deep satisfaction, for it made me feel that, besides sailing for America as Italy's Ambassador, I was going home to my old stamping grounds somewhat still invested with the qualifications of an engineer.

"We pride ourselves in saying: 'Once an engineer, always an engineer.' Whatever may be the course of life followed by one of us, it will always be marked by the indelible seal of the scientific, practical and logical training to which an engineer is subjected during the early years of life.

"I judge that many of my colleagues present at this banquet have followed in life most disparate occupations which often had little to do with engineering; such has been my personal experience during the agitated years since the beginning of the war. Well, gentlemen, we can say that in each and every occupation we have felt and thought and acted chiefly as engineers.

"Some have made the remark in criticism that engineers lack political intuition and ability; I would answer that a larger dose of logic and positiveness applied to politics would bring great advantages to public affairs.

"Whatever the case may be, it is very agreeable that politics bear little weight in the relations between Italy and the United States. Between our two countries there has never existed political rivalry or serious commercial competition; our relations have been confined almost exclusively to contacts of labor, of engineering, of commerce, of science and of art.

"Italy's largest asset is the remarkable quality of its people's labor; sober, intelligent, hardworking and plastic, the Italian peasant or workman will in an incredibly short time become efficient in whatever he is called to do. While I was carrying out fortification works along our front, many officers of the allied powers expressed to me their admiration for the remarkable skill of our peasant-soldiers compared with their own.

"Of all this many Americans are perhaps not yet fully aware for the reason that the wave of Italian emigration which shortly preceded the war was so sudden that it was not utilized to best advantage. Most of our skillful laborers, insufficiently guided, agglomerated in the congested cities of the East, contenting themselves with the first job they came across, instead of taking up occupations more congenial to their nature and for which they were better prepared.

"Specialization of Italian labor will bring great advantages to the large engineering industrial and agricultural enterprises which are still to be achieved in the United States.

Italy's Natural Resources

"Much, however, is still to be done in Italy itself; its resources are far from being fully developed and there are many opportunities for American capital, machinery and technical organization to be usefully applied in Italy.

"The electric industry in our country has made rapid strides and as to percentage of utilized water power, Italy ranks, I believe, foremost in the world. Electricity is our 'white coal' and at the present day its use results in an economy of about two billion lire, otherwise necessarily spent on fuel imports.

"In 1898 the electric energy developed in Italy amounted only to 87,000 kw.; it increased to 426,000 kw. in 1908, to 1,240,000 kw. in 1918 and power plants for some other 1,000,000 kw. are planned

or under construction. About 800,000 kw. are still to be developed.

"On the Tirso in Sardegna a reservoir of 416 million cu.m. capacity is being constructed. It will be the second largest in the world, ranging immediately after the Assuan dam and will develop about 50 million kw.-hr. and irrigate 60,000 acres of land.

"My experience in the United States has been my most valuable asset in life. Before leaving Rome, at a dinner given to me by the Italian engineers, I exhorted the young engineers to get a few years of practical training in America. I hope you will do likewise by encouraging your students and graduates to spend some time in Italy, as nothing broadens the mind more than to breathe an atmosphere different from that of one's own town and country.

"Italy's atmosphere is vibrating with wonderful reflexes of a long and glorious past and full of promise for a remarkable future.

"It is a great art in life to single out and appreciate other people's good qualities and try to make them your own.

"Similar intercourse between our young students who, in a few years, will be the active men of our countries, will be a powerful factor in reaching the principal and ultimate aim I will have in view in carrying out my duty as Ambassador—that is, to strengthen the bonds of friendship and esteem between Italy and the United States."

Would Continue to Hold Foundation Patents

Department of Justice Asks Provision in Winslow Bill to Exclude Chemical Patents From Returned Alien Property

The Department of Justice is urging that a safeguarding clause be inserted in the Winslow bill, which authorizes the restoration of $10,000 trusts held by the Alien Property Custodian to their German and ex-enemy owners, specifically excluding the 4,700 patents which are now held by the Chemical Foundation. H. J. Galloway, special assistant to the Attorney-General, informed the committee last week that the government desired to have this additional protection in order that the patents, listed at nominal valuations, might not be turned back.

Present indications are that the government's motion to get back the Chemical Foundation patents will be heard in the District Court of Delaware about April 15, Mr. Galloway said. He informed the House Interstate and Foreign Commerce Committee, which had been conducting hearings on the Winslow bill, that all of the necessary preliminary legal papers had been filed and that only the fixing of the date of argument held up consideration of the case.

"If the Chemical Foundation has any title at all to the ex-German patents, it is an absolute title," Mr. Galloway said. However, he contended that the sum paid for the patents was inadequate and that Francis P. Garvan, when Alien Property Custodian, had arranged for the sale of the patents to the Chemical Foundation, so that he stood in the position of both buyer and seller.

This, Mr. Galloway said, was manifestly lacking in equity. The value of the patents, he said, had been variously estimated from $10,000,000 to $100,000,000, one patent for neosalvarsan being worth more than the total amount paid for all of the German patents.

The Department of Justice wants Congress, in passing any legislation dealing with the question of alien property, to exclude the patents held by the Chemical Foundation, but Mr. Galloway made plain that it desired to have the rights of the American industries now using them under a license plan to have ample protection. If the patents are restored it will be up to Congress to direct what is to be done with them.

Engineering Council Reviews Accomplishments

Encourages Participation of Professional Men in Public Affairs

The engineering profession is on the eve of great developments, Dean Mortimer E. Cooley of the University of Michigan declared in his address to the American Engineering Council of the Federated American Engineering Societies at the annual meeting of the Council held at the Cosmos Club in Washington, Jan. 11 and 12. Dean Cooley, who was unanimously re-elected president of the Council for 1923, struck the keynote of the gathering in saying:

"We are, I feel, entering upon a new era. The engineer, not so much in the technical as in the social sense, is about to take that part in the world which rightfully is his. I am speaking not of civil engineering, mechanical engineering, chemical engineering, electrical engineering or any other branch of engineering, but of the engineering profession as a whole."

Dean Cooley, reviewing the year's work, said that substantial results had been achieved, and that the Federation was progressing gradually and surely toward the fulfillment of its mission. His trip through eighteen states last spring, he said, inspired the conviction that the Federation was a necessary instrument of organized engineering and a source of opportunity for service both within and without the profession that exceeded the hopes even of its founders. The waste report and the report on the two-shift day in continuous industry he characterized as two outstanding accomplishments of world importance. The two-shift report is now available in printed form, and the committee which prepared it has been formally discharged by the executive board of the Council. A third undertaking of similar magnitude was likely to be set in motion in the near future, Dean Cooley announced.

The report of Executive Secretary L. W. Wallace, who was re-elected by the executive board, showed that the activities of the Federation are multiplying rapidly. Relations with government departments are becoming more extensive and more intimate and in every direction the Federation is winning increased recognition. A letter from Secretary Hoover, read at the meeting, asserted that the Federation was one of the most influential existing agencies in the promotion of public good.

Federal legislation in which the Federation through the executive secretary has taken an active interest includes the Sterling-Lehlbach bill, topographic mapping, helium, national hydraulic laboratory and revision of the mining laws. John R. Freeman was the principal witness at the hearings on the question of a national hydraulic laboratory, the need for which he pointed out in an exhaustive report. Mr. Wallace asserted that the bill for mining law revision should receive the active attention of all engineers. Adoption of an amendment increasing the appropriation for topographic mapping from $325,000 to $500,000 was called by Mr. Wallace "a distinct victory auguring well for the Temple bill." He reported a tendency to delay action on the Sterling-Lehlbach bill, and this he described as unfortunate.

Engineering Ideals

A report of the committee on engineering ideals, expressing the desire of the Federation to bring to the attention of the engineering colleges throughout the country the need of pointing engineers toward leadership in public affairs, was adopted. The committee was headed by Prof. Joseph W. Roe of New York University. The Council adopted the report of its patents committee requesting "that a joint commission be appointed by the Senate and House of Representatives to investigate the needs of the Patent Office, as to both personnel and physical equipment, and that it be requested to report at an early date, so that the present session of Congress may take appropriate action."

At the suggestion of the Spokane Engineers Club, transmitted through J. C. Ralston, the Council voted to refer to its committee on public affairs with its indorsement a proposal to recommend to President Harding the selection of "the engineering type of man" as Secretary of the Interior to succeed Mr. Fall, who has resigned. J. Parke Channing, head of the committee, supported this proposal, saying that it was in keeping with the engineering movement to establish a Department of Public Works. Eighty per cent of the activities of the Interior Department, it was asserted, concern engineering problems. The speakers made it plain that no political considerations were involved.

Vice-presidents were elected by the Council as follows: J. Parke Channing and Calvert Townley, New York; Philip N. Moore, St. Louis; Gardner S. Williams, Grand Rapids, Mich. H. E. Howe of Washington was elected treasurer.

Fertilizer Man Attacks Ford Shoals Offer

C. H. MacDowell Points Out Effect on Water Power Act in Establishing Such a Precedent

Vigorous opposition to acceptance of Henry Ford's proposal for purchase of the Muscle Shoals government project was voiced in an address before the Chicago Woman's Club in Chicago, last week, by C. H. MacDowell of the Armour Fertilizer Works.

"The Ford proposal, if accepted, nullifies the fifty-year clause of the water power act," said Mr. MacDowell. "The government builds the plants, while the Ford company pays no taxes on the costs and takes no risk of the dams holding.

"The company acquires special privileges and subsidies from the government which enable it to compete unfairly with companies putting up their own funds. It obtains a private power monopoly for 100 years or more and obtains a strangle hold on the industrial development of that section through its power control. Certainly a large block of economic power to be entrusted to the administration of a private company!"

Danger of Special Legislation

Mr. MacDowell pointed out that the Federal Trade Commission, in its second annual report, forcibly draws the attention of Congress to the danger of special legislation, the effect of which must be nullification of the national policy in respect to water power, which has been declared by Congress after investigation and study covering more than a decade.

"The commission does not mention by name Muscle Shoals or the Ford proposal," he continued, "but it could have meant nothing else in the following statement:

"'There are movements on foot in several quarters to secure for certain sites or streams special legislation which if approved would constitute a partial repeal of the federal water power act, and would eventually result in the progressive disintegration of our present national water power policy.'"

Will Attempt to Collect Literature on Cellulose

Dr. C. J. West, chairman of the committee on bibliographies of the Technical Association of the Pulp and Paper Industry, has offered to act for the cellulose division of the American Chemical Society as a receiving center for bibliographies relating to any branch of cellulose chemistry. It is hoped that all of those having such bibliographies will send a copy to Dr. West, National Research Council, 701 Massachusetts Avenue, N.W., Washington, D. C. Dr. West has kindly offered to assemble all material received and make it available to anyone interested. It is hoped that a large amount of duplication of effort can be avoided in this way.

Tear Gas Adopted by Washington Police Force for Mob Control

Police and other officials of the District of Columbia had a striking demonstration of the effectiveness of tear gas when one of the guns recently invented by Captain L. M. McBride, of the Chemical Warfare Service, was accidentally opened in the office of the chief of police. The chief himself was temporarily blinded, as were a number of employees in the District Building. The gas found its way into the halls and elevator shafts, with the result that hundreds of persons participated in this accidental demonstration of its effectiveness.

As a result of this incident, it was revealed that the Washington police department is equipping all patrol wagons, police stations and jails with this gun.

Reported Used by Burglars

Officers of the Chemical Warfare Service are impressed with the significance of the report that the theft of the Schoellkopf jewels in New York City was made possible by the use of gas. If the use of gas is found to be effective in the highly practical art of burglary, it is believed that the police and military authorities will be more ready to admit that the Chemical Warfare Service has developed an agent with the greatest potentialities in the control of mobs and other law breakers.

Agricultural Chemists Develop Poison for Barberry Bush

Intensive experiments on the part of the office of cereal investigations of the Department of Agriculture has developed two chemical methods for the eradication of the barberry bush. This bush spreads a rust to grains and grasses. A campaign is now in progress throughout New England and the Middle West looking to the eradication of this growth. More than forty chemicals were tried in the experiments. It has been found that rock salt and sodium arsenite give uniformly good results. It is anticipated that large quantities of these materials will be employed in future eradication work.

Under-Fertilization of German Farms Promises Demand for Chilean Nitrate

During 1922 Germany used some 350,000 metric tons of atmospheric nitrogen for agricultural purposes. To this may be added not more than 100,000 tons of Chilean nitrate. This indicates that German farms are being under-fertilized by 40 per cent.

Since no important expansion of atmospheric nitrogen production is expected in the near future, the general opinion in Germany is that there should be large importations of Chilean nitrate this year. Indications are that an active effort now is being made to provide for the financing of large purchases.

F. C. Brown Made Head of Bureau of Standards

Assistant Director Assigned Temporarily to Post Vacated by Stratton

Since a considerable period is likely to elapse before a director will be chosen for the U. S. Bureau of Standards, importance is attached to the designation by Secretary Hoover of Dr. Fay C. Brown as the acting director, who will direct the work of this important subdivision of the Department of Commerce during the interim.

Dr. Brown was born in Washington, Ohio, in 1881. He was graduated from the University of Indiana, in 1903. He did graduate work at the University of Illinois, at the University of Chicago and at Princeton. After taking his doctor's degree at Princeton in 1908, he did further work at that institution as an Ogden Fellow. On the completion of that work he accepted a position as instructor in physics and engineering at the University of Illinois. Later he joined the faculty of the University of Iowa. He was engaged in that work when the United States entered the war. He entered the military service and was assigned to the Ordnance Department, where he was placed in charge of the testing and ballistic work on airplane bombs. While in the military service he attained the rank of major.

At the end of the war, Dr. Brown had the opportunity to choose between the professorship of physics at the University of Iowa and the position of assistant director of the Bureau of Standards. He accepted the latter post where he has been engaged continuously since.

Accomplishments in Research

While Dr. Brown regards as his principal achievement the work that he has done in directing the Bureau which Secretary Hoover likes to refer to as "the largest physical laboratory in the world," he has done a great deal of research in addition to his administrative duties. He is proud of his work in thermionics, since that proved to be a sort of forerunner of radio amplification. He did important optical work and has made an intensive study of the electrical and mechanical properties of selenium and selenium crystals. With Joel Stebbins, the astronomer, he took an important part in starting the work on the mechanical measurement of the intensity of double stars.

Wages Cut in Austrian Chemical Industry

Wages in the Austrian chemical industry were cut 11 per cent on Dec. 1, according to advices sent the Department of Commerce from Vienna. The difficulties of the chemical trade have been increased by the action of German chemical manufacturers in declining to extend credit to Austrian firms for longer than 30 days and by their demand for partial or full payment of the order, in some cases at the time it is placed.

Federal Suit Instituted Against Butterworth-Judson Corporation

Heavy Chemical Company Called to Account for Expenditure on War-Time Picric Acid Plant

THE FIRST of a series of suits to be brought by the government to recover damages on war contracts was instituted last week in the federal court of New York. The suit was brought at the instance of Attorney-General Daugherty and Colonel William Hayward, Federal Attorney, through Victor House, Assistant United States District Attorney.

In the initial suit Mr. House directs that Henry G. Atha, James O'Grady and Thomas G. Haight, receivers in equity for the Butterworth-Judson Corporation, account for $1,151,000 expended by the corporation from a revolving fund of $1,500,000 advanced by the government.

History of Picric Acid Plant

According to Mr. House the revolving fund was advanced on a contract consummated by the government with the Butterworth-Judson Corporation in May, 1918, for the construction of a plant at New Brunswick, Ga., by the defendant corporation, for the manufacture of 72,000,000 lb. of picric acid. The construction was to cost $7,000,000. Approximately $8,500,000 was expended and the plant was about 50 per cent completed when the contract was terminated by the cessation of hostilities.

In April creditors instituted suits in New York and New Jersey for the designation of a receiver for the defendant corporation, it being alleged it was unable to satisfy maturing obligations.

Funds Were Banked

It is alleged by the government that the revolving fund advanced to the defendant was partially deposited with various banks in this city, which Mr. House contends was a wrongful conversion of trust funds, and that the banks are not entitled to retention of the deposits.

At the time of the suit for a receiver the defendant corporation had $528,009 deposited with the Chase National Bank, American Exchange National Bank, New York Trust Company and National Newark & Essex Banking Company.

Discussing the suit Mr. House said: "When the advance of $1,500,000 was made the government required a surety company bond conditioned upon an appropriate accounting of the advance. Eight surety companies joined in this bond, the American Surety Company of New York being the company through which it was written. These surety companies are joined as parties defendant, and the court is asked to direct them to pay any balance of the $1,500,000 not otherwise paid."

The main Butterworth-Judson plant is located in Newark, N. J. There has been a large depreciaiton in the value of the plant since the war ended. It is being operated by the receivers, who recently received authority from the court to enter into contracts for the coming year. It is understood that reorganization is being planned.

Company Asks Damages

The original contract provided that if it were terminated before 18,000,000 lb. of picric acid were delivered, the contractor should become entitled to liquidated damages of 3 cents a pound on the undelivered portion of such 18,000,000 lb.

No picric acid was ever manufactured or delivered under the contract, and one of the large items of dispute in this suit is whether the Butterworth-Judson Corporation is entitled to $540,000 as liquidated damages under the termination clause of the contract. The government will contend that this provision for liquidated damages was not intended to become operative unless the plant was completed and deliveries of picric acid under the contract had been begun prior to the termination of the contract.

French Consider Compulsory Use of Alcohol in Motor Fuel

France is considering the establishment of a Bureau of Alcohol in one of its Federal departments, according to advices to the Department of Commerce.

In addition, legislation practically is assured which will require the admixture of at least 10 per cent of alcohol with all motor fuel. Reports have been submitted by chemists to the Chamber of Deputies setting forth that a mixture of 45 to 55 per cent alcohol can be used in automobile engines without any change from the designs now using gasoline only.

Fiber Companies Merge

The American Vulcanized Fiber Co., the Keystone Fiber Co., both of Wilmington, Del., and the National Fiber & Insulation Co., Yorklyn, Del., have been merged under the name of the National Fiber Co. Headquarters will be maintained at Wilmington, and present plants there and at Yorklyn and Newark, Del., will be continued in operation. J. Warren Marshall, formerly head of the National Fiber & Insulation Co., has been elected president of the new organization; Claude W. Sutton, heretofore head of the American Vulcanized Fiber Co., will be vice-president of the consolidated company, in charge of sales.

Engineers Urge National Hydraulic Laboratory

Hearty support for a national hydraulic laboratory is coming from all parts of the country and from the men engaged in all branches of engineering, the Senate sub-committee was told during the course of a hearing on January 10, at which Senator Ransdell's bill providing for the establishment of a National Hydraulic Laboratory was considered. The principal testimony was given by John Lyle Harrington, of Kansas City, the president of the American Society of Mechanical Engineers; Gardiner S. Williams, of Detroit, a hydraulic engineer, and John C. Ralston, of Spokane, Wash., a civil engineer.

The sub-committee was told that all branches of engineering are coming to attach greatly increased importance to research. The hydraulic laboratory would do much to supplant rough and ready knowledge of hydraulic formulas and practice by exact knowledge, it was said. Mr. Harrington cited a number of specific cases in which there have been wide divergences of engineering opinion on fundamental problems in hydraulics. In each of these cases the completion of the work demonstrated absolutely that certain theories advanced by eminent engineers were wrong. These differences never would have arisen had accurate basic information been available. As it is, Mr Harrington told the Senators, most hydraulic problems are solved by the application of judgment rather than in a scientific manner. Were it possible to reduce the margin to provide for the unknown, great economies could be effected in the construction of flood control works, he asserted.

Accurate Formulas Lacking

Mr. Williams referred to the existing controversy among engineers over the spillway problem at New Orleans, as being typical of the great dearth of scientific data which can be applied to the control of rivers. He is at a loss to undestand, he said, why there should be opposition to a national hydraulic laboratory from the Corps of Engineers—the agency which would benefit most from its operation. The Mississippi River Commission, he declared, would benefit particularly, as he believes many of their theories could be proven absolutely if studied at such a laboratory.

The committee was told that hydraulic formulas are not of scientific character. There is need, it is stated, for research work on all the problems of water, but since such a laboratory must be confined in the start to the more pressing problems, it was predicted that its early work would be confined to the problems of river hydraulics. It was suggested that the laboratory should be made available to the engineering societies and to individual engineers for the working out of special problems, in addition to those which come before the Corps of Engineers, the Geological Survey, the Bureau of Standards, and the Reclamation Service.

Engineers Plan World Congress in 1926

Sesqui-Centennial Exposition in Philadelphia to Be Scene of International Meeting

A conference on the plans for an international engineering congress, to be held at the time of the Sesqui-Centennial celebration in Philadelphia, was held in New York City, Jan. 9. The meeting was called to order by Richard L. Humphrey, chairman, who outlined the purposes of the conference and reviewed briefly the events leading to the calling of the meeting.

The movement to hold a world congress of engineers in 1926 was initiated by the Engineers Club of Philadelphia in December, 1921, and at that time an invitation was extended to the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials. Each was requested to appoint two representatives to meet with a committee of the Engineers Club in Philadelphia to formulate a plan for such a world congress.

An outline of the plan of organization for such a congress was prepared by the secretaries of the four founder societies in May, 1922, and was subsequently approved by the presidents of these societies. This plan proposed a board of management, which was duly elected, at an organization meeting in November, 1922 George S. Webster was appointed temporary chairman and Charles E. Billin temporary secretary.

Will Promote Welfare of Profession

At the meeting last week the committee considered the advisable scope of the congress, methods of financing, relation of meetings of engineering societies to the sessions of such a congress and publicity.

It was brought out in the discussion that this meeting represents another step toward bringing the engineers of the different countries of the world closer together, taking up the threads of contact that had been broken by the war and fostering a better understanding of the relation of the engineer not only to the technical problems of the world, but to the reconstruction of our present day civilization, to which the engineer has already contributed so much in a material way.

Personal

RICHARD V. AGETON, of the Bureau of Mines staff, who has been doing examination work for the War Minerals Relief Commission, is acting as assistant chief mining engineer of the Bureau of Mines.

Dr. RAYMOND F. BACON and Dr. J. ENRICO ZANETTI have been presented with Distinguished Service Medals for their services in France. Dr. Bacon was Colonel of the Technical Division, Chemical Warfare Service, American Expeditionary Forces, and Dr. Zanetti was Lieutenant Colonel, Liaison Officer, Chemical Warfare Service, American Expeditionary Forces. Presentation was made by General Bullard, Governors Island, New York.

Dr. H. E. BARNARD, director of the American Institute of Baking, spoke before the Indiana Section of the American Chemical Society, Jan. 9, on "The Possibilities of Chemical Research in the Baking Industry."

E. L. BULLOCK of New York, formerly an official of Katzenbach & Bullock, manufacturers of chemicals, and recently connected with the Tidewater Chemical Co., New York, has resigned from the latter company.

M. R. CAMPBELL will serve as acting director of the United States Geological Survey during the absence from Washington of Philip S. Smith.

EDMUND S. DAVENPORT, formerly research metallurgist of the Eastern Malleable Iron Co., Naugatuck, Conn., is now with the Westinghouse Lamp Co., Bloomfield, N. J.

Dr. THOMAS B. DOWNEY is the present incumbent of the industrial fellowship in the Mellon Institute of Industrial Research of the University of Pittsburgh, established by the Edible Gelatine Manufacturers of America, Inc., for the purpose of ascertaining the real food value of edible gelatine in the American dietary. In addition to experimental investigations, a correlation of available facts regarding edible gelatine will be made, to be held at the disposal of all users.

Brigadier-General AMOS A. FRIES, chief of the Chemical Warfare Service, spoke before the Engineers Club, Baltimore, Jan. 9, on "Gases Used in Warfare Protection Against Them and Their Peace-Time Uses."

Dr. MORRIS S. KHARASCH, formerly national research fellow in organic chemistry at the University of Chicago, has been appointed associate professor of organic chemistry at the University of Maryland.

Dr. RICHARD C. LORD, at one time instructor at Washington and Lee University and later engaged in industrial chemistry, has been elected assistant professor of chemistry and physics at Kenyon College, Gambier, Ohio.

Dr. E. Z. LYNN of the college of pharmacy, University of Washington, Seattle, gave an interesting address at a recent meeting of the Puget Sound Section of the American Chemical Society on "The Manufacture of Zinc and Barium Products."

S. JOSEPH MCGRATH, formerly head chemist for the Obrien Varnish Co. of South Bend, Ind., has been appointed superintendent of the Phelan Varnish Co. of St. Louis, Mo.

Dr. JOSIAH H. PENNIMAN was elected provost of the University of Pennsylvania, on Dec. 27, 1922. He has been acting provost since the resignation of Dr. Edgar Fahs Smith about three years ago.

Dr. OTTO M. SMITH, formerly in charge of research for the Roseville Chemical Co., Roseville, Indiana, has been appointed assistant professor in quantitative chemistry at Iowa State College, Ames, Iowa.

Prof. O. F. STAFFORD, head of the department of chemistry of the University of Oregon, has returned to his university work at Eugene, after a leave of absence of four years' duration devoted to industrial research in the field of waste wood utilization by destructive distillation.

E. B. SWANSON has been promoted to be administrative assistant to the Director of the Bureau of Mines. As private secretary to the Director, Mr. Swanson for some time has been discharging the duties of administrative assistant, without having had the title or the salary which goes with that position. Mr. Swanson is a graduate of the University of Washington.

F. G. THOMPSON of Seattle, Wash., has been elected chairman of the Puget Sound Section of the American Chemical Society at the annual meeting held at the University of Washington. A. G. Bissell has been elected vice-chairman; R. W. Ellison, secretary; G. C. Howard, treasurer, and H. K. Benson, councillor.

L. M. TOLMAN has been appointed technical director of Wilson & Co., following a reorganization of the company's technical and laboratory activities. The work of the chemical laboratory has been divided into two divisions: The Technical Division, with E. A. SCHLESSER in charge, and the Food and Sanitary Division, with F. W. KURK in charge. Mr. Tolman will continue to supervise the work of both divisions.

F. M. TURNER, JR., was elected a councillor of the New York Section of the American Chemical Society, and not F. M. Turner, as given on page 1190 of our Dec. 13 issue.

Dr. CHARLES D. WALCOTT, secretary of the Smithsonian Institution, president of the National Academy of Sciences, and formerly director of the United States Geological Survey, has been elected president of the American Association for the Advancement of Science.

Dr. E. R. WEIDLEIN, director of the Mellon Institute of Industrial Research, addressed the Indiana Section of the American Chemical Society, Jan. 12, on "The Value of Industrial Research."

The following men have been elected to membership in the Club de Engenharia (South America), which organization corresponds to an amalgamation of the four national societies in the United States: JOSIAH E. SPURR, LOUIS J. HIRT, VERNE L. HAVENS, A. W. K. BILLINGS, EDWARD WEGMANN, SAMUEL M. VAUCLAIN and CALVIN W. RICE.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

A Year of New Records in the Petroleum Industry

Crude Oil Output Exceeds Last Year's by 81,000,000 Bbl.—Daily Production Now Over 1,750,000 Bbl.

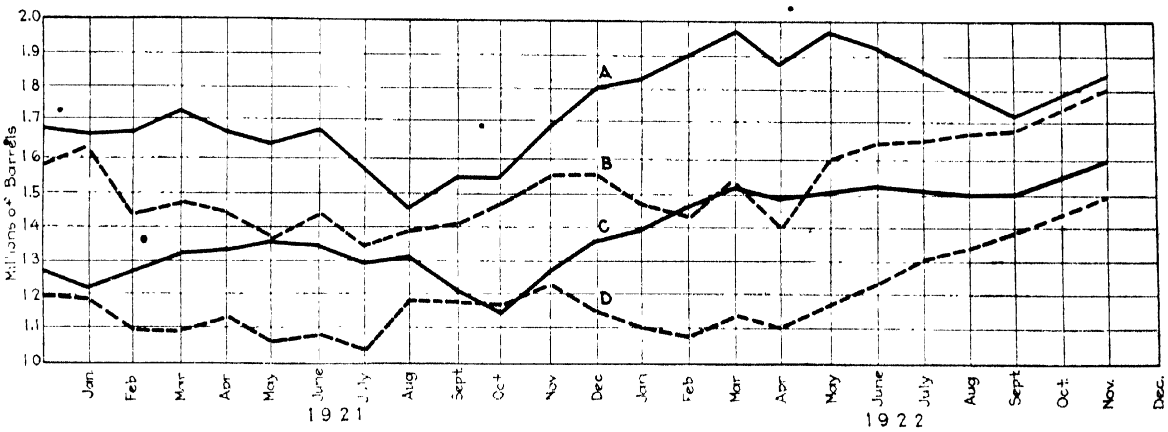
The year just closed has been a remarkable one for the oil industry. Crude oil production for 1922 probably exceeded 550,000,000 bbl.—a gain over 1921 of 17 per cent. Recently, for the first time in history the output of crude oil has reached 1,750,000 bbl. daily. The American Petroleum Institute has estimated that production for the week ended Jan. 6, 1923, averaged 1,752,000 bbl., as compared with 1,741,200 bbl. for the preceding week, an increase of 11,300 bbl.

The increase over last year, which has been explained largely by the declining production in Mexico, has come principally from Arkansas, California, Wyoming and Montana. A decrease in the central Texas field was more than offset by Oklahoma and California gains.

During the past few months the oil industry has witnessed an interesting race between domestic production and consumption. The recent demand for petroleum products has been equivalent to 1,700,000 bbl. per day. The supply has been amounting at times to over 1,900,000 bbl., the increment being due to imports from Mexico. The accumulation of stocks has brought the problem of oil storage to a very serious stage and during the coming year the industry will doubtless be forced to provide additional storage for crude oil.

The Monthly Averages

The statistics compiled by the United States Geological Survey are complete only for the first eleven months of the current year. During November the survey reports that the daily average production of petroleum (amounting to 1,596,300 barrels) increased 51,623 barrels; the daily average imports of crude and topped oil (amounting to 245,467 barrels) increased 6,499 barrels; the daily average exports of crude oil (amounting to 28,533 barrels) increased 4,630 barrels and the daily average consumption of crude petroleum (amounting to 1,781,433 barrels) increased 74,078 barrels, net results being that stocks increased 954,000 barrels. This is the smallest addition to storage that has been recorded for any month since September, 1920.



STATISTICS OF CRUDE PETROLEUM, JANUARY, 1921, TO DECEMBER, 1922

Daily Averages for—
(*A*) Domestic production of petroleum plus imports of "mineral crude oil."
(*B*) Consumption plus exports of domestic and imported petroleum.
(*C*) Domestic production (petroleum transported from producing properties).
(*D*) Consumption plus exports of domestic petroleum.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	171.71
Last week	172.79
January, 1922	144
January, 1921	181
January, 1920	242
April, 1918 (high)	286
April, 1921 (low)	140

The slightly lower price for cottonseed oil was sufficient to lower this week's index by one full point. Prices for practically all of the other commodities were well maintained.

New Corporation to Sell German Potash

Kalisyndikat Representative Announces Plans for a New Distributive Agency for North America

A potash-importing corporation to market the products of the German syndicate in the United States, Canada, Cuba and Porto Rico has been announced by A. Vogel, the American representative of the Deutsches Kalisyndikat, G.m.b.H. It is generally believed that this represents the first move in an effort to transfer the syndicate's business to an agency in this country, in order to put it on a dollar basis. Difficulties in exchange, reparations and inland taxes in Germany no doubt helped to prompt this action. It is further intimated that the move may be a part of the syndicate's plans for recapturing its pre-war monopoly, since it would be entirely possible to allow large American consuming interests to participate in the importing corporation and share in its profits.

Mr. Vogel's announcement is as follows:

> I herewith beg to announce that the Deutsches Kalisyndikat, G.m.b.H., Berlin, has entered into an agreement with the Potash Importing Corporation, 42 Broadway, New York, whereby the corporation undertakes to market and distribute the syndicate's products in the United States of America, Canada, Cuba and Porto Rico.
>
> The contract begins with the first of May, 1923, and until then the syndicate will continue the sale and the distribution of its products, through its New York office, which after the first of May, 1923, will be liquidated.

New York Chemical and Allied Markets Are Only Moderately Active

Manufacturers of Salicylates Announce New Advances — Phenol and Derivatives at Higher Levels — Ammonium Nitrate Scarce and Firmer

ALTHOUGH PRICES for most basic commodities were firmly sustained, the chemical market during the past week lacked any outstanding interest. Activity was limited and buyers seemed inclined to purchase only small quantities for immediate consumption. It is possible that the present European trouble will eventually affect the market and some manufacturers were already sitting back to await any helpful changes. Export business to Europe has dropped off considerably, but South American and Far Eastern demand continued along fairly active lines. Producers of salicylic acid announced a new increase of 5c. per lb., because of higher producing costs. Phenol has shown some material gain during the past week and holders were not disposed to offer any round lots. Quotations were considerably higher on all phenol derivatives in sympathy with this product. Ammonium nitrate has become exceedingly scarce on the spot market and traders were asking abnormally high prices for limited stocks. Producers have not been able to offer any material and seem to be heavily sold ahead at the works.

THE ARSENIC MARKET STILL FIRM

Arsenic still remained very scarce on spot and prices were firmly maintained. Lead arsenate and calcium arsenate also retained their former strength. Formaldehyde was somewhat quieter due to the present high prices, although producers seemed quite satisfied with the recent business and stated that a new increase was very probable for the near future, due to the steadily increasing costs of production. Copper sulphate producers have been shipping in fair tonnages to South America, but are somewhat disappointed at the lack of interest from Europe. Domestic consumers have not shown any desire to purchase large stocks, in view of the fact that arsenic and its compounds are so extremely hard to locate. Amyl acetate, ethyl acetate and fusel oil are exceedingly firm and producers are not anxious to book any large tonnages at present levels. Imported caustic potash is materially higher for shipment and on spot. Caustic soda and soda ash continue along moderate lines, with domestic demand covering the lack of interest from exporters.

PRINCIPAL PRICE CHANGES

Alcohol—The market continued along very steady lines and producers reported a well sold up condition at the works. Methanol 95 per cent in barrels is held at $1.21@1.23 per gal., with 97 per cent at $1.23@1.25 per gal. Denatured 188 proof No. 1 formula is moving in a fair way at 39@40c. per gallon.

Arsenic—Leading traders quote this market firm at 15½@16c. per lb. for limited stocks. Several large tonnages were reported on dock from Japan and Germany, but the increasing consuming demand seemed to overbalance these arrivals.

Ammonium nitrate—There has been extreme difficulty experienced in locating spot supplies. Here and there an odd lot was offered at 10@10½c. per lb. Producers are completely sold up at the works.

Amyl acetate—Producers report a steady demand and are finding it difficult to keep pace with deliveries. Supplies on spot are scarce with quotations ranging around $2.80@3 per gallon.

Copper sulphate—Producers report a fair business going into consuming channels, but also state that several orders were cancelled by insecticide manufacturers. Export business was reported fair to South America. Prices range around 6c. per lb. for large crystals.

Caustic soda—Export quotations for standard brands remain around $3.50@3.60 per 100 lb. Domestic material is held at $3.75 per 100 lb. ex-store New York. Contracts for standard material are offered at $2.50 per 100 lb., basis 60 per cent., f.o.b. works, carload quantities. Demand, in general, is merely of a routine nature.

Fusel oil—Spot supplies of crude material are very difficult to locate and producers report a heavily sold up condition at the works. The demand is very strong with quotations ranging around $2.30@2.40 per gal. for crude and $3.50@4.00 per gal. for refined.

Permanganate of potash—Several large sellers have advanced prices of U.S.P. to 16½c. per lb., but the general range is around 16@16½c. per lb. Demand continues fairly active.

Prussiate of potash—There has not been much activity shown in the yellow material of late and prices were held around 38c. per lb. Consumers were not anxious to purchase any round lots at the present high levels. Red prussiate was quoted much lower, with quotations around 85@90c. per pound.

Sal soda—Prices were practically unchanged among leading producers, with barrels ranging around $1.20 per 100 lb. and kegs at $1.35. Demand continues along moderate lines.

Soda ash—Several carload quantities were sold around $1.75 per 100 lb. in bags, on spot. Smaller lots were sold around $2.15@2.35 per 100 lb. Producers offer contracts at $1.20 per 100 lb., f.o.b. works, carload lots, basis 60 per cent, in bags.

Sulphuric acid—Contract business over 1923 is expected to reach very high levels. Withdrawals have already started and producers seem well satisfied with the trend. Spot business, however, is very dormant and quite irregular. Material in tank cars, 66 deg., is held at $14.50@15.00 per ton, with 60 deg. in tank cars at $9.00 a ton.

COAL-TAR PRODUCTS

Benzene—Conditions in this market for the past few months are gradually improving. Prompt shipments are now available to an appreciable degree and sellers have begun to accept new business at 35@40c. per gal. for the pure and 26@30c. for the 90 per cent material. Resale material is still held at a slight premium.

Cresylic acid—The market continued in a very tight position with extreme difficulty experienced among purchasers to locate any nearby shipments. The dark 95 per cent material is quite scarce at 95c. per gal. in drums on spot. Several small sales of 97 per cent goods were recorded as high as $1.25@1.30 per gal. Holders of available material have much firmer ideas and the general tone tends to much higher levels.

Phenol—Prices are materially higher for this material due to the urgent demand from consumers. Producers are heavily sold ahead and spot goods are bringing as high as 36c. per lb. for limited stocks.

Fewer Price Changes in Firm Market at St. Louis

Greater Activity Awaits Completion of Inventory Taking and Better Shipping Conditions

ST. LOUIS, MO., Jan. 11, 1923.

The industrial chemical market of this district since the beginning of the year has not been as lively as expected. It is presumed, however, that this is due to the fact that trade generally is still occupied with inventory matters, but just as soon as this temporary influence has been removed the market will show more activity. Large consumers are showing a more liberal attitude in covering future requirements, which is evidence of better confidence in the market. Freight conditions are somewhat better, but are still below normal. The general tone of the market is very firm and price changes have been few and mostly in the upward direction.

ALKALIS SHOW STRENGTH

Business in alkalis has shown considerable strength since the first of the year and prices are very firm. Some contract business has been reported and a general feeling of confidence seems to exist among buyers. *Caustic soda* is being quoted at $3.90 for solid, $4.30 for flake, $4.50 for the ground per 100 lb. in 1- to 5-drum lots delivered to buyer's door. *Soda ash* is in good demand and quoted at $2.20 in 5-bag lots, and at $2.40 in 5-bbl. lots delivered buyer's door. *Sodium bicarbonate* is holding firm at $2.40 per 100 lb. in 5-bbl. lots, with a good volume of business being transacted. *Sal soda* has slumped some,

and quotations on barreled goods have been reported as low as $1.55 per 100 lb.

GENERAL AND SPECIAL CHEMICALS

The heavy *mineral acid* market is pretty good and fairly firm. Inquiry and demand for *citric acid* is nil and there is only a normal movement in *oxalic acid*. *Tartaric acid* and *cream of tartar* are in very light demand, but that is to be expected at this time of the year. An improvement has been noted in the inquiry and demand for *carbon bisulphide technical*, and some fairly good-sized orders have been placed. There has been no relief for the *white arsenic* situation, as American producers are reporting sold up for some time, and imports have been very small. The future does not seem very promising. Many of the large users have been obliged to curtail their operations because of lack of supplies of this article. The market for *glycerine* is in a rather unsettled condition. No reduction in price has yet appeared except in a few isolated cases where contracts were involved, but it seems to be common knowledge among buyers that glycerine is due for a drop and they are buying in limited quantities in anticipation of a decline. The copperas market has shown no change for some time and is still quoted at $1 in bulk and $1.25 in barrels, f.o.b. mills. There has been no material increase in the production, consequently there has been no accumulation of stocks, and the demand keeping pace with the output. The market has been very firm. *Potassium ferricyanide* and *ferrocyanide* have been moving in appreciable quantities. *Sulphur* is very quiet at present, the demand not being very strong. Prices, however, have not declined. *Zinc dust* is being quoted at 10c. in carload lots, f.o.b. New York, with a very firm market. Spelter has been stationary and a good business reported, which if continued will bring about higher prices. The *zinc sulphate* market has been quiet since our last report. However, it is firm at 3¼c. f.o.b. St. Louis in carload lots.

VEGETABLE OILS AND NAVAL STORES

Castor oil is very firm at 13¼c. in drums, and a good volume of business is being transacted. *Linseed oil* is in a very firm condition and a rise in price is to be looked for. Shipping conditions, a desire on the part of flaxseed producers to hold seed for a better price and the fact that Argentine seed does not affect this market before March 15 at the earliest tend to make for a higher market. *Turpentine* is again on the upward trend and prices today are as follows: 5 bbl. lots, $1.48; single barrels, $1.54 per gal.

PAINT MATERIALS

The paint industry in this section is beginning to boom and orders are being placed that would indicate a prosperous season. There have been no price changes of note, though contracts for material are being placed in some instances for the year's requirements.

A Prediction for the Steel Market

Predictions are always more or less hazardous, but based upon what seems to be in the minds of buyers the prediction might be made that for the next three or four months there will be a very strong market for steel, with heavy deliveries and consumption, and that in the second half of the year there will be relatively light demand. This prediction leaves a leeway of two or three months as a twilight zone. The present showing may as a matter of fact be quite insufficient to base a prediction upon, but there is another factor deserving of consideration, the belief in many quarters that general business conditions, from the long range viewpoint, are hardly sufficient to sustain continuously a movement in steel measured by an ingot production at 40,000,000 tons a year, this being one-third greater than the output in either 1912 or 1913, the two largest tonnage years before the war, likewise one-third greater than the average of 1920, with its heavy output, and 1921, with its very light output. Production in 1922 was about 34,000,000 tons.

Steel Unusually Active Despite Lower Output

December Sales of Sheets More Than 150 Per Cent of Productive Capacity—Other Products Strong

PITTSBURGH, Jan. 12, 1923.

The 30 companies which make monthly returns of their steel ingot output report a production of 2,779,890 tons in December against 2,889,297 tons in November. The decrease is barely as much as the decrease in the number of working days from 26 to 25, while a little output was no doubt lost through the holiday season. Order books are in better shape than 30 days ago, labor supply is somewhat better than in October, simply on account of the curtailment in outdoor work, and pig iron and fuel supplies are sufficient for a heavier production.

Production of ingots by the steel industry as a whole was at a rate of about 40,000,000 tons a year in each of the last three months, there being no noticeable variation from month to month, and the prospect is that production will be somewhat heavier this month. The quarter as a whole may show a gain of 5 to 10 per cent over last quarter. No large increase could be expected, on account of labor supply, whatever the other factors in production might be.

All the finished steel markets are more or less active, the most sluggish item being structural shapes. In plates the activity is moderate except in car plates, which are booked far ahead.

SHEET MILLS DOUBLE THEIR SALES

The majority of independent steel producers had heavy bookings in December. Some of the independents entered December with decidedly lean order books, scarcely sufficient to carry some departments through the month, and these independents are now much better fixed. The independent sheet mills that report to the National Association of Sheet and Tin Plate Manufacturers, representing 66.5 per cent of the total capacity of the sheet industry, reported sales for December of 399,624 net tons, or 156.6 per cent of a month's capacity, almost double the business reported for any one of the preceding five months.

On the other hand, the United States Steel Corporation reported a December decrease in unfilled obligations of 94,539 tons, against a November decrease of 62,045 tons, and this despite the fact that its sheet and tin plate subsidiary opened its order books for the new period only on November 23, thus being a very light seller in November and a heavy seller in December.

Nearly all the independent wire mills have advanced their prices $2 a ton or more. The Steel Corporation seems unlikely to advance its prices on wire or other products. The greatly improved order books of independent sheet mills make relatively safe a prediction that the independent sheet mills will soon begin advancing their prices quite generally. The Wheeling pipe independent, previously one point above the general level, recently advanced another point. Nails are quotable at $2.70 to $2.80 and plain wire at 2.45c. to 2.70c.

Bars, shapes and plates are now very strong at the 2.00c. level, which was being shaded more or less in November. Hoops are 2.75c. to 2.90c., depending on gage, etc. Recently some attractive orders were booked at as low as 2.50c.

Billets, slabs and sheet bars are all quotable at $37.50 to $38.50, against a general level of $36.50 lately ruling, at which much first quarter contract tonnage was entered. There have been sales at both $37.50 and $38.50 in the past week. The $45 rod price has entirely disappeared, leaving the market at $47.50 for good orders and up to $50 for single carloads.

COKE AND PIG IRON

Connellsville coke has softened somewhat in the week, furnace coke being now easy at $8.50, with foundry at $9 to $9.25. The market is, however, much above the level existing when the sudden demand from the east for domestic coke effected a sharp advance. Furnaces seem to be well covered by contracts at $7.00 to $7.50. Production has been increasing, car supplies being materially better.

Pig iron has been dull as to actual turnover, but prices are stiffening. On small prompt lots of foundry iron valley furnaces are securing $28, furnace, against a general quotation of $27 a week ago, while first quarter contracts were made at $25 in the buying movement of about 30 days ago. Basic iron is not clearly defined. Recent transactions were at $24.25 and $24.50, valley, and since then there have been one or two sales on a basis of $25.50 or $26, but it remains to be seen whether such prices can be obtained generally. In some quarters the claim is made that basic iron cannot be bought at under $27. Bessemer remains at $27.50, with occasional small transactions.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Mercury	75 lb.	74.00

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	20.00
Copper bottoms	30.00
Copper rods	19.75
High brass wire	18.75
High brass rods	16.75
Low brass wire	19.60
Low brass rods	20.25
Brazed brass tubing	23.00
Brazed bronze tubing	28.00
Seamless copper tubing	24.75
Seamless high brass tubing	22.00

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

Copper, heavy and crucible	11 00@11.25
Copper, heavy and wire	10.50@10.75
Copper, light and bottoms	8.50@8.75
Lead, heavy	4.50@4.75
Lead, tea	3.25@3.50
Brass, heavy	5.50@5.75
Brass, light	5.00@5.25
No. 1 yellow brass turnings	5.50@5.75
Zinc	2.25@2.50

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$2.90	$2.90
Soft steel bars	2.80	2.80
Soft steel bar shapes	2.80	2.80
Soft steel bands	3.40	3.40
Plates ¼ to 1 in. thick	2.90	2.90

Industrial

Financial. Construction and Manufacturers' News

Construction and Operation

Alabama

EMPIRE—The Empire Coal Co Birmingham, has plans nearing completion for the construction of a byproduct coke plant at its properties near Empire, to consist of an initial battery of 40 ovens and auxiliary equipment. The project is estimated to cost close to $1,000,000.

TARRANT CITY—The National Cast Iron Pipe Co. has broken ground for the erection of a large addition at its local foundry, and will also make a number of improvements in the present works. The De Lavaud process of cast iron pipe production will be installed in the new plant A fund of more than $200,000 has been arranged for the expansion

Arkansas

CAMDEN—The Texas Co, Dallas, Tex, has commenced the construction of a new oil storage and distributing plant at Louann near Camden, with initial installation to comprise twenty-five 55,000 bbl tanks and auxiliary equipment

SMACKOVER—The Pan-American Petroleum & Transport Co, 120 Broadway, New York, has acquired a tract of local property, consisting of about 165 acres, and plans for extensive development Plans are under way for a storage and distributing plant of twenty-two 66,000 bbl tanks and auxiliary apparatus Edward L Doheny is president

PEARSON—The Lion Oil & Refining Co Kansas City Mo, will soon commence work on a local oil plant to consist of six 1,000 bbl. stills, 9 steel tanks and other operating equipment. It will cost in excess of $75,000

California

FRESNO—The California Products Co Butler and O Sts, Robert Hulme, head has preliminary plans under consideration for the establishment of a local plant for the manufacture of industrial alcohol and kindred specialties.

LOS ANGELES—The Minarock Products Co. is completing plans for the installation of a new crushing and screening plant, for the production of special rock and mineral products, to include complete rock crusher, grade screens, storage bins and conveying equipment. A. Godfrey Bailey, Jr, 110 Orpheum Bldg, is architect

Connecticut

NORWICH—The Uncas Paperboard Co, recently organized with a capital of $1,500,000, is planning for early operations at the local plant of the Ironsides Board Corp. recently acquired at a receiver's sale by James E. Smith of the Chesapeake Paper Board Co., Woodall St., Baltimore, Md, and who will head the new organization It is purposed to remodel a number of buildings at the mill, and install additional equipment. Others interested in the new company are Frank W Browning and Joseph H Eilers, both of Montville, Conn

Georgia

ATHENS—The George Brick Co has arranged a list of equipment for installation at its new local plant, to replace the works recently destroyed by fire and will commence rebuilding at an early date It is proposed to develop a capacity of 30,000 bricks per day H H. Hinton and R C Wilson head the company.

SAVANNAH—The Georgia-Florida Fertiliser Co. has perfected plans for immediate operations at the former plant of the Kirkland Fertilizer Co, near Savannah, recently acquired. A number of improvements will be made for increased production.

Illinois

TAYLORVILLE—The Hopper Paper Co recently organized, has revised plans under way for the construction of its proposed new mill, to be 2-story and basement, 80x165 ft, estimated to cost approximately $75,000 E. Hopper, president of the Kalamazoo Sanitary Mfg Co, Kalamazoo, Mich., heads the new organization Billingham & Cobb, Press Bldg, Kalamazoo, are architects

Indiana

SEYMOUR—The Silverstone Stucco & Plaster Products Co., 3323 Park Ave, Indianapolis, John R Briggs, president, recently incorporated, is planning for the construction of a new local plant for the manufacture of stucco under a new process, plaster and lime products, etc It is estimated to cost about $100,000 including machinery

Kansas

BONNER SPRINGS—The International Cement Corp, 342 Madison Ave, New York, has acquired the local plant of the Bonner Portland Cement Co., for a consideration said to be about $600,000 Plans are in progress for extensions in the present works including the installation of considerable new equipment for increased manufacture It is expected to develop a maximum output of close to 600,000 bbl. per annum Holger Struckman is president

Kentucky

LAWTON—The Enterprise Chemical Co, P O Box 545, Huntington, W Va, recently formed with a capital of $100,000, has plans under way for the erection of a local plant for the manufacture of lime products, to include crushing, pulverizing, screening and other operating departments. A hydrating plant is also contemplated It is expected to develop an output of 1,500 tons per day F L Parr is general manager, and William Lewis construction engineer.

Maryland

BALTIMORE—The United States Industrial Alcohol Co, 27 William St., New York, is contemplating plans and will take bids in the near future for the erection of a new 1-story addition to its local plant in the Curtis Bay district, 60x180 ft Samuel Moore is company engineer

BALTIMORE—The Board of Directors, Johns Hopkins University, has plans nearing completion for the erection of a new chemical laboratory at the institution, estimated to cost approximately $600,000, with equipment It is expected that bids will be called for at an early date. Edward L Palmer, Jr, 513 North Charles St, is architect

HAVRE DE GRACE—William E Veasey, Havre de Grace, is perfecting plans for the organization of a company to construct and operate a local plant for the manufacture of brick, tile and other burned clay products A list of equipment to be installed will soon be prepared.

BALTIMORE—Fire, Jan 5, destroyed the plant of the Commercial Envelope Co., 2400 Frederick Ave., manufacture of paper products, with loss approximating $50,000, including equipment It is expected that the plant will be rebuilt Howard Jones heads the company

Massachusetts

BOSTON—Henry Gibbons, 12-20 Glenwood Ave has filed plans for the erection of a new 1-story foundry

CLINTON—The Clinton Gas Light Co, Pleasant St, has plans under way for the construction of a 2-story addition to its artificial gas plant on Parker St, to cost about $125,000. W. W Russell, 77 Franklin St., Boston, is engineer

Michigan

MONROE—The River Raisin Paper Co. has tentative plans under consideration for the erection of a 1-story addition to its plant, to be used primarily for the manufacture of box-board and other carboard products. G H. Wood is president.

IRON MOUNTAIN—The Ford Motor Co., Highland Park, is considering plans for the construction of a new local plant for the manufacture of chemical products including wood alcohol, acetate of lime and other byproducts. The size and estimated cost are being determined.

LUDINGTON—The Marine Rubber Corp, recently organized under Delaware laws with capital of $1,250,000, will succeed the Ludington Rubber Co., taking over and operating a local plant for the manufacture of a line of rubber products for marine and other service Extensions and improvements are planned. A. H. Gruber is president, and Andrew W Newberg, vice-president.

Nevada

TONOPAH—The Tonopah Extension Co. has plans in progress for extensions in its local mill, including the installation of additional equipment to increase the output from 415 to 500 tons per day

New Jersey

NEWARK—The Armitage Varnish Co, 189-215 South St, has perfected plans for the immediate erection of a 3-story plant, 18x50 ft., estimated to cost about $25,000

RIDGEFIELD PARK—The Bogota Folding Box Co., Bogota, N J, has acquired the plant of the British American Chemical Co., Ridgefield Park consisting of a number of buildings totaling 55,000 sq ft, on a 7-acre tract of land for a consideration of $80,000 The selling company, represented by a receiver, is now defunct The purchaser is said to be planning to use the property for a new plant Herman M Hess and Michael Densen head the company

New York

BROOKLYN—Gerstendorfer Brothers, 231 East 42d St, New York, manufacturers of bronze powders, etc, are having plans completed for the erection of a new 7-story plant at Clinton and Bush Sts, estimated to cost $350,000 Russell G Cory, 30 Church St, New York, is consulting engineer

LONG ISLAND CITY—The Oscar Schlegel Mfg. Co., 124 East 13th St, New York manufacturer of paints, varnishes, etc, has leased a building now in course of erection at the northwest corner of Harris Ave and the Boulevard for the establishment of a new plant The Martini Artists' Color Laboratories, same address, manufacturer of artists' paints and colors, has leased property at the same location, Long Island City, for a new works.

SYRACUSE—Fire, Jan 3, destroyed a portion of the tanning plant of the Onondaga Hide & Leather Co, East Water St., with loss estimated at about $15,000, including equipment It is planned to rebuild

Ohio

CINCINNATI—The Kemper-Thomas Co, Park Ave, near Floral Ave., Norwood, manufacturer of paper products, will take bids at once for the erection of a new 3-story and basement addition, 60x220 ft, to cost about $150,000, including equipment Samuel Hannaford & Sons, 1024 Dixie Terminal Bldg., Cincinnati, are architects.

ZANESVILLE—Fire, Dec 21, destroyed the enamel department and other portions of the plant of the Mark Mfg Co, manufacturer of steel conduit, pipe, tubing etc., with loss estimated at close to $400,000, including equipment It is planned to rebuild. The company is a branch of the Steel & Tube Co. of America, Inc., 111 West Washington St., Chicago, Ill.

CAMBRIDGE—E. M. Darner, Zanesville, has acquired the local plant of the Guernsey Earthenware Co, at a receiver's sale, for a stated consideration of $80,500 The new owner is said to be planning to operate the pottery.

MIDDLETOWN—Z W. Ranck and W. H Muchmore, Shelby, O., have organized a new company to take over the property of the Shelby Wax Paper Co., Shelby. The equipment at the plant will be removed to the works of the Central Tissue Co., Middletown, wax paper department, which will be developed for large increase in capacity. Mr. Ranck will be president of the new company, and Mr Muchmore, vice-president and general manager.

Oklahoma

RINGLING—The Gilmer Oil Co Ardmore, Okla., has acquired a local refinery and has plans under way for extensions and improvements in the plant.

TULSA—J. J. Kerins, Tulsa, is perfecting plans for the organization of a company to construct and operate a new oil refining plant in the Tonkawa district. The initial plant will have a capacity of about 2,000 bbl. per day.

TULSA—The Producers' & Refiners' Corp., California Bldg. Denver, Colo., operating

local oil refineries, is completing arrangements for the purchase of the refining plants and properties of the Barnsdall Corp., the Texas-Pacific Coal & Oil Co., and the Fensland Oil Co., representing total assets of about $125,000,000, with plants in the Mid-Continent, Texas and Wyoming fields. The new owner plans for extensions and improvements for extensive increase in production.

MUSKOGEE—The Sinclair Refining Co. has perfected plans for the removal of its oil refinery at Vinita, Okla., to the refining plant at Muskogee, where the consolidation will be developed for considerable increase in production.

Oregon

ASTORIA—The Astoria Shope Brick Co has acquired a local site for the erection of a new plant with initial output of about 35,000 bricks per day, and will break ground at an early date. A list of machinery to be installed is being arranged. The company has recently been organized with a capital of $250,000.

PORTLAND—The Portland Oxygen & Hydrogen Co, Center and East 17th Sts, has awarded a contract to the Hurley-Mason Co., Gasco Bldg., for the erection of a 1-story addition to its plant.

Pennsylvania

ZELIENOPLE—The Common Council is having plans prepared for the installation of a filtration plant at the municipal waterworks to cost about $35,000. Leo Hudson, Wabash Bldg., Pittsburgh, is engineer.

HAYSVILLE—Fire, Jan. 3, destroyed a portion of the plant of the Sterling Varnish Co., including two buildings, with loss estimated in excess of $50,000, including equipment. Headquarters of the company are in Fulton Bldg., Pittsburgh. James Todd is president.

POTTSVILLE—The Common Council has ordered a sanitary survey of the city, preparatory to the installation of a new sewage filtration plant, estimated to cost in excess of $500,000, with equipment, for which plans will be authorized in the near future.

PHILADELPHIA—S. Kardan, 2d and Vine Sts., manufacturer of paper products, has plans under way for the erection of a new 5- to 8-story plant at South, Swanson and Bainbridge Sts., estimated to cost about $500,000 Clarence E. Wunder, 1415 Locust St., is architect.

FARMERS VALLEY—A new company has been formed by Warren, Pa., interests for the construction and operation of a local oil refining plant, on site owned by the B. B. Stroud Gasoline Co., Coleville, near Farmers Valley, which is interested in the project.

South Carolina

PREGNALL—The Atlantic Turpentine Co., St. George, S. C., recently organized, has acquired local property and plans for the early erection of a new plant for extensive production. H. H. Gross is president, M S Connor, secretary and treasurer, and T A Patrick, general manager, the last two officials being located at St. George.

Texas

ELECTRA—The Griswold Oil Co., Henrietta, Tex., has completed arrangements with the Electra Chamber of Commerce and Agriculture, for the acquisition of a local site for the erection of a new oil refinery, estimated to cost close to $500,000. The present refining plant at Henrietta will be removed to the new location, with the installation of additional equipment for extensive increase in output, including 2 new cracking plants, and new casinghead gasoline works. The company has also secured the local property of J. F Emerich in the South Electra field.

HOSKINS MOUND—The Freeport Sulphur Co., Freeport, Tex., has active construction in progress on its new local sulphur plant, estimated to cost in excess of $1,500,000. The works will include a large power house and a chemical-treatment water plant to handle approximately 3,500,000 gal per day. It is expected to have the plant ready for operation early in the spring. C. M. Chapman is consulting engineer for the company.

SAN ANGELO—The San Angelo Water, Light & Power Co. is planning for the installation of a filtration plant at its local waterworks. The company is operated by the Interstate Electric Corp., 141 Broadway, New York. M. F. Treadwell is local manager at San Angelo.

Washington

VANCOUVER—The Columbia River Paper Mills, Inc., operated by the California-Oregon Paper Mills Co., East 57th St., Los Angeles, Cal., is perfecting plans for the erection of a new local plant. The city council is vacating a number of streets for the mills.

West Virginia

WHEELING—The Wheeling Steel Corp. has commenced the construction of a new sintering plant at its East Steubenville works, and plans to rush the structure to completion. Special furnaces will be installed to utilize the flue dust from the blast furnaces, converting it into a solid for iron manufacture.

Wisconsin

KENOSHA—The Frost Mfg. Co., Fremont St., manufacturer of brass castings, is considering plans for the construction of a new 1-story foundry W. J. Frost is president.

Canada

WINNIPEG, MAN—The Swift-Canadian Co., operated by Swift & Co., Union Stock Yards, Chicago, Ill., plans for the rebuilding of its Elmwood fertilizer plant, partly destroyed by fire, Dec 22, with loss estimated at $35,000.

British Columbia

VICTORIA—D. D. McPhail, Kelso, Wash., and associates, are organizing a new company to construct and operate a large pulp and paper mill in the vicinity of Nitinat Lake. The initial plant unit is estimated to cost in excess of $500,000, and will be supplemented with other units at a later date, making an ultimate cost of more than $1,500,000.

Industrial Developments

LEATHER—The Carr Leather Co, Peabody, Mass, is running at full capacity with regular working force, and is said to have orders on hand to insure continuance on this basis for a number of months to come.

Glazed kid manufacturing plants at Camden, N J, Philadelphia, Pa, and Wilmington, Del, are maintaining full operations with full working forces and propose to continue on this basis for an indefinite period.

The A. C. Lawrence Leather Co, Peabody, Mass, has resumed production at its local pig skin tannery, which has been practically idle for close to 2 years past. Initial operations will be on a curtailed capacity basis for the time being.

The Essex Tanning Co, Peabody, Mass., is running under heavy output at its plant, and has orders on hand to insure this basis for some time to come. A full working force is being employed.

GLASS—The Owens Bottle Co, Clarksburg, W Va, has placed an additional unit in operation at its plant bringing production to a capacity basis, or 3 000 gross boxes of bottles per day. The plant will continue on this schedule for an indefinite period, giving employed to approximately 200 workers.

Glass factories in the vicinity of Paulsboro, N. J., are advancing operations and expect to give employment to an increased number of workers at the season matures. It is said that 1923 will be the busiest year since 1919.

Following a brief curtailment for inventory, the Indiana Glass Co, Dunkirk, Ind, has resumed production on a capacity basis and is said to have orders on hand to insure this schedule for a number of months to come.

Window glass manufacturers represented in the National Association of Window Glass Manufacturers have granted a wage increase of 13 per cent at all hand plants throughout the country, effective Jan. 29 and concluding June 11.

CERAMIC—The American Clay Products Co, New Hope, Pa, is perfecting arrangements for the opening of its local plant late in February. The works have been in course of erection since the spring of 1920, and are said to represent an investment of more than $1,000,000. The plant will specialize in the manufacture of shale brick and will develop an ultimate output of about 500,000 bricks per day.

The Carpenteria Clay Products Co., Carpenteria, Cal., has commenced operations at its new local plant, recently completed, and will concentrate on the manufacture of brick and hollow tile.

The Champion Spark Plug Co., Toledo, O., is advancing capacity at its plant and is now running on the basis of 120,000 spark plugs each working day.

The Bethlehem Spark Plug Co., Bethlehem, Pa., is running on a capacity basis and expects to continue this schedule for an indefinite period. An order has been secured from the International Harvester Co. for 1923 spark plugs, said to total $500,000; a large order has also been received from the Packard Motor Car Co.

The National Drain Tile Co., Summitville, near Anderson, Ind., has closed its local plant for an indefinite period.

The Thress Brick Co., Tuscaloosa, Ala., is planning for increased production at its plant.

RUBBER—The Goodyear Tire & Rubber Co., Akron, O., has resumed full production at its local plant following a short curtailment for inventory.

The Hood Rubber Co., Watertown, Mass., is maintaining full capacity at its mill and will continue on this basis for an indefinite period. A new record output has been established.

IRON AND STEEL—The American Sheet & Tin Plate Co. has resumed operations at its La Belle Works, Wheeling, W. Va., with a full working force, after a shut down for the past 6 months.

The Conners Steel Co, Birmingham, Ala., has resumed operations on a capacity basis at its hoop and band mills.

The Standard Tin Plate Co, Canonsburg, Pa., has resumed operations at 8 hot mills, suspended on account of necessary repair work a few months ago, making a complete battery of 24 mills in service on full turn. The plant is giving employment to about 2,500 men.

The Delaware River Steel Co. has arranged for the blowing in of its blast furnace at Chester, Pa, on foundry iron. A normal working force will be employed.

The Hall blast furnace, Sharon, Pa., will be dismantled. The unit has been inactive for a number of years past. A portion of the equipment will be utilized at a plant at Youngstown, O.

A total of 24 blast furnaces are now in operation in Alabama, the largest number in service at one time for the past 2 years. Production is being concentrated on pig iron, with full time working forces. Ten of the furnaces are owned by the Tennessee Coal, Iron & Railroad Co., 5 by the Sloss-Sheffield Coal & Iron Co.; 4 by the Woodward Iron Co.; 2 by the Republic Iron & Steel Co., and one furnace each by the Gulf States Steel Corp., the Alabama Co., and the Central Iron & Coal Co.

The McCullough Iron Works, Wilmington, Del, has been sold and the plant will be dismantled.

The United States Steel Corp., is maintaining 100 per cent capacity operations at its mills in the Youngstown, O., district.

MISCELLANEOUS—The National Sulphur Co, North Akron, O., has arranged for immediate operations at its new local plant, recently completed.

The Pyrites Co, Ltd, Roanoke, Va., has repairs in progress at its local plant and plans to resume production at an early date. The plant has been closed for about 18 months past.

The United States Graphite Co., Saginaw, Mich., is arranging for the immediate resumption of operations at its La Colorado properties at Torres, Mex.

The Morse Blacking Co., Peabody, Mass., manufacturer of shoe polishes and kindred products, is running on a capacity basis, with sufficient orders on hand to maintain this schedule for some time to come.

Four out of 8 oil refineries in the Ardmore, Okla., district are on the producing list, these being the Cameron Refining Co., operating at 2,000 bbl. per day, with capacity rating of 3,000 bbl.; the Pure Oil Refining Co., on a 2,700 bbl., daily output, and capacity rating of 7,000 bbl.; the Imperial Refining Co., on a basis of 4,000 bbl., with maximum plant capacity of 5,000 bbl.; and the Nyanza Refining Co., 1,500 bbl., daily production, with rated capacity of 3,500 bbl.

Employees at the refining plant of the Standard Oil Co., Bayonne, N. J., have submitted a petition to the company asking a general wage increase.

The Fort William Pulp & Paper Co., Ottawa, Can., is arranging to increase production at its mills to an average of 150 tons of newsprint per day.

The Anaconda Copper Co., 25 Broadway, New York, is planning to inaugurate operations at the first unit of its new zinc oxide plant at East Akron, O., now nearing completion, early in February.

The American Cotton Oil Co. has closed 6 mills in Georgia and 2 mills in South Carolina for an indefinite period. It is said that some of the plants will be abandoned. Divisional headquarters have been moved from Atlanta, Ga., to Memphis, Tenn.

Capital Increases, etc.

THE CENTRAL MICHIGAN PAPER CO., Grand Rapids, Mich., has filed notice of increase in capital from $25,000 to $300,000 for proposed general expansion.

THE NASSAU SMELTING & REFINING WORKS, INC., 603 West 29th St., New York, N. Y., has arranged for an increase in capital from $1,000,000 to $1,500,000.

THE LOUISVILLE PAPER CO., Louisville, Ky., has filed notice of increase in capital to $750,000 for proposed expansion.

THE GILL CLAY POT CO., Muncie, Ind., has filed notice of increase in capital from $100,000 to $200,000 for expansion.

THE TEXAS PORTLAND CEMENT CO., Dallas, Tex., has arranged for an increase in capital from $1,000,000 to $2,000,000 for proposed expansion.

THE THOMAS MADDOCK'S SONS CO., Trenton, N. J., manufacturer of sanitary ware, has filed notice of increase in capital from $600,000 to $1,135,000.

THE SWIGART PAPER CO., 653 South Wells St., Chicago, Ill., has arranged for an increase in capital from $750,000 to $950,000.

THE CHARLES H. PHILLIPS CHEMICAL CO., Stamford, Conn., has arranged for an increase in capital from $50,000 to $150,000 for expansion.

New Publications

BOOKS

IRON ORE (Summary of Information as to the Present and Prospective Iron-Ore Supplies of the World), Part 7, Foreign America. H. M. Stationery Office, London. 136 pp., 3 maps. Price, 4s. 1½d.

A comprehensive economic survey is made of the iron ore resources of the United States, Cuba and the West Indies, Mexico and Central and South America. Particular attention is given to the geological aspects of this question, to the economic position of the various competing districts and to the statistics of production and trade.

A FIRST BOOK OF CHEMISTRY. By A. *Coulthard*. Technical Research Chemist with the British Dyestuffs Corporation Ltd. Published by Pitman & Sons, London. 136 pages, 3 maps. Price, 4s. 4½d.

This is a rather unusual little book designed as a text for students in a junior technical school where a year's work devoting 3 to 4 hours a week to chemistry is undertaken. The author, probably because of his long teaching experience, has admirably succeeded in projecting himself to the beginner's viewpoint, with the result that he has produced a textbook of unusual value.

TESTING METHODS OF METALLURGICAL ANALYSIS (NON FERROUS). By *Seymour Pile* and *Reginald Johnston*, with a prefatory note by *C. T. Haycock*. Published by H. F. & G. Witherby, London. Price, 7s. 6d. net.

The authors have attempted to sort out from the extensive literature on non-ferrous chemical analysis those methods which appeared most practical for ordinary usage. These were thoroughly tested and attention was given to the various manipulative details so often necessary for the success of the particular method. The book is "intended to be to the analyst what a set of working drawings are to the mechanic."

COMMERCIAL TRAVELER'S GUIDE TO LATIN AMERICA, U. S. Department of Commerce, Miscellaneous Series No. 89, Superintendent of Documents, Government Printing Office, Washington, D. C. Price, $1.25.

Everything that the commercial traveler should know about the twenty republics and many colonies to the south of us, in order to make a profitable and enjoyable business trip, is encompassed in 734 pages. It is compiled by Ernest B. Filsinger, assisted by corps of experts of the Department of Commerce. Steamship lines and railroads, time tables and connections, road routes, hotels and rates, taxes on travelers and restrictions, duties on samples and advertising matter, nothing essential is omitted. "The traveler is told about the banks, postal service and postal rates, weights and measures, and all things that may obviate those vexatious delays which are especially troublesome to the uninformed and inexperienced traveler in Latin America. Every city and market of importance in the Latin Americas is listed with informtaion as to its characteristics, trade regulations, license fees, routes by which to reach it, etc., and the traveler is given abundant sound advice to be followed in canvassing each section.

Industrial Notes

THE PITTSBURGH-DES MOINES STEEL CO., Pittsburgh, Pa., announces that from Jan. 1, 1923, Joseph S. Harrison is made advertising manager of the company. J. A. Bickelhaupt, the former advertising manager, moves temporarily to Richmond, Va., and opens a sales and construction office for the company. The Richmond office will handle the entire southeast territory from Baltimore on the north and Birmingham on the west.

THE INDUSTRIAL BUREAU OF THE CHAMBER OF COMMERCE, 32 Court St., Brooklyn, N. Y., has issued a map showing graphically the vast industries of Brooklyn. Eleven of the main industries are shown by bar made on a percentage basis.

THE PRECISION INSTRUMENT CO., of Newark, N. J., and Detroit, Mich., announces that Alfred B. Carhart has resigned his position as vice-president and sales manager of the Crosby Steam Gage & Valve Co. to become president and general manager of the Precision Instrument Co., Inc., which has acquired control of the Precision Instrument Co. The present executive officers will retain their connection with the company. It is expected to enlarge the business considerably, with new capital, adding specialties, also staple lines of gages, valves and fittings. Mr. Carhart assumes his duties at once and will be located at the New York office at 114 Liberty St. The factory will later be moved to New York.

THE INGERSOLL-RAND CO. and the A. S. CAMERON STEAM PUMP WORKS announce the opening of a branch office at 718 Ellicott Square Bldg., Buffalo, N. Y.

HOWARD E. EDDY, formerly identified with Manning, Maxwell & Moore, Inc., of New York, has become vice-president and general manager of the Nelson Valve Co., Philadelphia, Pa. C. W. Brown, of Philadelphia is secretary and treasurer. C. D. Miller, formerly identified with the Bridgeport Works of Manning, Maxwell & Moore, Inc., is works manager, and C. W. Burrage of the same company mechanical engineer.

THE FRASSE STEEL WORKS, INC., Hartford, Conn., has been appointed the exclusive New England distributor for the Sizer Steel Corp., with plants at Buffalo and Solvay (Syracuse). The company manufactures electric carbon, alloy and tool steels, bars, billets and forging and die blocks.

THE PETROLEM IRON WORKS CO., Sharon, Pa., announces that its Denver office in the First National Bank Bldg., has been discontinued. T. J. Mullin, formerly the Denver representative, is now located in the St. Louis office in the Central National Bank Bldg. A new office to serve the Western territory has been opened in Casper, Wyo., at 407 Oil Exchange Bldg., in charge of H. S. Dilcher.

THE CARPENTER STEEL CO., of Reading, Pa., announces that statements in newspapers and elsewhere reporting the merger of the company with some other steel concern or its sale to other interests, are entirely erroneous.

H. H. REPLOGLE has resigned as manager of the intermediates and certified food color divisions of the National Aniline & Chemical Co. to assume the sales management of the Wamesit Chemical Co., Lowell, Mass., domestic manufacturer of lactic acid, lactates, lactart and lactic acid compounds.

THE NATIONAL TUBE CO., of Pittsburgh, Pa., has announced the establishment of an industrial fellowship in the Mellon Institute of Industrial Research of the University of Pittsburgh, Pa. This fellowship is engaged in a systematic study of practical methods for the prevention of corrosion in hot-water supply systems. It is also giving attention to the classification of waters of various chemical composition, with respect to their relative corrosive action upon iron and steel, particularly in the form of pipe lines, boiler-economizers, tubes, etc. The present incumbent of the fellowship is Clifford R. Texter, who for the past several years has been carrying out research on the corrosion of iron and steel where not exposed directly to the atmosphere. Mr. Texter will be glad to correspond with engineers and manufacturers interested in the field to which his fellowship relates.

THE WILSON WELDER & METALS CO., New York, is now represented exclusively in Maryland, Virginia and the District of Columbia by the Alexander Milburn Co., of Baltimore. A large stock of color-tipt welding metals and plastic-arc welding machines is available at this point for distribution throughout the territory and a complete demonstration plant in operation.

George Macnoe, manager of the Boston office of W. B. CONNOR, INC., has been recalled to New York to take charge of the contractors' sales department, handling heating and pumping equipment.

THE RUBBER ASSOCIATION OF AMERICA, INC., announces the removal of its office to 250 West 57th St., New York City.

William T. Hand has severed his connection with the TECHNICAL PRODUCTS CO., INC., and has organized the William T. Hand Equipment Co. at 2709 Grand Central Terminal, N. Y., which will specialize in new and used chemical process equipment.

THE LINDE AIR PRODUCTS CO. has obtained a site in St. Louis and North Anthony Sts., New Orleans, for a large branch factory for the production of hydrogen and oxygen and their products. The first unit of the plant is but a small part of the ultimate plant representing an investment of $130,000.

The Ashburn plant of E. I. DU PONT DE NEMOURS & CO. has lately been put in operation after having been closed for a year. M. C. Knabe has been appointed manager and P. C. Kaiser is assistant manager. The technical staff is composed of the following men: F. E. Jacquot, superintendent of powder lines, P. S. Cushing is superintendent of acid manufacture and G. A. Beane is superintendent of power.

THE PRECISION INSTRUMENT CO., Newark, N. J., and Detroit, Mich., is offering to the trade a new CO_2 recorder. This recorder will embody all the good features of the present Precision CO_2 recorder, but is an innovation in that it will remove CO_2 recorders from the present laboratory types to the boiler room equipment. The salient features are: Motor drive of the G.E. type, constant speed, direct drive, no belts; positive in action, elimination of water or steam troubles, no glass parts; simplicity of design and operation; accurate in results and powerful enough to overcome any boiler suction.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodose Hotel New York 1923, at the Commodore Hotel, New York.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 8 and 9, 1923.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society joint meeting. March 9 American Chemical Society, Nichols Medal. March 23 Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

A consolidation of
ELECTROCHEMICAL & METALLURGICAL INDUSTRY *and* IRON & STEEL MAGAZINE

Volume 28 New York, January 24, 1923 Number 4

The Future of the Federated Societies

NEWLYWEDS are usually admonished that the second year of married life is the hardest—or perhaps it is the third—and that the first year of nuptial bliss will be no criterion of the permanence of their relations. It is after the glow of the honeymoon has faded and the bright light of a workaday sun has revealed the stern realities of the job that the danger of wreck or disaster impends. Somehow it is not easy to foresee, to project themselves into the future. Imagination is inadequate and realization comes with somewhat of a shock. In the crisis they either quit the game, disillusioned, or readjust and adapt themselves to life as they find it.

But it is not in domestic relations alone that the experience holds true. It is a factor in all human relations, whether for social, business or professional purposes. The first year is one of hope and expectation, ambition and determination; the second and third years bring the test of stability and permanence. And so it is that Federated American Engineering Societies having been launched in a spirit of public service and having given a fair account of itself for a couple of years, finds itself facing the critical period of its existence.

In our judgment the crisis is largely psychological and arises either from a failure to appreciate the aims and purposes of the Federated or a tendency to expect and demand too much of it. In the first place the Federated was organized "to further the public welfare wherever technical knowledge and engineering experience are involved," to make the voice of engineers as a group articulate in public affairs. Hence there is no personal gain to be derived from membership in the Federated. It is not a question of what a member may get out of it, but what he is willing to put into it. It exists as a medium through which engineers may be of service to the public, not themselves. It is a case of giving, not receiving; and the measure of success of the organization is what it has done for the public welfare.

In the second place much of the work of the Federated is not spectacular nor does it appear with the regularity of daily, weekly or monthly routine. Hence, although the organization must justify its existence by its works, it can act only or mainly when there is a call for its services. It will not constantly have opportunities to look into industrial waste or study Muscle Shoals or make an investigation of the 12-hour shift. But it is there for just such purposes when the problems arise and can be financed—and that existence is an accomplishment in itself.

As we see the Federated, it is something to be perpetuated if engineers are to have a medium of expression on public matters when occasion arises. It can help fulfill its destiny if it will adopt machinery to make the voice of the engineer articulate in public affairs by conducting referendums much after the manner of the Chamber of Commerce of the United States. Further, it must face its problems with courage and avoid the soft pedal in its work. And it must conduct its overhead and administrative affairs in the utmost economy, putting financial emphasis on productive work. Its membership, on the other hand, must continue unstinted support and not be too exacting in demands for productive activity. By all means let us continue the Federated and support it through this trying third year. Once the crisis is past and the organization has found itself it will justify its existence, not only among engineers but in the mind of the public for which it was organized. In the meantime let's get some action on that Muscle Shoals investigation, and look about to see what local industrial surveys can be made in medium-sized cities. If the engineers will investigate and supply the data, industrial and commercial leaders can be depended upon to translate them into action.

The Dangers of One Big Company

AT A DINNER of Group 8 of the New York State Bankers Association on Jan. 15 CHARLES M. SCHWAB said that in the 43 years he had been engaged in American industries, steel production had increased from 800,000 to 50,000,000 tons a year. "The greatest economy that can come to this country," he is reported as adding, "is manufacturing in as large quantities as possible and cutting the overhead. To have every steel works in one big company would be good economically."

Mr. SCHWAB is a man of rare illumination and supreme ability. Usually we agree with him. But suppose such a super-organization were legally possible and practically feasible, who is there besides Mr. SCHWAB himself or Judge GARY with the ability to direct its affairs? The wrong man at the head means failure in part or in whole. But let's imagine the One Great Company established and the right man at the head. Although Mr. SCHWAB is a hearty, very human speaker, he measures his words. He said it would be a good thing economically, and we agree that the costs of steel would probably come down in some measure. But we doubt if it would be a good thing in any other respect, or even economically in the long run.

How much the steel would sell for to consumers would depend in part on how much water the promoting bankers would pump into the new securities. If this were to absorb the economies, the whole thing wouldn't be worth while, except to the promoters. When Mr. SCHWAB took hold of the Bethlehem Steel Corporation he fought like a Trojan to have the preferred stock made non-cumulative as to dividends. He won his point after a hard struggle—and his foresight saved

him. It took long and weary years to develop the company.

Then, although the elimination of competition does away with a great measure of overhead expenses, as the speaker said, it permits low standards of material to be established. There is a nation-wide demand for better steel, better cement better materials for specific purposes. How could the One Great Company meet this demand with its ideals set on tonnage? The chance for improvement would be unfavorable. The One Great Company could do it—but would it? We think not.

We have no illusions of the blessings of competition. It has as many bad effects as it has good ones. But we believe it is the moderate-sized manufacturing concerns, that must strive for quality or quit, which have contributed most to improvements in the merchandise produced. As often as not it is their better quality of product which makes them grow great. Standard products are excellent in their way, but when we want something better we need to be able to get it.

No very big corporation can be administered without system and order. The bigger it is the more system must be established. But system is like competition: it has its merits and also its faults. Among the latter is its potency to destroy initiative Under too much of it a great deal of the best talent withers and ceases to function. We get standard qualities and such betterments as are planned for, but all the illumination that would have come from the minds that wither as soon as they must proceed in goose-step is lost.

We hope the One Big Company may never be established

In What Direction Goes Your Research?

SPEAKING in his own characteristic way, our good friend Dr. WHITAKER recently said: "At the end of 1918 we were like many other research organizations going strong, but not in the right direction." He was referring, of course, to the disinclination for peace-time pursuits that had resulted from the craze for war production. It occurs to us, however, that quite often our research is inclined in the wrong direction. Permit us to give an example or two that may serve to make our meaning clearer.

The other day a friend, for whose technical ability we have the greatest respect, came to us and in one of his happy moments confided news of his recent successful research. Without divulging his secret, we can, for our present purposes, assume that he has discovered a new substitute for honey. His product looks like honey and tastes like it Unfortunately it has no nutritive value, but it is harmless and, most important of all, not a single one of the usual chemical tests can distinguish it from honey. Furthermore, the product is cheap; it is made from corncobs. With it every apiculturist can turn out ten or a hundred jars of honey where only one, or maybe none, came before. Our friend's fortune is made, his invention is a success, but after all, what has he accomplished? He has merely invested his scientific talents in the forbidden field of adulteration; he has contributed nothing to the lasting good of his fellow men.

For our second example we must be permitted to draw a slightly different shade of meaning between the terms adulteration and sophistication. Research of rather questionable merit has carried us far in the latter direction. Not unnaturally many of our manufacturers have wanted to please the every whim and fancy of a whimsical public and to do this they have called for the help of the chemist. The soap maker, for example, wants to produce a white laundry soap because the housewife insists on such a product. In order to get it for her at a price she is willing to pay, the chemist is forced to add chalk or talc or some other inert filler in no small quantity. The addition of these materials helps to make a nice white product, but certainly it does not enhance the detergent properties of the soap. During the war some of us learned for the first time that large amounts of sugar were being used in making cheap transparent toilet soap, which has no advantage other than its appearance. However, the whim or fad of the customer is satisfied and that means business.

But it is not alone in the soap industry that the chemist is guilty of such connivance. The motorist, for example, demands a fuel that is without a disagreeable odor, that is bright and sparkling and will stay that way. Thanks to the chemist's wits such a product is available, but only after a refining process that adds to its cost and in some cases doubtless sacrifices its quality. Much the same condition exists in the field of lubrication.

Other examples might be adduced from practically all of our great industries, but these, we believe, are sufficient to point out a deplorable trend in some of our industrial research. The chemist himself may not be able immediately to correct this situation, but at the same time he should not lose sight of the fact that the greatest reward will come, not to the imitator or the mimic, but to the originator who leaves the beaten path and dares to search in new and untrodden fields.

Better Not Fool Ourselves

ABOUT a dozen years ago there was published a book called "All the Children of All the People," by WILLIAM H. SMITH, who was superintendent of schools in a Middle Western city. It is still in print, and well worth reading. Mr. SMITH's contention is that we make a mistake in trying to mold all young people into one form by means of standardized curricula. As to that we have nothing to say in these columns, but his illustrations are very illuminating to those of us who have to administer affairs, or who aspire to do so.

Every one of us, claims Mr. SMITH, is short in some respects and long in others. We are born short and born long; both. There was an Irish-American hired man, brought up near the old Five Points in New York City, who could make any plant grow; but he couldn't learn to read or write. A boy, one of the author's pupils, could not learn the multiplication table and remember it. He grew to manhood, become an inventor and large manufacturer, achieved remarkable affluence —but never knew the multiplication table. In telling this to a leader of the New York Bar lately he remarked, "That's my trouble. I know some of the items, but not all; then I have to add or subtract to get my figures." The writer's brother, a man of rare intelligence and sound judgment, never could learn the sequence of the alphabet. He could rattle it off up to l, m—but there he always became confused. A very able teacher could not tell the time by the clock, and neither could an eminent judge. He carried a watch, but only for show. Another man who wrote and pub-

lished excellent verse that is recorded in the anthologies, and was an able United States Consul in a leading European city, could not do long division. An idiot girl, inmate of an asylum, who could not read nor even count, could make any kind of lace with a crochet needle, if she only saw the pattern. The list could be continued indefinitely. The point is that we are born both long and short and often remain so. If we are born short, we may master the subject well enough to pass, to get along; but we are bound to make a poor showing in competition if we specialize on our short suits.

Many of us are short in administration; born short and remain short. Indeed the vast majority of us suffer from this very lack. We see it proved in the many failures that occur as a direct result of faulty administration. And yet only a very few of us seem to know this. Administrative posts are well paid, and of course we want the pay. But we are so short in administrative intelligence that we are blind to our own defects; and we court failure and distress that we should gladly avoid—if we only knew enough.

It is not distinguished or agreeable or even honorable to boss a job unless one can do it well. Otherwise it causes misery all around and brings the onus of failure upon the man who undertakes it. It is not even profitable except for the little while it takes to prove the man to be no good. Surely it's better to do a thing well than to command others to do it. Why this false ambition to command? It is far better to look inward, to discover our real talents, and then to develop them and to rejoice in doing well that which we can do well. If we try seriously and try hard we can find out better than all the psychologists and mental testers together. But we shouldn't fool ourselves. We must be honest about it.

Indefinite Repetition Would Be Intolerable

THREE statements in the preliminary report of the Coal Commission express the essence of the public's interest in the industry:

"With resources of coal in the ground adequate for the needs of perhaps a hundred generations of Americans, the nation's coal bin is too often depleted and too often the prices paid for coal are much higher than seem warranted by the wealth of coal available."

"These experiences of unsatisfied demand and unsatisfactory prices have created in the popular mind a conviction that the natural benefits to be expected from a condition of plenty have been denied through artificial interference."

"The widespread public dissatisfaction with the service rendered by the coal industry is not confined to matters of shortage and price, for a train of unfortunate consequences has followed those recurring periods of scarcity: deterioration in the quality of fuel delivered; congestion of railway traffic, necessitating the neglect of other freight to give preference to coal, to the serious harm of other business; and breakdown of mutual confidence of producers and consumers of coal as expressed in the customary contractual relations."

And well does the commission add, "Every industry and every citizen throughout the country is directly or indirectly dependent upon coal." Of the dependence of the chemical and metallurgical industries there can be no question, for over a third of the entire bituminous coal consumption is by industries involving technical processes or chemical control. The commission then continues:

"It is clear that an indefinite repetition of these crises in the production and distribution of coal would be intolerable." This is a statement in which every branch of industry and every clear-thinking individual will concur.

It is not strange that the commission in less than three months has not been able to reach formal conclusions on the important problems presented to it. But it has made definite progress in establishing satisfactory fundamentals that require thorough investigation and some decision as to national policy. The main points of the preliminary report are very illuminating.

One of the causes of high prices of coal in some instances has been profiteering; the instability of the industry has been largely due to labor troubles; and car shortage at times of coal scarcity and high price is undoubtedly an important transportation deficiency. The commission discusses these three factors briefly, but passes on to the problem of over-development as apparently of equal or greater importance; and whether one considers that this over-development is itself a cause of the other troubles or a result of them is immaterial.

The effect of over-development is clearly shown by the commission to be an added cost to coal consumers for the maintenance of 200,000 miners and their families above the needs of the country for miners and the burden of capital charges on something like a billion dollars. It is high time that the national policy with respect to such matters as these be determined.

Very few will disagree with the query in the final paragraph of the report. All will simply hope that the right answer may be reached at an early date:

"The commission believes that the public interest in coal raises fundamental questions of the relation of this industry to the nation and of the degree to which private right must yield to public welfare. It may be that both private property in an exhaustible resource and labor in a public service industry must submit to certain modifications of their private rights, receiving in return certain guarantees and privileges not accorded to purely private business or persons in private employ."

Co-operation in Statistical Work

THE government is issuing at this time many requests to industries for a statistical report on their operations in 1922, looking forward to the annual reports on these industries. In some cases these questionnaires become so numerous and are so lengthy that one is tempted to throw them all in the waste basket in disgust. But in the long run that is poor policy.

The government through its careful, regular study of industrial operations of all sorts furnishes impartial, reliable statistics of great value. There is no industry which would not profit by knowing more of itself. The next time these questionnaires come, it will be well to stop and remember that it is the industry which is served, not any bureaucratic office or academic official.

Prompt, accurate and complete returns on the part of every operator will speed up the results greatly; and in work such as this, promptness in issuance of the data will add greatly to their value. It will be well to co-operate in work of this sort so that there need be no break in the continuity or question as to the reliability of the figures that are prepared.

Readers' Views and Comments

Why Not Get Away From Traditions?

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Dec. 27 issue of *Chem. & Met.* Mr. Nasmith takes the phrase "Why not get away from traditions?" literally. The expression (not mine, by the way) did not suggest getting away from *all* tradition, but only from that which has a hampering influence.

It is evident that Mr. Nasmith is experienced in the baking art but in his defense of tradition overlooked an opportunity to explain why oven walls are built as thick as 25 in. He believes in the importance of "solid heat" and "flash heat," yet does not offer a definition of the terms. It is probably true that many points of disagreement would be cleared up or eliminated if disputants should at the outset agree upon definitions of terms.

In the case under discussion "flash heat" probably means the subjection of the goods to the action of the comparatively high temperature of radiant heat while passing over the fuel bed; this to get the "rise." "Solid heat" is probably what is termed in other industries "soaking heat," and is furnished by the hot gases; this is the baking heat.

An oven wall of 25 in. thickness is probably one extreme. The oven described as made of a steel shell covered with insulation is the other. Somewhere between these extremes is the correct design. As the brick walls exert a regulating or "flywheel" effect on temperature, only such mass of brickwork should be used as is consistent with this regulation and with the structural requirements. A wall thickness of 21 in. and 25 in. is, I think, quite as ridiculous as a steel shell insulated on the outside. The former has the advantage, however, in that the fault is one involving economics of construction and will not manifest itself to the operator.

A consideration of the specific heats, or heat capacities, of brickwork and the insulated-steel oven should suggest a brick lining in the latter of about two courses, or 9 in. More than this would be superfluous because of the low temperature involved (less than 600 deg. F.), and because the brickwork is heated on one side only and consequently cannot exert a maximum "regenerative" effect. One can be assured that the temperature found a few inches from the heated surface of oven brickwork can have no useful effect on baking; and even if the temperature were high enough the time required to make this heat available would be too great to assist in reducing rapid fluctuations of temperature within the oven.

The experience of the proprietor of the bakery who was forced to replace a new and efficient type of oven by an older and less efficient one, simply because the operators could not or would not operate it efficiently, illustrates a point raised in my first letter—that is, mental inertia. Some operators are of a bovine mentality and any departure from old practice is frequently resented. Often the resentment is followed by deliberate, but secret, efforts to "queer" the new apparatus. If this condition is to be met by surrender as in the case quoted, then progress may as well take off its hat and sit down.

I can appreciate the feelings of the operating staff of the chemical plant that was left with a monstrosity on the departure of the designing engineer. What seems curious is how he managed to do it. Where was the staff during construction? Was it the vogue to turn the design over to inexperienced men, and then fail to keep informed on what was being done? This looks more like clever salesmanship than honest-to-goodness engineering.

Because "the one in the arts who really knows cannot and does not express himself in writing," it does not follow that "the one who writes seldom does so from experience." Mr. Nasmith knows better than that.

Kansas City, Mo C. O. SANDSTROM.

Galvanic Corrosion on Yacht Sea Call

To the Editor of Chemical & Metallurgical Engineering

SIR:—It may interest your correspondents A. Hough, Robert J. McKay and Henry Howard and your readers generally that a very similar case to that of the Sea Call occurred in Ceylon about 16 years ago. A passenger steamer was built by a well-known Colombo engineering firm to the order of a native shipping company, in conformity with specifications of the latter, which provided for a sheathing of sheet copper outside a steel hull, with the object of insuring a clean bottom in tropical waters. The vessel had been in commission for only a very short time when, on a voyage off the coast of Ceylon, the captain, noting her weird behavior, wisely decided to beach her. He barely succeeded in running her ashore when the corroded steel hull fell apart at the water line. An interesting lawsuit ensued between the shipping company as plaintiff and the contracting shipbuilder. The Supreme Court of Ceylon upheld the latter as not responsible for a defect arising from the customer's own specifications and not specifically provided against in the contract.

The trouble arose through the specifier ignoring the fact that electrochemical action ensues between two dissimilar metals in close proximity when, both touching, they are immersed in an electrolyte such as sea water. The already known protective action of copper plating was harmlessly effective in keeping wooden hulls clear of marine vegetation and barnacles, and no electrolytic action took place so long as only one metal was involved which was passive to sea water. In the case of an iron or steel vessel, however, copper is strictly inapplicable, because of the difference of electrical potential which sea water establishes between the copper and the steel, in virtue of which the steel assumes an electropositive condition and becomes eaten away in consequence, while acting as a generator of electricity which flows to the copper. The copper itself, being electronegative, is not acted on, and naturally suffers no corrosion.

In the case of the Sea Call the Monel metal would behave somewhat similarly to copper in relation to steel, and therefore, while corrosion of the latter would be

bound to take place, the homogeneous Monel metal would remain unaffected.

All such similar arrangements may be considered as the analogue of a simple galvanic cell, in which a zinc and a copper element are immersed in an acid solution or electrolyte. As is well known, the zinc is consumed in the action of such a cell, and so with iron, steel or any other electropositive element, but the copper or electronegative metal suffers no loss.

If any of your correspondents or other readers are interested further in the Ceylon case, I will gladly furnish them with more details.

PATRICK T. MACNAMARA.
Late Superintendent of Ceylon Telegraphs
Brooklyn, N. Y.

Dirt in Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial on "Dirt in Steel" in your issue for Jan. 10 stirred one of my friends to the point where he asked me to step into his chamber of horrors. What I saw would have caused a Ku Klux from Morehouse to bolt over the line into Arkansas. But as he (this friend, not the Ku Klux) is one of those retiring fellows who never break into print, he would not accept my suggestion that he write you himself. So when I left, I took some of his exhibits with me, concealed in my greatcoat.

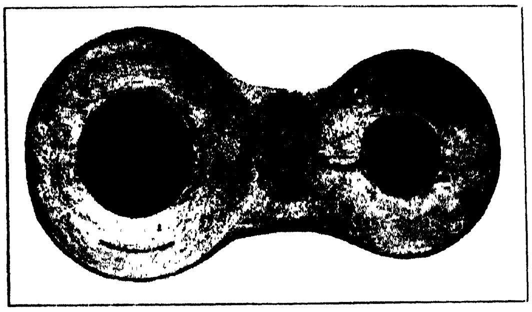

FIG. 1—SPRING SHACKLE, PICKLED SOMEWHAT REDUCED

It appears that some spring shackles were giving a great deal of trouble—wearing out too soon or something like that. When they were sectioned and pickled as in Fig. 1, it showed that what steel there was, was segregated, but there was little steel—it was mostly slag. Note the slag in Fig. 2. No, Mr. Editor, this was not a casting.

I believe that in the Hartford region the first thing they do with troublesome steel is to pickle it 30 minutes in 1:1 HCl, and see the pock marks.

At another place my friend found that the shop had made some keys from a supposedly high-grade tool steel, yet they gave a great amount of trouble, cracking and shearing off. Fig. 3 shows the high-grade tool steel. No, Mr. Editor, it is not raisin bread or "spotted dog" of pleasant memory.

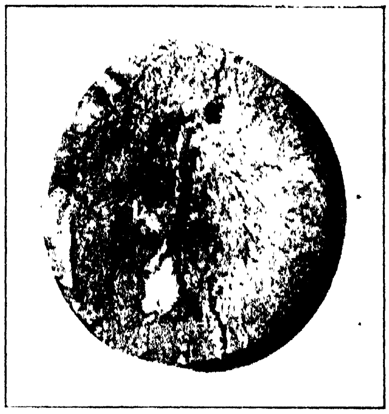

FIG. 4—FRACTURE OF ALLOY SHAFT

One of the most puzzling things was an alloy steel shaft. It was returned from the erecting shop, undoubtedly broken and of most extraordinary cross-section, looking like Fig. 4. Its analysis was O.K., and under the miscroscope it looked all right, too—properly sorbitic and all that. But when someone had a happy thought and repolished the section and looked at the steel again, he saw what is shown in Fig. 5. No, Mr. Editor, it is not an airplane view of the Allied trenches at Mons.

There was much more to the same effect, but this was all I could readily abstract without detection. It will suffice to give an idea of the tons of evidence you could find to support your main contention that many troubles with steel are not due so much to the metal as to the dirt.

MARTIN SEYT.

Manufacture of Spark Plug Porcelain

Porcelain Bodies Developed by Careful Scientific Research Are Formed Into Spark Plug Cores With the Aid of Specially Designed Semi-Automatic Machinery

BY ALAN G. WIKOFF

As USED in the spark plugs of automobile engines, porcelain is required to withstand sudden changes in temperature without cracking or chipping and also to remain a good insulator even at increased temperatures. In airplane engines, the service requirements are even more severe, since the motor is operated continuously with the throttle wide open. The amount of scientific research which is required in the development of porcelains having the necessary properties for successful application in plugs is perhaps not fully realized until attention is called to the fact that one of the companies in this field maintains one of the largest research organizations in the entire ceramic industry. As the company is also a very large producer, a discussion of its methods will give an idea of the high degree of development which has been reached in the spark plug industry.

The Champion Porcelain Co.,* formerly the Jeffery Dewitt Co., was organized in Newark, N. J., in 1908 to manufacture complete spark plugs. In 1910 it moved to Detroit and as the demand for the spark plug porcelains grew it began to devote its entire efforts to the manufacture of porcelain, discontinuing the assembling of the complete plugs.

The Champion Spark Plug Co., of Toledo, became one of the largest users of these porcelains and finally, about 1917, its demand required the entire output of the Jeffery Dewitt Co.

In 1920 there was an amalgation of the two companies, the Champion Porcelain Co. now being a subsidiary of the Champion Spark Plug Co.

Ball clay, china clay, kaolin, flint and feldspar from a variety of sources form the raw materials for the porcelain body. An essential requirement is that each should be extremely low in iron. The first step in the manufacturing process is to combine the raw materials in such proportions that the resultant body will have as low a thermal expansion and will be as good an insulator at high temperatures as is possible with present knowledge. The batch composition necessary to give these properties has been determined only after thousands of experiments. In accordance with recent developments, the finished porcelain has a composition approaching that of sillimanite.

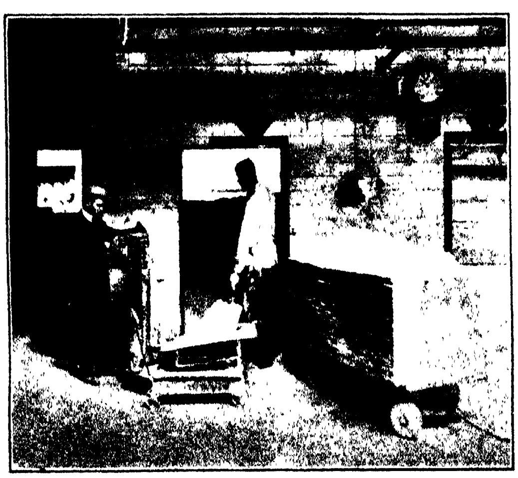

FIG. 1—WEIGHING BATCHES

Batches are weighed out as shown in Fig. 1 in amounts sufficient to form charges for the ball mills. A measured amount of water is added to each charge and the mill is operated for a definite period which is determined by the number of revolutions rather than by the time. In this way uniform grinding results are obtained. There are five 6-ft. Abbé pebble mills driven by individual motors through Link-Belt silent chain (Fig. 2). Porcelain mill-lining blocks and balls made in the plant are being used with excellent results.

The ground batch is dumped into agitators, where a uniform suspension is produced which is filtered through

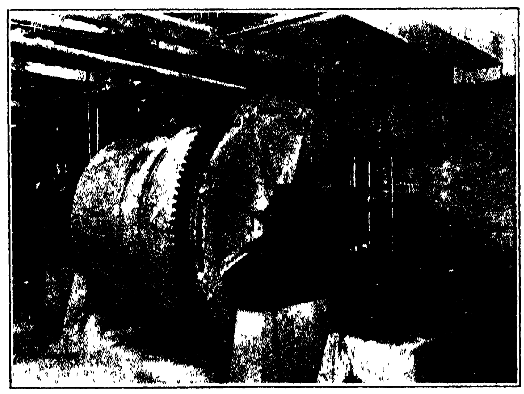

FIG. 2—PEBBLE MILL FOR GRINDING BATCHES

120-mesh lawn and then fed to the four Crossley filter presses, Fig. 3. The press cakes are piled on a skid and transferred by a lift truck to the horizontal pug mill shown in Fig. 4, in which any tendency toward segregation of particles in the press is overcome, the clay being discharged as a cylinder quite homogeneous in character.

Further improvement in the quality of the body is obtained by the process of aging. The clay is worked in piles, Fig. 5, by pounding with wooden mallets, Fig. 6. After the proper time has elapsed it is taken out on skids and pugged once more, this time in vertical American or Crossley machines, Fig. 7.

It is interesting to note that the only manner in which material can enter or leave the production department is by way of an elevator equipped with a Toledo platform scale so that a check can be kept without difficulty.

From the thoroughly pugged clay, cylindrical blanks about 1 in. in diameter with a ¼-in. hole through the center are formed on Crossley vertical pug mills which have been rebuilt specially for this purpose. From these blanks the spark plug cores are made. Many difficult problems were encountered in attempting to redesign these machines so as to overcome segregation, lamination, uneven distribution of air and other defects which would interfere with the high degree of uniformity required.

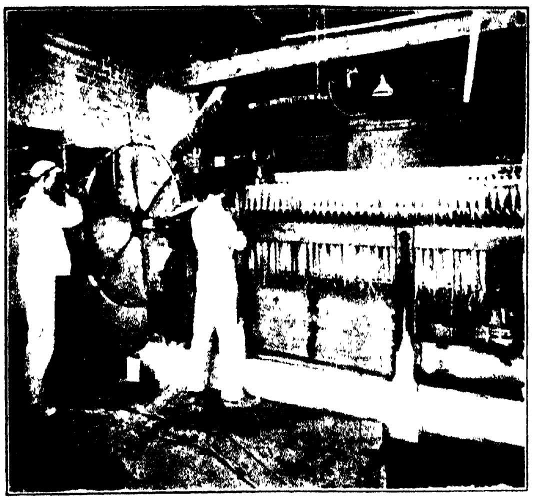

FIG. 3 FILTER PRESSES

As the perforated cylinder comes from the pug pieces of the required length are cut off by means of wires. Each of the twelve machines has a capacity of about 27,000 blanks per day. The blanks are placed on trays holding about 170 and allowed to air-dry for 24 hours in racks accommodating forty trays, before passing to the steam-heated tunnel drier. These operations are illustrated in Fig. 8. The racks are brought to the drier on a monorail hoist and rest on platform cars while passing through, Fig. 9. Temperature and time factors are adjusted so that all drying shrinkage or air shrinkage is removed. Control is maintained through a Tycos wet and dry bulb recording thermometer at the cold end, steam pressure recorder at the coils and a temperature recorder at the hot end of the drier.

Thorough drying brings the blanks to a condition which renders comparatively simple the operation of shaping. Specially designed grinding machines, Fig. 10, are used for this purpose. The blanks are placed on the spindles or on the centers depending upon the exact nature of the piece being made and rotated against a rapidly revolving silicon carbide wheel, the face of which is dressed to such a contour as to impart the required shape to the blank.

After receiving their external form the turned pieces are transferred to another position on the same machine and the petticoat is formed by counterboring with a formed tool which rotates at high speed. During this operation air is blown continuously through the bore in order to remove all dust. Both the turning and counterboring operations, however, are performed simultaneously.

The completed forms are placed on trays provided with suitable supports so that the forms are separated to prevent abrasion and chipping. Trays of dry blanks are sold to the girl operators and bought back on the basis of the number of perfect forms. One form in each tray is stamped with the batch number and the end is dipped in cobalt sulphate solution. On firing the form will develop a blue color, and as the capacity of a tray is the same as that of a sagger, each sagger will contain an easily distinguishable marker bearing the batch number.

Although the grinding operation is complete in considerably less than a minute, the blank has been reduced to about one-third of its original weight. Consequently, it has been necessary to provide for the removal of an amount of dust equal to approximately twice the output of finished product. This is handled by a twelve-unit

FIG. 5 AGING THE CLAY

dust recovery installation. The bulk of the dust accumulates in troughs under each row of machines, from which it is removed by means of a screw conveyor. The remainder collects in bags which are rapped automatically at intervals to remove the deposits.

When the amount of dust produced is considered, the almost complete absence of dust in the atmosphere of the grinding room is remarkable.

Owing to their special nature, it has been necessary

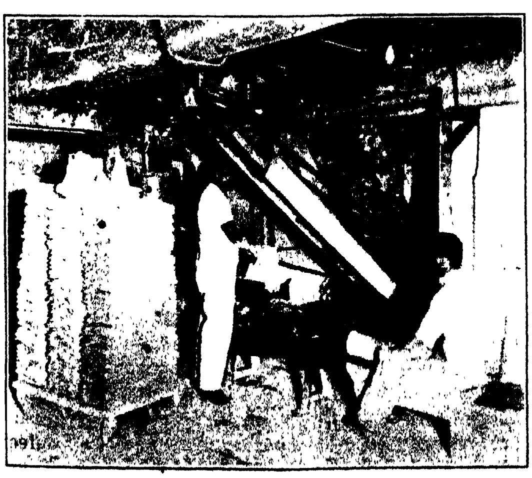

FIG. 4—PUGGING PRESS CAKES.

FIG. 6—WORKING CLAY DURING AGING

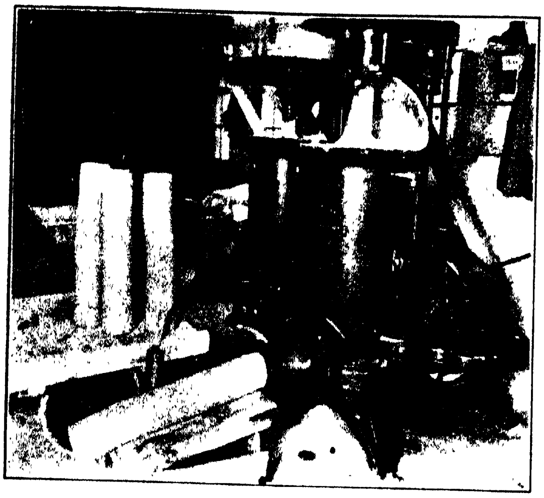

FIG. 7—PUGGING THE AGED CLAY

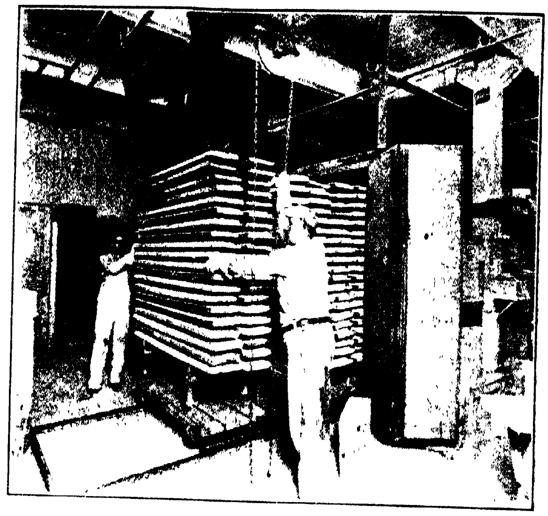

FIG. 9—TUNNEL DRIER

to develop and make the grinding machines within the establishment. An interesting variation is the machine used to make the balls for the mills. A small shop is devoted to the preparation of the grinding wheels, the surface being cut out on a lathe with a diamond-tipped tool guided by hand. Here also the worn wheels are redressed.

Application of a carefully selected glaze completes the operations prior to burning. The raw materials—clay, flint, feldspar, whiting—are ground very fine in porcelain-lined mills and distributed to the spraying machines in the form of a slip, the viscosity of which must be very closely controlled in order to obtain optimum results. The composition is such that the glaze will have as high a hot dielectric capacity as possible. Composition ranges for glazes maturing between cones 17 and 20, as set forth by Robert Twells, Jr.,[1] will give some idea of the formulas used for high-fire glazes.

Recently a method for selecting glazes within a field where all of the glazes appear equally suitable has been described by F. H. Riddle and J. S. Laird.[2] It was found that glazes which fit the body increased the tensile strength over that obtained for the unglazed body, while glazes which craze weaken the specimens very markedly. Appearance of the glaze alone is likely to be very misleading.

[1]J. Am. Ceramic Soc., vol. 5, p. 430, July, 1922.
[2]J. Am. Ceramic Soc., vol. 5, p. 500, August, 1922.

Spraying takes place on the ingenious machines shown in Fig. 11. Mounted on rapidly revolving spindles, the forms are carried past sprays of glaze slip so arranged that all parts receive an even coating with the exception of the shoulders, which would stick together in the saggers if glazed.

The glazed ware is set directly into a sagger—a round refractory container—as shown at the left, Fig. 11. A special composition applied to the inside bottom of the sagger provides a sticky surface which holds the forms upright and separated during the handling which precedes burning. In the kiln, the paste of course burns out, but the ware remains in place unless violently disturbed.

So severe are the burning conditions that the life of an ordinary fireclay sagger averages about one heat. Silicon carbide saggers have sufficiently greater life to more than offset the difference in first cost and are giving excellent service at the present time.

Periodic round downdraft kilns were formerly used exclusively for burning the spark plug porcelain. During 1919 a Dressler tunnel kiln was installed so that the periodic kilns are now in service only occasionally. However, it may be of interest to consider both types briefly in order to contrast the methods of burning.

Each of the six periodic kilns is equipped with eleven thermocouples (ten base metal and one noble element) connected with a Brown electric pyrometer. City gas is

FIG. 8—BLANK-FORMING DEPARTMENT

FIG. 10—CORE-GRINDING DEPARTMENT

used as fuel, the pressure being kept constant to within $\frac{1}{16}$ in. by means of gas boosters and regulators. Heating conditions are watched through twenty-one peep-holes, firing being continued to cone 17 down (1,470 deg. C.; 2,678 deg. F.).

Saggers are stacked in the kiln with a clay wad or seal between the rim of each sagger and the bottom of the one above it in order to exclude the products of combustion and also to enable the placing of each sagger in a level position so that the ware will not stick together. Setting and drawing are laborious operations, as the heavy saggers have to be handled on ladders in the upper parts of the kilns. Fig. 12 gives an idea of the drawing process.

For the Dressler tunnel kiln, which is of the muffle type, the saggers are set on cars as indicated in Fig. 13. The lower part of the cars consists of a cast-iron frame with roller-bearing trucks. Above this is a superstructure of refractory blocks which serve to protect the iron from excessive heat. The saggers are not placed directly on the car floor, but are supported on brick piers so as to permit free circulation, which is essential in this kiln.

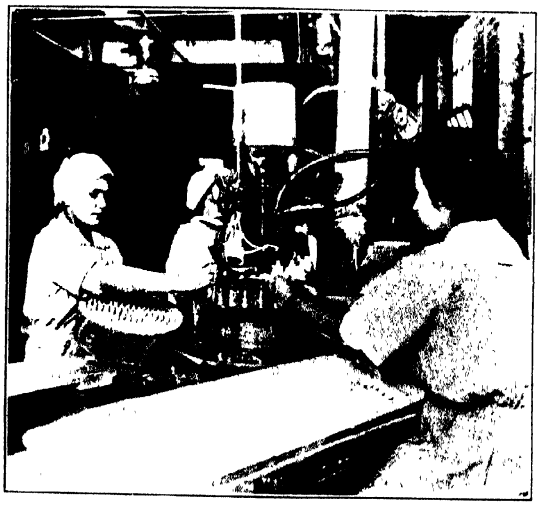

FIG. 11—SPRAYING ON THE GLAZE

The cars shown are at the loading and unloading station on the track which runs parallel to the kiln for its entire length. Before entering the kiln, the loaded cars must pass through the heavy guard at the right, Fig. 14, in order to make certain that there are no projections which might cause trouble within the kiln A transfer truck moves the car in line with the kiln track.

As the kiln is always filled with cars—forty-eight in this case—the introduction of a car of green ware means the simultaneous removal of a finished car at the other end. Pushing mechanism powerful enough to move the train of forty-nine cars is provided in the form of a mechanical pusher. There are automatic control buttons which stop the cars should the pusher fail to stop when the proper point has been reached, thus preventing a car being pushed through the wall at the exit end. It is also impossible to push out a car until the transfer truck is in its proper position.

Operation is ordinarily on a 1-hour basis, that is, one car is entered and one withdrawn every hour, making the time of travel through the kiln 48 hours. A 1½-hour schedule has also been used.

The kiln itself is 305 ft. long with an arched roof or crown and platforms or bench walls on each side of the track corresponding in height with car floors. All arrangements for heating and cooling are supported on these platforms. The heating zone, Fig. 15, which extends from the mouth of the kiln to a point a little beyond the center, has horizontal combustion chambers on either side. For a distance of about 30 ft. in the zone of maximum temperature these chambers are built up of double-walled carborundum blocks assembled in a special trapezoidal form, Fig. 16. As the temperature diminishes toward the mouth of the kiln, the chambers are continued first with fireclay construction and then with iron pipes in the section nearest the entrance.

FIG. 12—DRAWING PERIODIC KILN

Combustion takes place near the center of the kiln and the products of combustion are drawn through the internal chamber toward the mouth of the kiln by an exhaust fan. Heat transfer takes place by conduction through the inner walls with radiation from the outer walls in the high-heat zone and also by convection currents set up in the channels between the double walls. As the combustion gases are not permitted to escape into the kiln, the character of the kiln atmosphere may be controlled as desired.

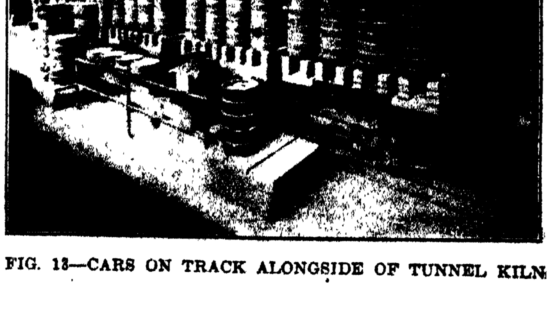

FIG. 13—CARS ON TRACK ALONGSIDE OF TUNNEL KILN

FIG. 14—LOADED CAR ENTERING TUNNEL KILN

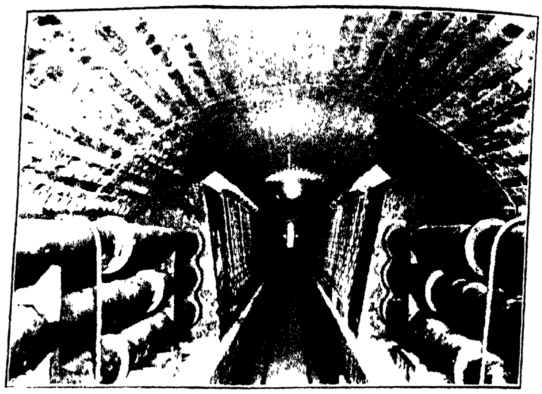

FIG. 15—HEATING END OF KILN

City gas is used as in the case of the periodic kilns. It is interesting to note that, so far as is known, this is the only kiln which is operating at from cones 18 to 20 down (2,714 to 2,786 deg. F.; 1,490 to 1,530 deg. C.) Being the first to operate at such high temperatures, this kiln has been experimental so far as the refractory lining of the high-heat zone is concerned. For the muffles, carborundum seems to be the only refractory which will give satisfaction. The kiln arch throughout the furnace zone is built of silica brick. The top and sides of the kiln are covered with insulating material. Further protection for the iron work on the cars is afforded by a series of water-cooling pipes extending along each side of the tracks through the furnace zone, a distance of about 75 ft. A sand seal is not necessary in this type of kiln.

During their progress through the heating zone, the cars of ware are brought gradually to the required temperature. Heat exchange between combustion flues and cars is such that on a 1½-hour schedule the combustion gases leave the kiln at 480 to 550 deg. F. This is lowered somewhat on a 1-hour schedule.

Leaving the high-heat region, the cars enter the cooling zone, Fig. 17, which constitutes the remainder of the kiln. From the discharge end of the kiln, cool air passes through pipes along the sides, absorbing heat from the convection currents, which are guided by the curtain wall shown at the right, Fig. 17. When this photograph was taken the left-hand curtain wall had not been completed, so that the cooling pipes are visible. Preheated air for the burners is obtained in this way, but there is also a considerable surplus which may be used for drying.

Since the cars move on a fixed schedule and it is thus impossible to give them individual attention as regards time of heating or soaking, uniform control of kiln conditions within rather narrow limits is essential for successful operation. Accordingly, a very complete set of indicating and recording pyrometers, draft gages, combustion meters, etc., has been provided. The operating installation is housed near the kiln, while another set for check and permanent record is located in one of the laboratories.

Because of the fact that temperature conditions in each part of the kiln remain constant, the ware receives more uniform treatment than is possible in a periodic kiln, and the yield of No. 1 ware is increased. Labor requirements are cut practically in half and the more efficient utilization of heat reduces the fuel consumption by about 70 per cent. Working conditions are also improved, since loading and unloading are done in the open on the track along the side of the kiln. With the periodic kiln the men inside must often work at uncomfortably high temperature, while the man in the doorway (Fig. 12) is in a strong draft.

Rigid inspection for dimensions and the possible existence of defects follows burning.

When thoroughly satisfied as to the quality of the product, it receives the familiar trademark. Formerly decalcomania—transfer paper bearing the design in the form of an inorganic pigment mixed with a suitable binder—was used, the design being fixed by firing to cone 015 (1,472 deg. F.; 800 deg. C.) in regular decorating kilns.

Now the design is applied by a rotating rubber stamp to the work, which is carried to it by a turntable carrying twenty spindles on which the work is placed by the operator. Each decorating unit, Fig. 18, consists of one of these printing machines and a tube furnace containing twenty electrically heated tubes through which the cores move much after the manner of cars in a tunnel kiln. As each piece is decorated it is placed in a slot in front of the tube. As each revolution of the turntable is completed a cross-head carrying twenty plungers advances and forces the entire row of plugs into the tubes, causing the ware within the furnace to advance a corresponding amount, thus discharging a row of finished plugs at the lower end. During the

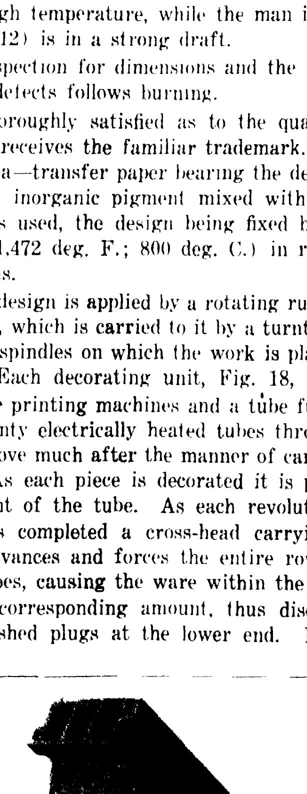

FIG. 16—CONSTRUCTION OF ELEMENTS FORMING COMBUSTION CHAMBER

peration the plugs are heated to about 800 deg. C. and ooled down in a comparatively short time, so that this aethod constitutes an excellent heat test in addition to liminating the handling required in connection with he decorating kilns. Five of these electrical units turn ut the entire production, which is then shipped to the Champion Spark Plug Co., at Toledo, where the metallic parts are assembled with the porcelain to form the finished spark plug.

B. A. Jeffery, vice-president and active head of the production and service departments, is responsible for a great many of the special mechanical features which make the processes different from those used in the average plant and which have done much toward increasing the efficiencies of the various processes.

RESEARCH DEPARTMENTS

Without complete knowledge and intelligent application of fundamental scientific data, the production of modern high-grade ignition and high-tension porcelain would be impossible. No other organization in this field has shown greater appreciation of this fact, for Dr. Jeffery, president of the company, has built up a research staff of six highly trained technical men with nine assistants and has provided them with every facility for conducting precise investigations. The research department, which is under the direction of Frank H. Riddle, is made up of five laboratories—control, chemical, raw material, electrical and process. Ceramic research is also conducted here for the Jeffery-Dewitt Insulator Co., Kenova, W. Va., so that the latter company receives the benefits of this highly-developed organization.

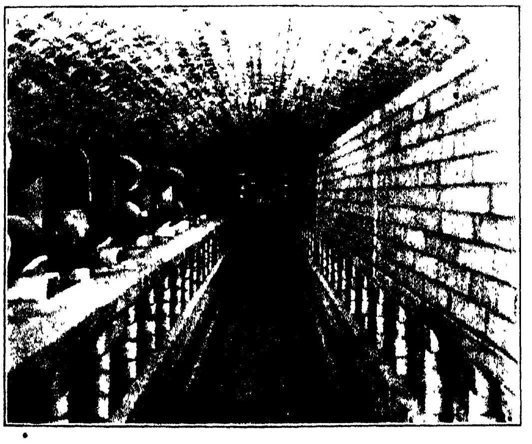

FIG 17 COOLING END OF KILN

In the control laboratory, Fig. 19, the blue markers from each sagger are subjected to test before the rest of the plugs are released for shipment. Here also experimental bodies are tested before the batches go into production.

For the continuous-heat test, the plugs are mounted on the rim of a horizontal disk which in rotating passes them through a stream of cold air and then through the flame of a Meker burner. This apparatus will be seen on the table beside the bookcase at the left. Heating the plugs for 1 minute over a Meker burner and rapping them sharply while hot constitutes the 60-second test.

Against the wall in the background is the equipment for the hot dielectric test. A constant voltage is passed through the plug while it is being heated in an electric muffle furnace and the temperature at which the porcelain ceases to be an insulator is recorded. Leakage is shown on an indicating wattmeter. The present product cuts out quite regularly at 1,700 deg. F. Maintenance of a constant voltage presented a problem which was finally solved by converting alternating current to direct current and back to alternating current again with regulators on each step.

FIG 18 DECORATING UNITS

Impact tests are made by placing the plug in a holder so that one end protrudes and subjecting the exposed part to blows from a steel hammer which slides on a vertical graduated rod, seen on the corner of the table at the extreme right. The weight is dropped from a noted height and if breaking does not result, the operation is repeated from the next higher graduation and so on until the specimen breaks.

On the table in the center of the picture is a 2,000-lb. Olsen cement-testing machine provided with special grips for determining the tensile strength of porcelain.[1] The test specimens have either conical or dumb-bell shoulders, and the central portion of minimum cross-section is left free from glaze to avoid the effect of the glaze in increasing or decreasing the strength of the specimen. The recording instrument room for the Dressler tunnel kiln is also part of this laboratory. Structure of the finished product is studied by means of an excellent petrographic microscope.

[1]See "The Tensile Strength of Porcelain," by F. H. Riddle and J. S. Laird. *J. Am. Ceramic Soc.*, vol. 5, p. 385, July, 1922.

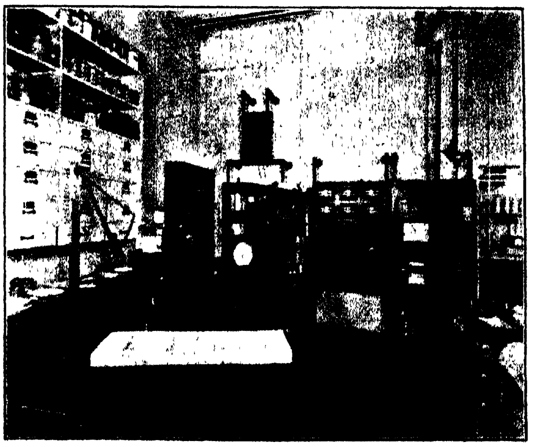

FIG. 19—CONTROL LABORATORY

FIG. 20 RAW MATERIAL LABORATORY

Equipment for complete silicate analysis is provided in the chemical laboratory, which also has a comparometer and a Joly balance for specific gravity determinations.

In what may be called the raw material and production batch following laboratory, screen analyses up to 300 mesh are made on each mill charge, shrinkage is determined on each press cake and a record of firing on raw materials is filed. Fig. 20 shows part of this laboratory, with the mercury volumeter for determining shrinkage, fired clay disks, feldspar cones, and viscosimeter at the right. The firing tests on raw materials are filed in the cabinet at the left.

A continuous production record is kept, in which progress of the batches through the various manufacturing processes is indicated by colored lines, a different color being used for each batch.

One of the primary functions of the electrical laboratory is to make and calibrate thermocouples. The calibration outfit is of the Bureau of Standards potentiometer type. There is also a very sensitive device for determining the thermal expansion of porcelain heated in a Crisco bath. An electrically heated apparatus now in process of development will enable this determination to be made at 1,000 deg. C. Measurements of electrical conductivity and dielectric properties can also be made.

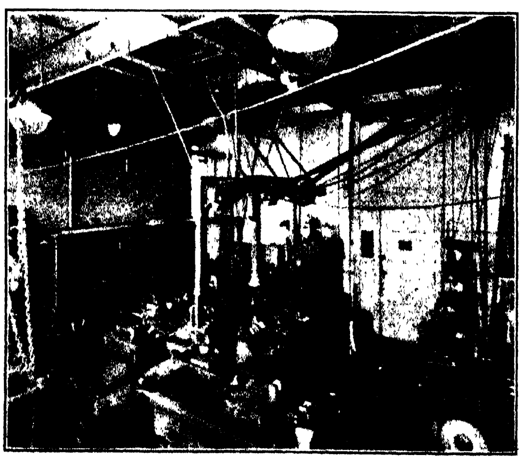

FIG. 21—PART OF MECHANICAL AND ELECTRICAL LABORATORY

Since much of the special apparatus is best made within the department, a small but well-equipped machine shop has been included. This is shown in Fig. 21, with some of the electrical equipment at the left.

As far as possible, the process laboratory (Figs. 22 and 23) contains one unit of each type of machine in the plant so that development work can be carried right through to large-scale units without interfering in any way with the production departments. It is thus possible to know beforehand exactly how a new body will behave when placed in production.

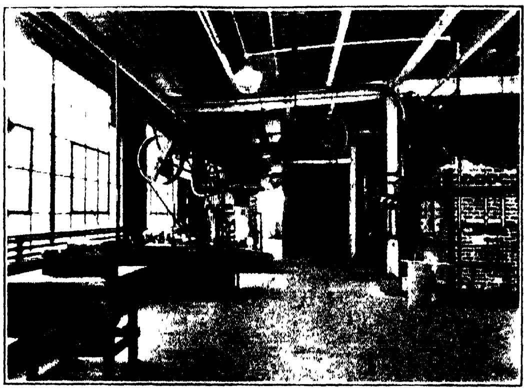

FIG. 22 FURNACE END OF PROCESS LABORATORY

The inclusion of a full-sized pebble mill would be out of the question, of course, but a number of small ball mills have been calibrated accurately in terms of larger plant units.

Along the window side of the laboratory (left, Fig. 22; right, Fig. 23) there is the following equipment: A full-size pug, a half-size pug, a glaze sprayer and a grinding unit of five machines. In the background at the left of Fig. 23 is a drier with complete temperature and humidity control, while the surface combustion furnace which duplicates kiln conditions as nearly as possible is shown at the right, Fig. 22. There is also a small surface combustion furnace with alundum crucible on which it is possible to reach cone 36 (3,362 deg. F.; 1,850 deg. C.).

FIG. 23—GENERAL VIEW OF PROCESS LABORATORY

For determining porosity, the fuchsine penetration test is used. Fuchsine dissolved in methanol (because

this solvent will absorb many times its own volume of air) is forced into the porcelain under high pressure. Upon breaking the specimen, the penetration, if any, is easily observable.

Preliminary lots of blanks where the quantity is too small for the pug are thrown by hand on a wheel.

All pyrometer protection tubes used in the plant are made in this department, a tube press, casting racks and molds being provided for this purpose. The results have been so satisfactory that experiments are being conducted toward the commercial production of these tubes.

It would be difficult to find a plant in which co-operation between research and production departments is more complete, and the results which have been obtained speak for themselves regarding the value of such co-operation.

Data and illustrations for this article were made available through the courtesy and assistance of Dr. J. A. Jeffery, president, B. A. Jeffery, vice-president, and Frank H. Riddle, director of research.

Theoretical Derivation of the Vapor Pressure Curve of Xylol

Novel Method of Calculating the Curve by Studying the Vapor Pressure Curves of Its Homologs

BY DEXTER C. EDWARDS

A SEARCH of the literature of coal-tar products showed a large number of determinations of the vapor pressures of benzol, toluol and naphthalene at various temperatures, but no figures were available for the vapor pressure curve of xylol. Since it was desired to have a close approximation to this curve for some experimental work, an attempt was made to derive it theoretically.

The line of reasoning back of the scheme adopted was as follows: All substances have zero vapor pressure at the temperature of absolute zero. Likewise all substances have a vapor pressure of 760 mm. of mercury at their boiling point. The next step in the reasoning was that, though the relative paths followed between these two points varied, yet for any particular class of substance this path would be the same in its relative proportion.

Vapor pressure curves were then plotted for benzol, toluol and naphthalene from the data available for these substances in Landolt-Börnstein, Beilstein and other sources, all values given being used and the curves drawn through the average of these points. These curves were plotted between Centigrade degrees and millimeters of mercury. Separate large-scale curves were plotted for the lower range of temperatures in order to be able to read accurately the corresponding vapor pressures. From these curves, the vapor pressures for these three substances at definite temperatures were obtained. These data are given in Table I. Then the absolute temperature for each of these temperatures was placed in the adjacent column. The next column contains a row of figures obtained in each case by dividing the corresponding absolute temperature by the absolute temperature of the particular substance at its boiling point.

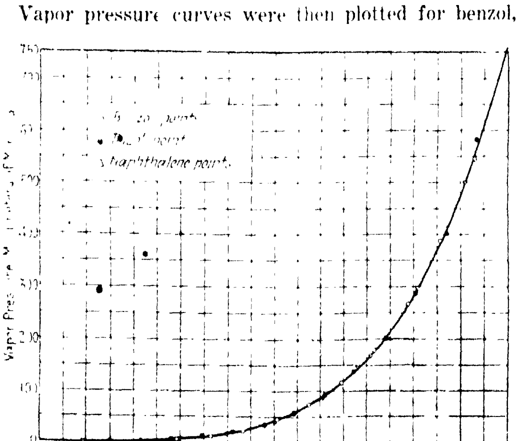

FIG. 1—CURVE FROM WHICH VAPOR PRESSURE OF XYLOL WAS CALCULATED

200	473	.964	500.0
218 B P	491	1.000	760.0

The derived value of the ratio of the absolute degrees Centigrade at any point, divided by the boiling point of that substance in absolute degrees Centigrade, as shown by column 3 in each table, is plotted against the corresponding vapor pressure, on the curves in Fig. 1. These points are seen to fall on the same curve, when drawn on this scale, so the variation in any case would not be very great.

Since this curve shows that these three substances have the same shape vapor pressure curve, then it is logical to assume that the vapor pressure curve of xylol should have this same shape. This being true, it is possible to work backward to the vapor curve of xylol. For this purpose it is necessary to assume a boiling point for xylol. The figure chosen is 140 deg. C., which

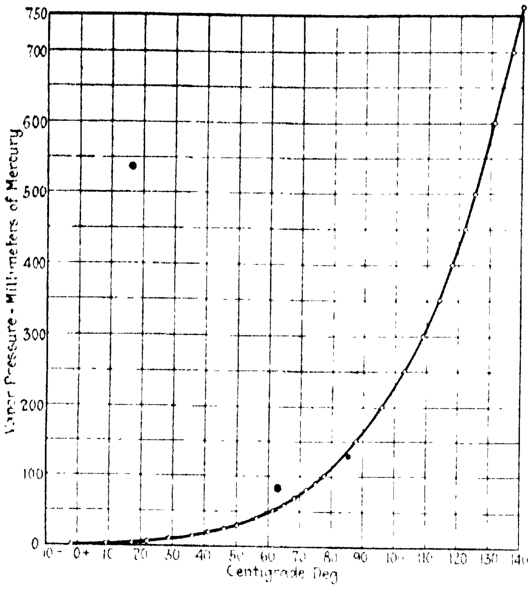

FIG. 2 CALCULATED VAPOR PRESSURE CURVE OF XYLOL.

is about the average of the three isomers, ortho, meta and para xylol. Next, a column of vapor pressures is set down as shown in column 1 in Table II. The values for the ratio corresponding to these vapor pressures are next obtained from the curve drawn from the data in Table I. These are placed in column 2. Each of these ratios is then multiplied by the absolute boiling point of xylol, 413 deg., thus producing the figures shown in column 3. These figures, less 273 deg., are the corresponding temperatures in Centigrade degrees, and are shown in column 4.

TABLE II VAPOR PRESSURES OF XYLOL

Xylol			
1 Vapor Mercury mm Mercury	2 Absolute Deg Absolute B P	Deg C Absolute	4 Deg C
1	657	271	2
3	683	282	9
5	702	290	17
7	715	295	22
10	731	302	29
15	749	309	36
20	762	314	41
25	773	319	46
30	782	323	50
40	797	329	56
50	808	334	61
60	817	338	65
70	827	341	68
80	836	345	72
90	843	348	75
100	849	351	78
150	875	361	88
200	894	369	96
250	911	376	103
300	924	382	109
350	936	387	114
400	946	391	118
450	955	395	122
500	963	398	125
600	979	404	131
700	992	410	137
760	1 000	413	140 B P

The values in columns 1 and 4 of Table II are then plotted and produce the vapor pressure curve for xylol, shown in Fig. 2.

The writer frankly admits that he knows of no law permitting the assumptions made above. But owing to the fact that the three coal-tar substances benzol, toluol and naphthalene followed the same relative curve as is shown, it was thought safe to assume that xylol would behave the same way. In any case, the resultant error should be quite small.

Methods of Controlling Electron Currents in High Vacuum*

Most of the applications of high-vacuum tubes have depended upon the control of electron currents, as for example by the grid in the three electrode tube. The action of the grid is due to the charge on the grid modifying the space charge effect. This is the action that is employed in practically all tubes used today for radio transmission and receiving. There are many other methods, however, of controlling electron currents. A very important method is that used in the magneton, where there are only two electrodes in the evacuated space and the control is obtained by means of a magnetic field generated by an external coil of wire. A still simpler form of magneton suitable particularly to very large power tubes consists of a very large filament in the axis of a cylindrical anode with very large straight filaments. The magnetic field produced by the current through the filament is enough to prevent electrons flowing between cathode and anode. By heating the filament with alternating current, the current periodically falls to low value and at these times current can flow to the anode. This gives a pulsating or oscillating current, which can be used for radio transmission. A 1,000-kw. tube of this kind is in process of development; preliminary tests have been in every way satisfactory.

Another form of tube by which electron currents can be controlled is the Dynatron. This depends upon subjecting one of the three electrodes in the tube to electron bombardment in such a way as to cause electrons to be splashed out of it, just as water can be splashed out of a cup by attempting to fill it too rapidly from a faucet. A tube of this kind acts like a real negative resistance, and can be used for producing electrical oscillations with considerable efficiency.

One of the most important applications of electron discharges from hot cathodes is in the Coolidge X-ray tube which is now almost universally used as a source of X-rays. These tubes were first made about 1913 and are gradually being improved in many respects. The latest type of tube, suitable for use by dentists, is a small tube weighing only a few ounces and only about 3 in. long. Because of the special features of this tube, the entire X-ray outfit, including the transformer, lead screen, regulating apparatus, etc., weighs only a few pounds and takes up a space of only a small fraction of a cubic foot. One very great advantage of this new form of tube, besides its convenience is its absolute safety, even in the hands of inexperienced operators, for there are no high voltages in any part of the apparatus which is accessible.

Canadian Mineral Production Higher in 1922

The Dominion Bureau of Statistics announces that its preliminary estimate of the mineral production of Canada during 1922 shows that the total value amounted to $180,622,000, an increase of practically $6,000,000 over the production of the previous year.

The value of the metals produced was $61,731,000, as compared with $49,343,232 in the preceding year; fuels and other non-metallics dropped $4,000,000 to a total of $83,891,000 and the production of structural materials and clay products has been estimated at the same valuation as last year—namely, $35,000,000.

In the metals the outstanding feature was the production of gold, which reached a total of 1,200,000 oz.

*Abstracted from a lecture by Dr. Irving Langmuir, Pittsburgh, Pa., Nov. 28, 1922.

Effect of Chemical Solutions On Various Woods Used in Tanks

By S. J. Hauser and Clarence Bahlman
The Hauser-Stander Tank Co., Cincinnati, Ohio

What Kind of Wood Can We Use With Such a Solution?—In What Way and How Extensively Do the More Common Chemicals Affect the Most Industrially Important Woods? — These Questions Are Comprehensively Studied in This Article

ALTHOUGH wooden tanks have been extensively employed for containing chemical solutions, little attention has been paid to the kind of wood best suited for any specific liquid. Very often a manufacturer hesitates to purchase wooden tank equipment because both he and the tank builder are uncertain as to the ability of the material to withstand the action of the solution in question. With this in mind, the writers undertook to determine, in a limited way, the effect of various chemical solutions, in varying concentrations and at different temperatures, upon the more important woods used in tank construction. It was not expected that these experiments would solve all of the problems, but it was believed that much valuable light might be thrown upon the subject.

Of course, the life of a wooden tank, or vat, in industrial use is governed not only by its resistance to the contained chemical but also by the skill and care used in its construction as well as the way it is used and the care given it by the plant operatives. Laboratory experiments alone may not definitely determine which wood is most suitable for a specific purpose, inasmuch as practical experience and the various physical properties and defects of the different woods have a great influence in the proper selection; still they are a wonderful help in making a decision. Very often laboratory results assist materially in explaining the failure of a wooden tank on the one hand and help to avoid future failures on the other.

We therefore feel justified in submitting our results, incomplete as they are in a somewhat condensed form, believing that they will furnish a clearer conception of just what might be expected of certain tank woods when exposed to chemical solutions.

The following six woods were used in these experiments: red gulf cypress, Douglas fir, long leaf yellow pine, California redwood, hard maple and white oak. Uniform test strips (4x1x½ in.) were prepared from thoroughly air-seasoned lumber and only such pieces as were free from knots and other defects were employed in the experiments.

Our experiments were confined to a study of the effect of various hot and cold solutions upon the different woods, determining the absorption of the liquid, expansion or contraction of the wood and other physical action such as softness, brittleness, warping, etc. Also, the relative amounts of color and taste imparted to water by the various woods were recorded. The strips were completely submerged and a separate container was used for each kind of wood.

The common acids, alkalis and salts, as well as linseed oil, turpentine and distilled cottonseed oil fatty acids were employed. For absorption and expansion or contraction the strips were weighed and calipered, then immersed in the cold solution for a week, when examinations were made again. After this they were returned to the solution for 3 weeks more and the physical examinations were made. Where hot solutions were used the strips were immersed for a week, and each day the solutions were brought up to boiling for 1 hour. Tests were also made on strips coated with asphalts, pitches and various so-called acidproof paints.

After the desired period of immersion, the strips were removed and dried on the outside with a rag, and then permitted to remain for 15 minutes exposed to the atmosphere before weighing or calipering. The increase in weight was expressed as grams absorbed per strip—i.e., per cubic inch—and also as percentage gain in

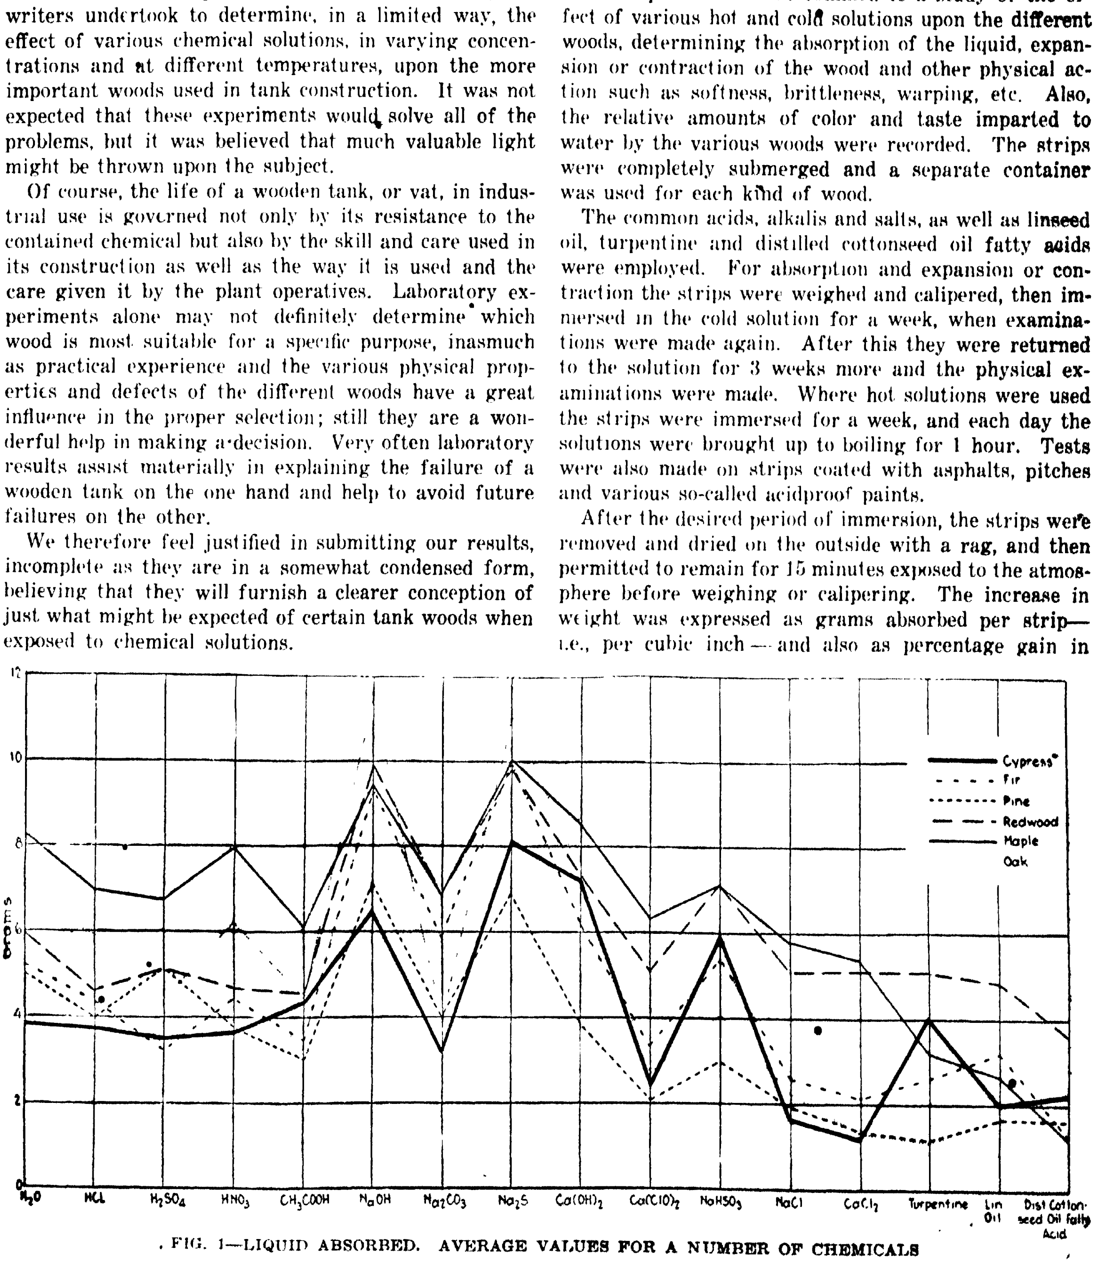

FIG. 1—LIQUID ABSORBED. AVERAGE VALUES FOR A NUMBER OF CHEMICALS

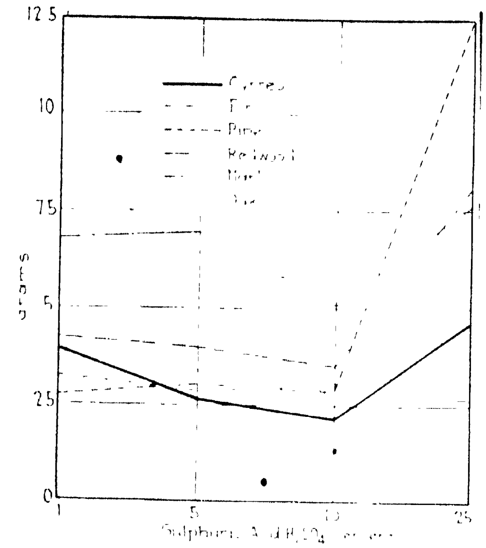

FIG. 2—LIQUID ABSORBED. H_2SO_4 AT VARYING CONCENTRATIONS

weight. The increase or decrease in dimensions at this point was designated as Temporary Expansion or Contraction. The strips were then permitted to dry under atmospheric conditions for one week, after which they were calipered again, and this result was expressed as Permanent Expansion or Contraction.

After these examinations were made, the strips were returned to their respective solutions and kept submerged for 3 weeks more, when they were removed and their physical condition noted. A record was also kept of the color imparted to the liquid. With the hot solutions, instead of waiting 15 minutes after removing the strips therefrom before weighing or calipering, they were weighed and measured shortly after removing the excess liquid and drying with a rag.

EXPERIMENTAL RESULTS

Effect of Wood Upon the Solutions—Obviously there are two effects for which we would be on the lookout in these experiments. One is the effect of the wood upon the solution, and the other is the effect of the solution upon the wood. So far as the former effect is concerned, the color and taste of the solution after having been in contact with the wood were observed. These coloring matters may be due, of course, either to matter extracted from the wood without pronounced chemical action, or to substances formed by the chemical action upon the wood, or perhaps to both. Pronounced colors, however, usually indicate destructive action.

Oak and redwood both yielded pronounced color to water within 24 hours. Maple imparted only a slight coloration after 48 hours, while cypress, fir and pine did not color the water in 2 weeks. Boiling tests were also applied to strips of wood, fresh water being used each day on 8 successive days. Color was imparted to the solution every day by oak and redwood, on 5 days only by fir and maple, although a slight coloration was observable on the succeeding 3 days. With cypress there was a strong color for 3 days, slight color the day following, and then no coloration whatever on the 4 succeeding days. Pine gave a strong coloration for 2 days only, and a slight coloration throughout the remaining six.

The water used in the foregoing tests was tasted in each case and it was found that boiling water intensified the taste but gave the same general resuts as follows: Pine gives a pronounced taste to the water throughout the test, whereas cypress gives none at all. It can be concluded from these tests that cypress, inasmuch as it imparts neither taste nor color to a solution, would be easily the best wood to use for making tanks for food products.

With acids and alkalis, the colors extracted from the woods vary somewhat with the strength of the chemical used, but in general gave the same order of receptivity, cypress giving the least color, the redwood and oak the most.

The Effect of the Solutions Upon Wood—It is, of course, nearly impossible to get any absolute standard of reactivity of a given solution upon a given wood. Therefore some rather empirical standards have been adopted. The first is the quantity of liquid absorbed by the wood, and the second is the expansion or contraction of the strip of wood during the action. In addition, of course, there are also the appearance and physical conditions of the strips themselves aside from any quantitative measures.

QUANTITY OF LIQUID ABSORBED

The results of the many tests have been condensed into charts and tables, and it is hoped that the type of results obtained may be interpreted from these charts. Fig. 1 shows the amount of liquid at room temperature absorbed in grams by the strips of wood. The results of the different concentrations have been averaged and the points represented on the chart are therefore average points. In general it will be noted that the curves seem to vary somewhat similarly. In other words, one solution is more readily absorbed by all the wood than another solution. In general too it will be noted that maple and redwood absorb more than cypress. A good many other interesting minor points can be observed by studying the chart, but it must be borne in mind that the tests are not absolute tests and the results are recorded in empirical units.

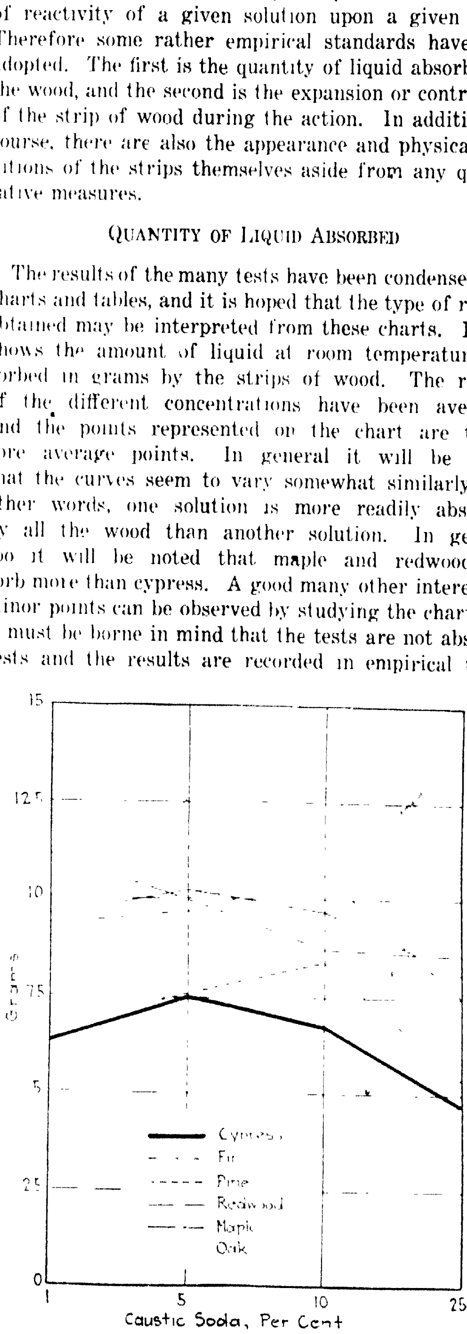

FIG. 3—LIQUID ABSORBED. NaOH AT VARYING CONCENTRATIONS

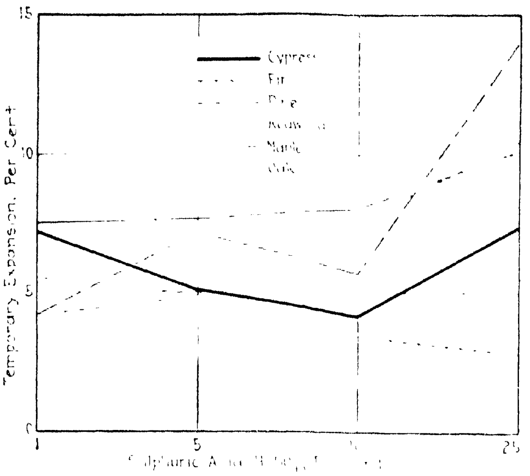

FIG. 4—EXPANSION IN H_2SO_4 AT DIFFERENT CONCENTRATIONS

However, it is certainly true that corrosion should vary somewhat directly as the amount of liquid or solution absorbed, and one would expect, therefore, to find more corrosion and disintegration of the wood which absorbs more of the solution. The results obtained with hot liquids are not given here, but were similar to those obtained with the cold liquids, as a rule greater absorption taking place with the hot liquids, although there were a few exceptions to this rule.

As was stated above, the values for any one wood in a given solution are average values, and it may be added here that as the concentration of the solution increased, the quantities absorbed varied irregularly. This was in some ways a surprise, for it was expected that the absorption would either increase or decrease as the strength of the solution varied. To bring this point out more definitely, Figs. 2 and 3 represent the effect of varying concentrations of sulphuric acid and caustic soda on the different woods used. It is perhaps significant to note that the general shape of the curve is in each case somewhat identical, but more quantitative conclusions are probably not warranted. Similar results were also obtained with hot solutions and with other chemicals not listed.

Expansion and Contraction

Variations in the contraction or expansion of the different woods used were also noted, and the irregularities for different strengths of the solution were apparently as vagrant as those noted under the amount of liquid absorbed. Figs. 4 and 5 show the expansion or contraction observed when the different woods were immersed in sulphuric acid and caustic soda of varying strengths. With cold solutions all the woods showed temporary expansion. The permanent expansions are not shown in the chart and are considerably more various than the results of the temporary expansion. In general there was less expansion and in some cases contraction. Hot liquids also showed a definite tendency to contract the woods. Still another measurement, that of shrinkage upon drying, was made roughly, and not unnaturally the shrinkage was rather great when the samples were dried after being removed from hot liquids. Cypress and pine were the only woods, upon drying, that did not show contraction in any of the cold solutions. The tendency of certain chemicals to cause swelling or shrinkage is probably best shown by using the figure obtained after the various woods had dried for a week following immersion in either hot or cold liquids. Fig. 6 indicates the effect of the various liquids at room temperature upon the different woods. The permanent expansion or contraction caused by certain hot liquids is shown in Fig. 7. In all cases, however, the various woods showed greater expansion or less contraction, as the case may be, before being dried than after drying.

Physical Condition of the Wood

Perhaps the most interesting set of data is that obtained by studying the physical condition of the strips of wood after removing them from the solution. In general, water solutions of salt, such as calcium chloride, sodium chloride, organic liquids, such as turpentine, linseed oil and the cottonseed oil fatty acids, produced no effect either in hot or cold solutions. Cold calcium hydroxide and cold solutions of sodium bisulphite had no effect. Sulphite of soda in the cold produced no noticeable effect except to soften redwood and had also a slight softening effect on the oak. Neither hot nor cold sodium carbonates had any noticeable action on any of the woods, except oak was somewhat shrunken after being removed from hot solutions. Considerable effect was noticed in the solutions of mineral acids and a table is herewith appended in which these effects have been summarized. Only four kinds of action are recorded in the table for simplicity's sake: Softening, warping or distortion, charring or shredding. A very great number, eighteen in all, were observed, all of them attempting to make some quantitative distinction in the effect noticed. In the table, however, any softening effect is

Note: A blank space represents no test

designated by a capital S. This softening effect may have been very slight or very severe, and it may have taken the direction of pliability, which is also included as a softening effect. There are many different kinds of action represented by the capital W, standing for warping. The strip may have been cracked lengthwise, warped in the usual sense of the word, badly distorted, noticeably shrunken or expanded, but these have all been included in the one term in the table. Charring and shredding are terms which need no further elaboration. In addition it should be noted that some of the woods are rendered distinctly brittle by the action of solutions. For example, hydrochloric acid, 5 per cent, renders redwood very brittle, and much stronger acid has the same effect on maple and oak, but no detrimental effect is noticed on cypress, fir or pine. Sulphuric acid also produces some brittleness in redwood, even at 1 per cent concentration, whereas 5 per cent acid has very little action on any of the other woods. Even 25 per cent sulphuric acid has very slight action on pine, and attacks cypress to only a small extent.

Perhaps we can summarize these qualitative conclusions by some definite statements as to the effect of the various solutions on wood.

Conclusions

Redwood and oak are objectionable from the standpoint of color.

Fir and pine produce pronounced tastes. Cypress imparts neither color or taste to any degree.

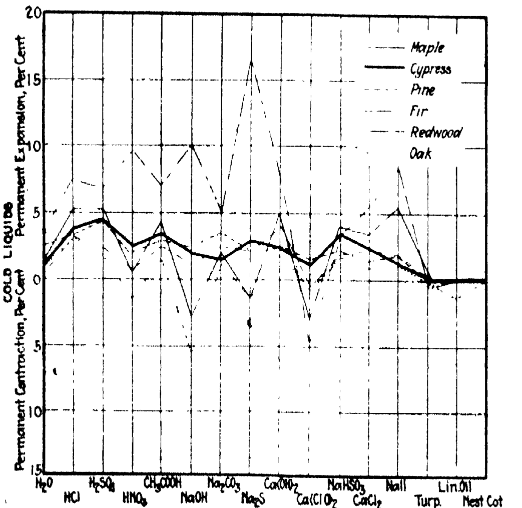

FIG. 6—EXPANSION OR CONTRACTION IN VARIOUS COLD SOLUTIONS

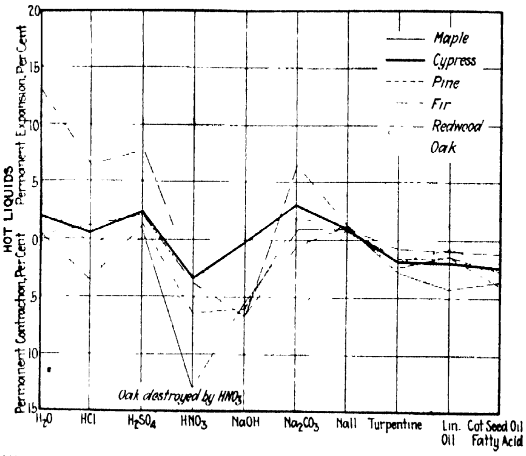

FIG. 7—EXPANSION OR CONTRACTION IN HOT SOLUTIONS

All of the woods absorb the various chemicals to a greater or lesser degree. Oak, maple and redwood have the greatest absorptive powers and fir, cypress and pine the least. Caustic soda and other alkaline solutions are absorbed to the greatest extent, followed by the acid solutions, then the salts and least of all the organic liquids.

Many of the liquids, particularly caustic soda, HCl, HNO_3, bleaching powder and the hot organic liquids, tend to cause shrinkage. This is most pronounced with oak and maple and the least pronounced with cypress and pine.

Nitric acid and caustic soda are the most corrosive of the various liquids tested, then H_2SO_4 followed by HCl and bleaching powder. Most of the other solutions had little or no corrosive action upon the woods.

There is always one wood (and often more) which is able to resist the action of the various chemicals at least in moderate concentrations.

Of the thirty-eight liquids used the number which noticeably affected the different woods at room temperatures (disregarding slight softness and roughening of grain) was as follows: Pine 4, cypress 7, fir 8, maple 13, oak 15 and redwood 22.

Protective Coatings

Waxes or gums, asphalts and coal-tar pitches are sometimes employed as a protective coating upon woods which are to be exposed to the action of corrosive liquids. These products may be either liquids or solids at normal temperatures. The liquids, usually called acidproof paints, are applied with a brush, whereas the solids are melted and then applied. In the latter case,

usually a prime coat of the same or similar material in liquid form is first applied to act as a binder. With those solids which have low melting points or no fixed melting point, as in the case of coal-tar pitch, some substance is frequently mixed with the protective material or else duck or burlap, properly secured to the tank and placed between coatings of the pitch, etc., is used to prevent the material from running down the vertical sides of the tank. Whether these preparations are successful in preventing the penetration of a liquid will depend upon the resistance of the coating to the action of the chemical and upon the completeness with which the pores of the wood are covered. Various coal-tar and asphaltic paints as well as solid materials were tested to determine their resistivity to the various chemical solutions. Melting point determinations were also made on the solid materials.

Most of the samples tested showed great resistivity to the various chemicals used but in the case of strips covered with liquid preparations, absorption took place, expansion or contraction occurred and the other physical manifestations were evident, although much retarded. It would seem that although the material itself was unacted upon, the chemical solution would get through the thin protective film and attack the wood. With the solid materials, especially when the wood was thoroughly and heavily coated, the penetration was very much reduced and thus very much better production was afforded.

From the tank builder's point of view it is desirable to receive information as to the purpose for which the tank is to be used, the chemical and strength of solution to be contained therein, the temperature of the solution and other conditions, as well as the dimensions. He will then be able to determine the proper wood to use, the thickness thereof, the correct metal for hoops or rods—i.e., whether iron, acid-resisting bronze, Monel metal, copper, brass, lead covered, etc.—the proper spacing and sizes of hoops or rods and their protection if necessary; the best method of construction bracing and supports, as well as whether or not linings or protective coatings should be employed.

Function of Magnesium in Fertilizer

Recent investigations by the Bureau of Plant Industry in co-operation with the North Carolina Department of Agriculture have shown that an important leaf disease of tobacco and other plants known to tobacco growers as "sand drown" is due to an insufficient supply of magnesium in the soil or fertilizer. In this disease the green and yellow pigments of the chlorophyll are affected and there is a blanching of the leaf tissues. This blanching invariably begins on the lower, older leaves of the plant and first symptoms usually appear at the tips and outer margins of the leaves.

Corn is affected in much the same way as is tobacco, the leaf blades presenting a striped effect. The disease occurs chiefly on light sandy soils and is more serious in wet seasons, hence the popular name "sand drown." It is an interesting fact that the disease is intensified by increase in the quantity of sulphates in the fertilizer. It has been found that this trouble is prevented by the application of comparatively small quantities of magnesium salts to the soil. The low-grade potash salts which contain magnesium, as well as dolmitic limestones, are effective preventives. Certain organic fertilizing materials such as cottonseed meal, tobacco stems and manure, which contain appreciable quantities of magnesium, tend to prevent the disease.

Coke Industry Recovered in 1922 Despite Difficulties

Byproduct Output Was 28,319,000 Tons—8,007,000 Tons of Beehive Produced—Ovens Consumed 53,311,000 Tons of Coal

BY R. S. MCBRIDE
Assistant Editor

THE year 1922 in the coke industry can well be characterized as one of recovery despite difficulties. The industry has continued to demonstrate that it is a splendid barometer of industrial conditions—perhaps even better than the iron and steel industry, which is commonly so highly regarded as an index of industrial development.

The estimated production of coke during 1922, based upon official returns of the U. S. Geological Survey for 11 months and estimates for December, is 37,326,000 tons, of which 28,319,000 tons was byproduct coke and 8,007,000 tons was from beehive ovens.

Byproduct coke has again outstripped beehive coke and more or less dominates the situation. One should not conclude from these data for the year as a whole, however, that the byproduct branch of the business is really more than three times as large under normal circumstances as the beehive branch, for during the middle of the year the beehive industry suffered more severely through strike conditions, especially in the Connellsville district. This fact is brought out quite clearly by the monthly production figures for the year, which are given in Table I.

BYPRODUCT OVENS END YEAR WELL

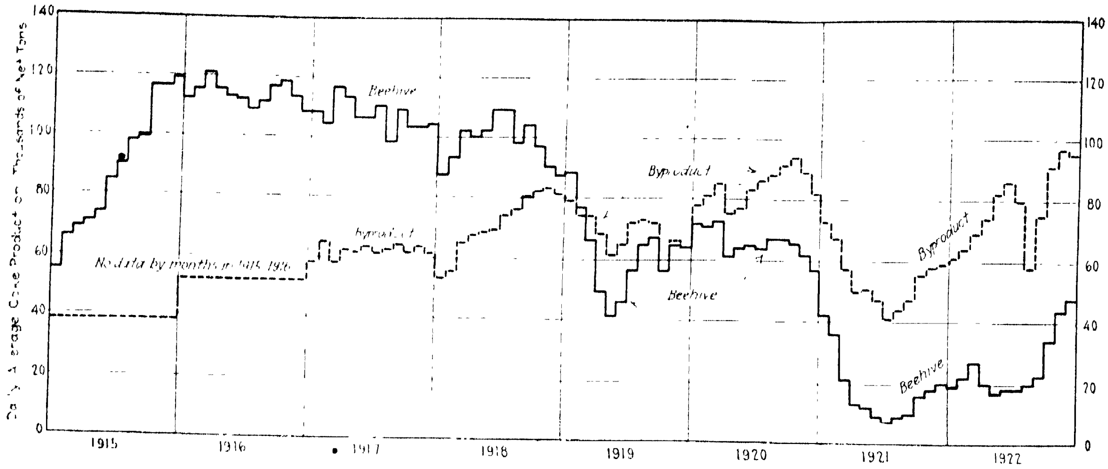
The byproduct coke ovens of the country were operating at approximately 50 per cent of capacity at the beginning of 1922. For the first 6 months of the year the activity of this branch of the business increased steadily, so that in June about 70 per cent activity was estimated by the U. S. Geological Survey. The coal shortage during July and August, however, cut down activities again, production during July being 68 per cent and during August only 49 per cent of the installed-oven capacity. With the resumption of adequate fuel supply in September a prompt renewal of activity ensued, and production during November and December was approximately 80 per cent of the entire installed-oven capacity of the country.

During the year there were regularly from ten to fifteen plants idle. Altogether sixteen plants were idle for a full month or more; but during no single month were more than fourteen of the total number, seventy-one plants, entirely shut down. Seven plants were idle the entire year. No new plants began operation during 1922, but a few ovens were added to some of those already in operation.

NEW OVENS CONSTRUCTED

At the beginning of 1922 three plants had new ovens under construction. These were the Woodward Iron Co., thirty ovens; Chicago Byproduct Coke Co., five ovens, and Milwaukee Coke & Gas Co., fifty ovens. All of these were completed during the year and some of them began operation.

The coke industry normally takes about 15 per cent of the bituminous coal produced in the United States. However, in July of 1922 there were used in the coke ovens then active approximately 28 per cent of the entire coal production that month. Of course with normal coal production, no such percentage of the coal would



PRODUCTION OF BEEHIVE AND BYPRODUCT COKE, BY MONTHS 1915-1922

In the earlier year the older type of ovens produced the more coke, but in 1919 the output of byproduct ovens passed the beehive and is now well in advance

TABLE I—COKE PRODUCTION IN 1922
(In Net Tons)

	Byproduct Coke		Beehive Coke		
	Production	Daily Average	Production	Daily Average	Totals
January	1,879,000	61,000	496,000	19,000	2,375,000
February	1,795,000	64,000	549,000	22,000	2,344,000

June	2,580,000	86,000	458,000	18,000	3,038,000
July	2,486,000	80,000	450,000	18,000	2,936,000
August	1,794,000	58,000	539,000	20,000	2,333,000
September	2,244,000	75,000	606,000	23,000	2,850,000
October	2,806,000	91,000	878,000	34,000	3,684,000
November	2,908,000	97,000	1,139,000	44,000	4,047,000
December (est.)	2,945,000	95,000	1,200,000	48,000	4,145,000
Totals	28,319,000	78,000	8,007,000	26,000	36,326,000

TABLE II—COAL CONSUMED IN COKE PRODUCTION, 1922 (In Net Tons)

	Byproduct Ovens	Beehive Ovens	Total
January	2,699,000	782,000	3,481,000
February	2,579,000	866,000	3,445,000
March	3,071,000	1,155,000	4,226,000
April	3,172,000	833,000	4,005,000
May	3,645,000	681,000	4,326,000
June	3,707,000	772,000	4,429,000
July	3,571,000	710,000	4,281,000
August	2,577,000	850,000	3,427,000
September	3,223,000	956,000	4,179,000
October	4,032,000	1,384,000	5,416,000
November	4,179,000	1,797,000	5,916,000
December (est.)	4,230,000	1,890,000	6,120,000
Total	40,685,000	12,626,000	53,311,000

ever go into coke ovens, but the quantity so used will undoubtedly be large at all times.

In Table II are given figures for the coal consumption in both byproduct and beehive ovens and the total of the two, by months. These figures are those estimated by the U. S. Geological Survey on the assumed basis of 69.6 per cent yield of byproduct coke from coal and 63.4 per cent yield of beehive coke and coal, the average yields for the industry during the preceding calendar year. The December figures are estimates.

At the beginning of 1922 there were in stock at many of the byproduct coke plants several hundred thousand tons of coke for which no market was available. Certainly at no previous time in the history of the industry was there ever on hand anything like this quantity of coke. However, as it became evident during the summer that anthracite would not be available in anything like the usual quantities, purchasers became increasingly interested in the use of coke as a substitute for anthracite. During midsummer the movement of this coke for gas making and for other industrial operations became active and with the early autumn it was an exception to find any unsold coke in stock.

The use of coke as a domestic fuel in place of anthracite has developed more slowly, but inability to get anthracite has compelled attention to this fuel and it is believed that thousands of households are served by coke which have never before used this fuel. This wide market, of course, promises to offer a balance-wheel for the industry which it has never before had. The exact tonnages so employed this year are not known, but it is certain that several times as much coke has been employed for domestic fuel as ever before.

New Constituent Found in High-Speed Steels

Recent work at the Bureau of Standards has discovered an unidentified constituent of relatively great hardness in two samples of high-speed steels. It had previously been found that electrolytic etching with weak solutions of ammonia and with sodium hydroxide has a very similar effect upon the various constituents found so far in alloy steels—namely, both solutions darken chromium carbide and tungsten carbide, while iron carbide and iron tungstide remain unaffected even after etching for several minutes.

The new constituent did not respond to the test for iron carbide and iron tungstide and did not assume any shape usually met with in the case of tungsten carbide. It did respond, however, to the test for chromium carbide—that is, it was darkened by either sodium hydroxide or ammonia. It appeared to be similar in behavior on etching to the very minute particles noted in the matrix of high-speed steel in the condition as received from the mill which were brought out by either ammonia or sodium hydroxide.

Since it would appear from the results of previous investigators that a large part of the chromium present in the high-speed steel is dissolved in the matrix (this would depend on the heat-treatment received), while a large part of the vanadium is present in the free state as carbide, it seemed possible that the constituent referred to above might be a carbide of vanadium. To test this an iron-carbon-vanadium alloy is now being prepared for study wherein it is hoped to have the vanadium and carbon present entirely as vanadium carbide.

Thermal Properties of Aluminum-Silicon Alloys

BY JUNIUS D. EDWARDS
Assistant Director of Research, Aluminum Co. of America

Accurate Determination of Densities of Aluminum Alloys Containing Variable Amounts of Silicon—Data at Various Temperatures Up to 1,000 Deg. C.—Data on Crystallization Shrinkage, Total Solid Shrinkage and the Tendency to Form Pipe

A RECRUDESCENCE of interest in the aluminum-silicon alloys has recently been effected by the discovery of methods of preparing them, and particularly of producing what may be called the modified alloys. The history and general properties of these alloys have been described by Jeffries;[1] reference should be made to this article for photomicrographs and descriptions of the structure of the alloys. Suffice it to say that the normal silicon alloys made by melting together silicon and aluminum in the proper proportions, and casting in green sand, exhibit relatively large plates and needles of eutectic silicon. The modified alloys show a very fine dispersion of the silicon and if there is excess aluminum above the eutectic ratio (which ratio varies somewhat with the degree of modification), it may appear as relatively large dendrites. The modified alloy may be produced electrolytically, and by treatment with compounds of the alkali metals with fluorine, as, for example, the method of Pacz.[2]

Another method[3] of producing modified alloys is by the addition of small amounts of metallic sodium or potassium, or both, to the molten alloy before casting. A description of this method by the present writer has already been published in this journal.[4] Modified alloys by this latter method are included in the series of density measurements here reported.

The thermal volume changes of the alloys of aluminum and silicon are believed to be unique among aluminum alloys. The character and magnitude of these changes have been investigated in a series of measurements of the densities of the alloys of aluminum with minor amounts of silicon at temperatures up to about 1,000 deg. C. These measurements have revealed many interesting facts and led to a clearer understanding of the mechanism of solidification of such alloys. Furthermore, they have provided fundamental data necessary for the most intelligent application and manipulation of the aluminum-silicon alloys.

EXPERIMENTAL METHODS

Methods developed in a previous investigation of the density of aluminum have been utilized and further developed in the present investigation. These methods have been described in *Chemical & Metallurgical Engineering*.[5, 6, 7] Density at room temperatures was measured by weighing in water and in air. The values for density are expressed as the mass of the metal in grams per milliliter and of course are comparable with weights *in vacuo*. Weighings made in air with brass weights on an equal arm balance will be about 0.03 per cent less.

Density of the solid alloys was measured at higher temperatures, by weighing in oil (Crisco) at temperatures up to about 250 deg. C. for the lower range and in a mixture of fused salts at the temperatures around 560 deg. C.

Density of the liquid alloy was measured in the densimeter, consisting of a graphite crucible of known volume, centered in a larger container. The whole apparatus is turned from a cylinder of graphite, so that there is an annular space surrounding the inner crucible which may be filled with a suitable molten metal to aid in producing a uniform temperature in the inner crucible which it surrounds. The crucible of known volume is completely filled with the molten metal at a temperature lower than that at which its density is to be measured. The cover is then screwed on tightly and the crucible raised to the desired temperature, by increasing the temperature of the electric furnace in which the apparatus is placed. The temperature is ascertained by means of a thermocouple placed in the metal bath in the annular ring. As the alloy within the crucible is heated, it expands and fills the known volume exactly; the excess metal runs out through two very small channels formed by the cover and two small grooves in the top face of the inner crucible.

When the desired temperature has been reached and maintained for a sufficient period to insure uniformity, any beads of metal extruded from the inner crucible are detached, the bath metal poured out, and the metal in the inner crucible allowed to solidify. When solid it can be removed and weighed. The volume of the crucible is determined at room temperature by filling with mercury and weighing the mercury. Its volume at the temperature of measurement is calculated from the known expansivity of graphite. From the weight and volume, the density of the alloy is readily calculated.

DENSITY OF AL-SI ALLOYS AT 20 DEG. C.

In Fig. 1 are plotted the results of density measurements on silicon alloys, normal and modified, containing from 0.5 to 18 per cent silicon, and cast in graphite and in sand. There is also included one sample of hard rolled sheet. Table I contains a selection of the numerical results, giving the chemical composition. The samples cast in graphite were cylindrical, and 1 in. in diameter.

The measurements were made at the prevailing room temperatures and all measurements have been corrected to the density at a uniform temperature at 20 deg. C. This correction was always less than 0.1 per cent of the density, so that it was sufficiently accurate to use an average expansion coefficient of 0.000022 per degree C. in calculating this correction.

The samples which were modified by the addition of alkali metal, were treated with approximately 0.05 per cent metallic sodium plus 0.05 per cent metallic potassium just prior to casting. The structure of typical normal and modified alloys is illustrated in references 1 and 4.

In alloy systems where there are no compounds formed, it is usually found that the specific volumes (the reciprocals of the densities) of the alloys will be very nearly a linear function of their composition.

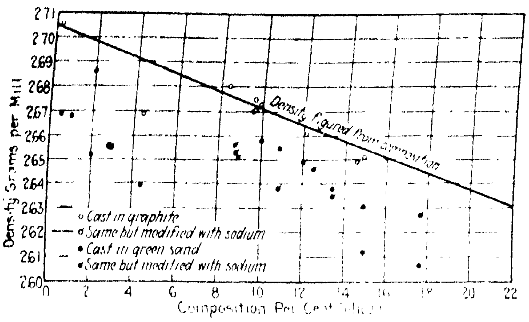

FIG. 1—DENSITY OF ALUMINUM-SILICON ALLOYS AT 20 DEG. C.

According to Richards,[7] the density of silicon at 20 deg. C. is 2.42. The density of aluminum of the purity used in making these alloys is about 2.705

The density curve of the alloys, calculated on the basis of such a linear relation between the specific volumes, is represented by the solid line in Fig. 1. The specimens cast in graphite, and having presumably the lowest porosity, are closely grouped along this graph. The densities of the sand-cast specimens containing approximately 2 and 4 per cent silicon were very much lower than this curve, and even after remelting and casting in graphite were still below the curve. The question arises as to whether the large variations in density observed with alloys of practically the same composition are caused by structural changes or are merely the result of variations in porosity. The density of the samples modified by the addition of a very small amount of alkali metal is slightly lowered. However, the lowest densities are not characteristic of the greatest grain refinement. The lowest densities are observed in the sand-cast specimens, whereas the greatest grain refinement is secured in the modified alloys chill cast. This would seem to indicate large variations in "porosity" of some kind. However, practical experience has demonstrated that aluminum-silicon alloys are unusual in their lack of permeability to liquids so that pore spaces if present must be isolated and small.

Frilley[8] has recorded a series of measurements on the density of the aluminum-silicon alloys. His data on the 10 and 20 per cent silicon alloys are about 5 per cent lower than the values given in the present paper. The reasons for these low results are not apparent.

DENSITY OF SOLID ALUMINUM-SILICON ALLOYS AT HIGHER TEMPERATURES

In order to complete the density curves up to the melting point, the densities of two representative normal alloys were determined at temperatures of 200 deg. C. and 563 deg. C. These determinations also permitted an approximate calculation of the expansivity. Density at the lower temperature was determined by weighing

the sample in air and when immersed in Crisco at a temperature of 200 deg. C. The density of the Crisco was determined at the same time as the weighing of the alloy by means of a platinum cylinder whose volume was accurately known.

A slow change in composition of the Crisco at this temperature made it difficult to secure an accuracy greater than 0.2 per cent. A new sample of Crisco was used for each series of measurements, and its density was checked by repeated weighings of the platinum cylinder.

Weighings at 563 deg. C. were made in a fused mixture of lithium and potassium sulphates. According to Nacken, quoted in Landolt Bornstein Tabellen, there is a eutectic mixture of these two salts which freezes at 535 deg. C. and contains 20 mol per cent of potassium sulphate. I used a mixture containing about 25 weight per cent of potassium sulphate, and found it quite satisfactory, although the freezing point of the salt (about 540 deg. C.) and the melting point of the aluminum-silicon eutectic (577 deg. C.) gave only a very small temperature range to work in, and made the measurements tedious and difficult

DENSITY OF LIQUID ALUMINUM-SILICON ALLOYS

The graphite densimeter was used for determining the density of the liquid alloys. The density of relatively pure aluminum is known from the previous measurements referred to, and the effect of the addition of 8 and 12 per cent silicon was observed in the present series. Results are given in Table III.

These alloys were all normal alloys. The modified alloys, strictly speaking, exist only in the solid state, because the modification is a structural change taking place during the crystallization of the liquid. A liquid alloy with alkali metal added has only the potential property of becoming a modified alloy.

TABLE III—DENSITY OF LIQUID ALUMINUM-SILICON ALLOYS

Composition					
Si Per Cent	Fe Per Cent	Cu Per Cent	Al Per Cent	Temperature Deg. C	Density g. ml
7.81	0.39	0.12	91.68	663	2.413
7.81	0.39	0.12	91.68	802	2.375
7.81	0.39	0.12	91.68	904	2.345
11.63	0.45	0.11	87.81	643	2.441
11.63	0.45	0.11	87.81	801	2.392
11.63	0.45	0.11	87.81	904	2.356

A graph of these results indicates the expansion of the liquid alloy to be practically linear from the melting point to at least 1,000 deg. C., and the greatest deviation from a straight line fitted to the data is less than 0.1 per cent. In Table IV are given convenient values for these alloys as taken from the plotted graphs. Fig. 2 shows the freezing points of the aluminum-silicon

alloys containing from 0 to 15 per cent silicon, and Fig. 3 a series of isotherms giving the densities of these alloys at 700, 800, 900 and 1,000 deg. C.

The normal eutectic composition is usually given as about 10 per cent silicon. Fraenkel[10] reported 10 per cent and a eutectic temperature of about 576 deg. C. Roberts[11] reported 10 per cent and 578 deg. C.

Observations made in the course of the present work indicated a normal eutectic temperature of approximately 577 deg. C. and a eutectic composition between 11 and 12 per cent, or more exactly, 11.6 per cent of

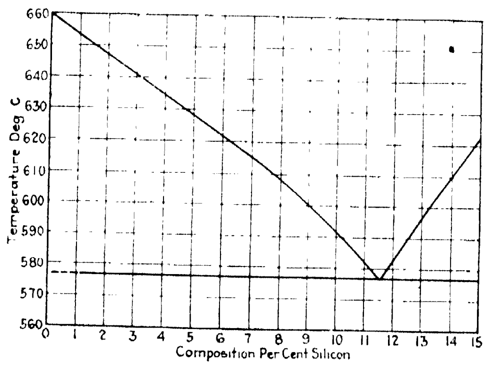

FIG. 2—EQUILIBRIUM DIAGRAM, Al-Si ALLOYS

silicon. As previously noted[4] the presence of a modifying agent will change the eutectic composition and temperature in a very significant manner.

Thermal Expansivity of Aluminum-Silicon Alloys

Data on the thermal expansivity of aluminum are quite well known, but there are only a few measurements available on silicon, and they are at temperatures below 100 deg. C. For comparison, two of these values are given in Table V.

TABLE V—THERMAL EXPANSIVITIES OF ALUMINUM AND SILICON

Metal	Temperature Deg. C.	Expansivity $\frac{\Delta l}{l_0}$	Authority
Aluminum	40	0.0000229	Bureau of Standards (1921)
Silicon	40	0.0000076	Fizeau (1869)

There may be some question as to the purity of the silicon tested by Fizeau, but the data as they stand indicate that silicon has only about one-third the ex-

[11] J. Chem. Soc., vol. 105, p. 1,383 (1914).

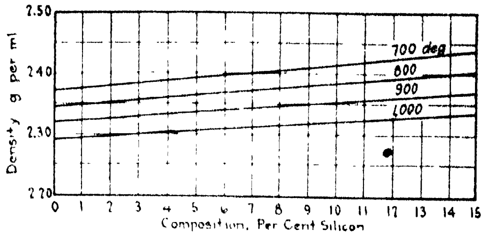

FIG. 3—DENSITY OF ALUMINUM-SILICON ALLOYS AT ELEVATED TEMPERATURES

pansivity of aluminum. This fact is reflected in the expansivities of the aluminum-silicon alloys. The average linear expansion coefficient of the sample of relatively pure aluminum quoted in Table II, between 20 and 200 deg. C., is calculated as 24.8×10^{-6}. This value agrees with that calculated from the expansion formula published by the Bureau of Standards—namely 24.8×10^{-6}. The expansivity of the eutectic alloy (11.63 per cent silicon) as calculated from the density measurements at 20 and 200 deg. C. is 22.2×10^{-6}, which is about 10 per cent less than the expansivity of aluminum. No great confidence can be placed in this value unless supported by other evidence, as a small error in the density measurements—say 0.1 per cent, for example—would make a difference of about 8 per cent in the expansivity. However, other unpublished information makes it appear that this value is correct to within 3 per cent.

The average expansion coefficient of the eutectic alloy between 20 and 577 deg. C., as determined from measurements of total solid shrinkage, is approximately 23.5×10^{-6}, while that of aluminum over the same range is about 29×10^{-6}. It seems demonstrated, therefore, that the linear expansion of the aluminum-silicon alloys is appreciably less than that of aluminum.

Solid and Crystallization Shrinkage of Aluminum-Silicon Alloys

The solid shrinkage and crystallization shrinkage are important factors in determining the casting qualities of an alloy. The crystallization shrinkage is the percentage change in volume in changing from a liquid at the freezing point to a solid at the melting point. In Fig. 4 are shown the complete density curves for pure aluminum (99.75 per cent aluminum) and the 7.81 and 11.63 per cent silicon alloys. The construction of such curves was described in detail in the article on the freezing phenomena of the copper-aluminum alloys.

The most striking characteristic of these curves is that, although the solid aluminum-silicon alloys are

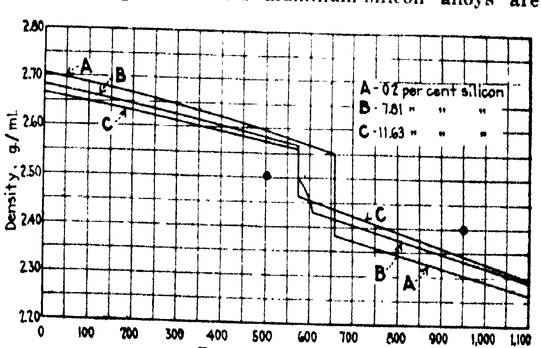

FIG. 4—TEMPERATURE-DENSITY CURVES FOR THREE ALLOYS

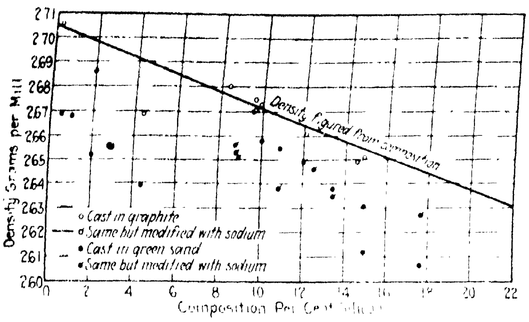

FIG. 1 DENSITY OF ALUMINUM SILICON ALLOYS AT 20 DEG. C

According to Richards,[7] the density of silicon at 20 deg. C. is 2.42. The density of aluminum of the purity used in making these alloys is about 2.705

The density curve of the alloys, calculated on the basis of such a linear relation between the specific volumes, is represented by the solid line in Fig. 1. The specimens cast in graphite, and having presumably the lowest porosity, are closely grouped along this graph. The densities of the sand-cast specimens containing approximately 2 and 4 per cent silicon were very much lower than this curve, and even after remelting and casting in graphite were still below the curve. The question arises as to whether the large variations in density observed with alloys of practically the same composition are caused by structural changes or are merely the result of variations in porosity. The density of the samples modified by the addition of a very small amount of alkali metal is slightly lowered. However, the lowest densities are not characteristic of the greatest grain refinement. The lowest densities are observed in the sand-cast specimens, whereas the greatest grain refinement is secured in the modified alloys chill cast. This would seem to indicate large variations in "porosity" of some kind. However, practical experience has demonstrated that aluminum-silicon alloys are unusual in their lack of permeability to liquids so that pore spaces if present must be isolated and small.

Frilley[8] has recorded a series of measurements on the density of the aluminum-silicon alloys. His data on the 10 and 20 per cent silicon alloys are about 5 per cent lower than the values given in the present paper. The reasons for these low results are not apparent.

Density of Solid Aluminum-Silicon Alloys at Higher Temperatures

In order to complete the density curves up to the melting point, the densities of two representative normal alloys were determined at temperatures of 200 deg. C. and 563 deg. C. These determinations also permitted an approximate calculation of the expansivity. Density at the lower temperature was determined by weighing the sample in air and when immersed in Crisco at a temperature of 200 deg. C. The density of the Crisco was determined at the same time as the weighing of the alloy by means of a platinum cylinder whose volume was accurately known.

A slow change in composition of the Crisco at this temperature made it difficult to secure an accuracy greater than 0.2 per cent. A new sample of Crisco was used for each series of measurements, and its density was checked by repeated weighings of the platinum cylinder.

Weighings at 563 deg. C. were made in a fused mixture of lithium and potassium sulphates. According to Nacken, quoted in Landolt Bornstein Tabellen, there is a eutectic mixture of these two salts which freezes at 535 deg. C. and contains 20 mol per cent of potassium sulphate. I used a mixture containing about 25 weight per cent of potassium sulphate, and found it quite satisfactory, although the freezing point of the salt (about 540 deg. C.) and the melting point of the aluminum-silicon eutectic (577 deg. C.) gave only a very small temperature range to work in, and made the measurements tedious and difficult

Density of Liquid Aluminum-Silicon Alloys

The graphite densimeter was used for determining the density of the liquid alloys. The density of relatively pure aluminum is known from the previous measurements referred to, and the effect of the addition of 8 and 12 per cent silicon was observed in the present series. Results are given in Table III.

These alloys were all normal alloys. The modified alloys, strictly speaking, exist only in the solid state, because the modification is a structural change taking place during the crystallization of the liquid. A liquid alloy with alkali metal added has only the potential property of becoming a modified alloy.

TABLE III—DENSITY OF LIQUID ALUMINUM-SILICON ALLOYS

Composition Si Per Cent	Fe Per Cent	Cu Per Cent	Al Per Cent	Temperature Deg C	Density g ml
7 81	0 39	0 12	91 68	663	2 413
7 81	0 39	0 12	91 68	802	2 375
7 81	0 39	0 12	91 68	904	2 345
11 63	0 45	0 11	87 81	643	2 441
11 63	0 45	0 11	87 81	801	2 392
11 63	0 45	0 11	87 81	904	2.356

A graph of these results indicates the expansion of the liquid alloy to be practically linear from the melting point to at least 1,000 deg. C., and the greatest deviation from a straight line fitted to the data is less than 0.1 per cent. In Table IV are given convenient values for these alloys as taken from the plotted graphs. Fig. 2 shows the freezing points of the aluminum-silicon

it freezes over a considerable range of temperature. Examination of ingots cast from 7.8 and 11.6 per cent silicon alloys showed that the 7.8 per cent alloy, which has a freezing range of 608 to 577 deg. C., showed the rounded edges and small piped cavity characteristic of the 8 per cent aluminum-copper alloy. The eutectic silicon alloy, however, had a more pronounced pipe than the 7.8 per cent alloy, even though its crystallization shrinkage was less. This difference in appearance is illustrated by Fig. 5. A 10 per cent silicon alloy might therefore be expected to have somewhat better casting qualities than a 12 per cent alloy.

The liability to segregation will probably be lower in the silicon alloys than in the copper alloy, because the densities of solid and liquid during freezing are very much closer together than in the case of the copper alloy. Some estimates on the 8 per cent silicon alloy showed that the densities of solid and liquid in equilibrium during freezing never differed by more than 5 per cent.

Ethylene Glycol: Its Uses and Properties

Some Interesting Fields of Usefulness for a Distinctly New and Unusual Solvent, Reagent and Preservative

BY G. O. CURME, JR., AND C. O. YOUNG
Carbide & Carbon Chemicals Corporation

IT is a point of interest that the organic chemical compounds which have had the greatest individual value to the chemical industries, as well as to the public at large, have been those classified chemically as members of the alcohol series. In particular ethyl alcohol, in its legitimate uses, and glycerine have found countless applications and are almost indispensable to the requirements of everyday life. To the rather limited number of such commonly available compounds there has been added, through recent commercial developments, the substance ethylene glycol, a solvent, reagent and preservative of unusual properties.

Ethylene glycol is a pure chemical substance, corresponding to the formula $C_2H_4(OH)_2$. It is a dihydric alcohol, of composition intermediate between that of glycerine and ethyl alcohol, and possesses valuable properties of both these important chemicals, as well as characteristic properties of its own. The pure ethylene glycol on the market is a water-white liquid (sp.gr., 1.116), without odor, possessing a pleasantly sweet taste. It is non-volatile (b.p., 198 deg. C.) at ordinary temperatures, and on exposure to the air it does not evaporate, but attracts moisture, thus giving it valuable moistening properties. It has a low freezing point, and furthermore serves well to lower the freezing point of water solutions; in moderate concentrations, it prevents freezing below the coldest winter temperatures.

As a solvent, ethylene glycol has many of the characteristics of ethyl alcohol and is an efficient solvent for many classes of compounds, such as esters, medicaments, resins, flavors and dyes. It is, of course, miscible with water in all proportions and also with ethyl alcohol and many other organic solvents. It has none of the intoxicating properties of ethyl alcohol; indeed, it appears to be quite harmless when taken internally, even in large amounts.

In view of the large uses for ethylene glycol which are possible in the foodstuff and pharmaceutical fields, research has been carried out to establish definitely its physiological action[1] as well as the bactericidal effects expected from its similarity to ethyl alcohol. Ethylene glycol has been demonstrated to be innocuous on the animal economy. Doses of considerable magnitude, continued for many weeks, produced no outward manifestation on test animals (rabbits). On autopsy, these animals showed no abnormal reactions or changes. From the results obtained it is apparent that this substance can be used without apprehension in the compounding of products for internal consumption.

In tests run in parallel with ethyl alcohol and glycerine, ethylene glycol has been shown to have marked preservative properties against standard cultures of bacteria. Ethylene glycol showed some inhibition at a 10 per cent concentration and was completely disinfectant at 20 per cent concentration. In these tests ethylene glycol showed a close approach to the bactericidal power of ethyl alcohol and to double that of glycerine.

In a commercial sense, ethylene glycol is so new to the chemical industries that the full number of its uses has not been standardized. New applications are being made continuously with good success, showing that in time it will take its place as a standard material in the same industrial class with ethyl alcohol and glycerine, not as a substitute, but as a pure material with irreplaceable properties of its own.

USES IN FOODS AND MEDICINES

Ethylene gylcol is a high-grade solvent and preservative for use in the manufacture of concentrated fruit flavors, fountain supplies and flavoring extracts. It also has much to recommend it as an ingredient in the compounding of food pastes, canned goods, ketchups, mincemeats, salad dressings and other commodities of like consistency. Flavoring extracts with glycol as the vehicle are considerably brighter in appearance, with less tendency toward turbidity, than similar products in which glycerine is used.

In the drug and medicine field ethylene glycol will be found to be a valuable solvent and preservative in liquid products wherein it is the desire to reduce or entirely eliminate ethyl alcohol. Its properties make it a much more desirable substance than glycerine, the preservative action of which is not uniform. Being much less viscous than glycerine, ethylene glycol alters but slightly the original character and consistency of the product, which thus retains the same appearance as when ethyl alcohol is used as the solvent and preservative. In many cases, too, the lower volatility of ethylene glycol makes it preferable to ethyl alcohol in compounding preparations which are apt to suffer from drying out due to loss of the alcohol. Toilet preparations and cosmetics which have combined antiseptic and emollient properties, such as facial creams, may also use glycol with success.

USEFUL MOISTENING AND ANTI-FREEZING PROPERTIES

The combined preservative and moistening characteristics of ethylene glycol recommend it for a wide number of uses, including the manufacture of many cosmetics, the preparation of anatomical and biological specimens, the treatment of skins and furs by the taxidermist, the moistening of tobacco and similar instances where a non-volatile material free from

[1]The discussion of the physiological action of ethylene glycol in this paper has been taken from a private communication from H. C. Fuller, which will be published in full detail at a later date.

injurious action or unpleasant taste or odor is required. For moistening smoking tobacco, especially, ethylene glycol possesses a distinct advantage in that no sharp, disagreeable products are formed upon burning, as is the case with a number of the moistening agents now used.

To the textile and leather industries ethylene glycol offers possibilities as an aid in the finishing and dyeing of fabrics and as a means of preserving the suppleness and flexibility of leather during processing.

The advantageous freezing-point depression which ethylene glycol shows in water solution again makes it valuable for use in preparation of extracts, medicines and toilet preparations and for industrial purposes such as lowering the freezing point of cooling water in automobiles and airplane radiators, exposed dashpots, gages, etc. In this latter connection, glycol solutions of different concentrations have been found to remain fluid at the following temperatures:

Concentration Per Cent of Ethylene Glycol	Safe Limit of Use, Deg. F
10	+14
15	[illegible]
22	[illegible]
30	-22
40	-38

As in the cases where denatured alcohol, glycerine or other anti-freezing mixtures are used, water solutions of ethylene glycol freeze over a range of several degrees as the temperature drops. Complete solidification, which results in damage to the radiator or water jacket, does not occur until a temperature considerably lower than that given in the above table is reached. Anti-freezing mixtures composed of ethylene glycol are not so volatile as alcohol solutions and do not lose their concentration through evaporation, nor do they possess the disagreeable odor characteristic of some denatured alcohol used today. As compared with glycerine or glucose, there is a much greater freezing point depression per weight of glycol used, and less tendency to become gummy or to caramelize. Because ethylene glycol is not an electrolyte and is perfectly neutral, there is no corrosion of any parts, even where copper, brass or aluminum are in contact with iron or with one another. Then, too, in effective concentration there is no action on rubber connections.

Ethylene glycol, on account of its low freezing point and lubricating properties, may also be used in gas meters and ice machines and where the use of a petroleum oil lubricant is undesirable.

Possibilities as a Reagent and Raw Material

As a technical reagent ethylene glycol has already found valuable application abroad in the preparation of explosives. Ethylene glycol dinitrate is in some ways superior to nitroglycerine in the manufacture of dynamite, being less sensitive to shock, having greater force in explosion, and, what is most important, constituting a necessary part of a dynamite, not subject to freezing, even in the coldest weather.

Another glycol derivative, glycol diacetate, has been found to be a cellulose ester solvent, comparable with the widely used amyl and butyl acetates. It has the great advantage that it is practically odorless; furthermore, it has a higher boiling point (186 deg. C.), which permits the same effect with less material in prepared cellulose solutions. The solvent properties of glycol diacetate toward organic compounds and dyes suggest also applications similar to those of the glyceryl acetates which are used so frequently in the printing and dyeing of cotton and as solvents in the coloring of pyroxylin plastics.

The commercial production of ethylene glycol comes at a time when the American chemical industry is asserting itself strongly in world competition after the removal of the direct effects of the war. In Europe ethylene glycol is already finding ever-increasing fields of usefulness. Consequently an American source of this material will no doubt be of value to many of our industries and will assist in keeping them in the forefront.

New York City

Manufacture of Varnishes in 1921

Reports made to the Bureau of the Census show a decrease in the volume of business done by the establishments engaged primarily in the manufacture of varnishes, japans and lacquers during the year 1921 as compared with 1919. The total value of products reported for 1921 amounted to \$71,239,000, compared with \$83,632,000 for 1919, a decrease of 14.8 per cent. Of the 222 establishments reported for 1921, 43 were located in New York, 35 in Illinois, 30 in New Jersey, 28 in Ohio, 17 in Pennsylvania, 12 in Missouri, 11 in Massachusetts, 8 each in Indiana and Michigan, 6 in California, 5 in Kentucky, 4 in Connecticut, 3 each in Maryland and Minnesota, 2 each in Maine, Oregon, Rhode Island and Virginia and 1 in Wisconsin.

The decrease in the value of products has been accompanied by decreases in the cost of materials used, and in the amount paid to salaried employees; but the returns show an increase in the average number of wage earners employed and in the amount of wages paid. In May, the month of maximum employment, 4,396 wage earners were reported; and in February, the month of minimum employment, 3,954 the minimum representing 89.9 per cent of the maximum. The average number of wage earners employed during the year was 4,138 as compared with 4,022 in 1919. A classification of the wage earners with reference to the prevailing hours of labor in the establishments in which employed shows that for 2,411, or 58.3 per cent of the total (average) number, the hours per week were between 48 and 54; for 618, or 14.9 per cent, they were 48 per week; and for 777, or 18.8 per cent, they were less than 48 per week; only 332, or 8 per cent, were reported by establishments in which the prevailing hours of labor per week were 54 or more.

The statistics for 1921 and 1919 are summarized in the following statement; the figures for 1921 are preliminary and subject to such change and correction as may be found necessary from a further examination of the original reports.

	1921*	1919*	Per Cent of Decrease†
Number of establishments	222	229	
Persons engaged	6,962	7,385	5 7
Proprietors and firm members	54	72	
Salaried employees	2,770	3,291	15.8
Wages earners (average number)	4,138	4,022	§2 9
Salaries and wages	\$12,888,000	\$12,821,000	§0 5
Salaries	7,027,000	8,253,000	14 9
Wages	5,861,000	4,568,000	§28 3
Paid for contract work	4,400	39,900	89.0
Cost of materials	44,084,000	51,508,000	14 4
Value of products	71,239,000	83,632,000	14 8
Value added by manufacture‡	27,155,000	32,124,000	15 5

* Figures for 1921 do not include establishments reporting products under \$5,000 in value, thus excluding 10 establishments which employed 84 wage earners, and in the aggregate reported products to the value of \$31,060. The figures for 1919, however, include 9 such establishments, which employed 6 wage earners, and reported products to the value of \$20,035.

† Percentages omitted where base is less than 100

‡ Value of products less cost of materials.

§ Denotes increase.

The Low-Temperature Carbonization of Coal

IV—Improved Type of Primary Retort for Low-Temperature Carbonization and Results Obtained Therewith

BY HARRY A. CURTIS AND WALTER J. GELDARD

IN ONE of the previous papers[1] of this series the authors described the various commercial-size retorts for low-temperature carbonization which were built and tested at Irvington, N. J., up to the time when the Clinchfield plant was put into operation. The development work at Irvington was continued, however, for a little more than a year after the Clinchfield plant was started. During this time the most noteworthy large-scale development at Irvington consisted in the construction and testing of a modification of the Clinchfield type of retort. This latest retort, known in the company's records as Retort No. 25, is shown in Figs. 1 and 2. It differed in a number of ways from the Clinchfield type, the most important modifications being as follows:

a. A readily removable cast-iron top on the retort in place of the complete carborundum muffle used at Clinchfield.
b. A regenerative type of heating in place of the recuperative type.
c. The discharge screws placed just below level of retort floor at discharge end instead of at bottom of a vertical chute several feet long.
d. Provisions for greater agitation of the coal during carbonization, through increasing the number of paddles per shaft and through increasing the speed of rotation of the shafts.

Aside from these major differences there were many minor ones, such as gearing the two paddle shafts together; provisions for wider variations in speed of paddle shafts; two pairs of discharge screws in place of one pair, etc.

Retort No. 25 was designed by C. V. McIntyre with, of course, the co-operation of various other members of the company's technical staff. While later experience at Clinchfield has pointed out ways in which to improve Retort No. 25, this retort, nevertheless, represented a very distinct advance in the art of low-temperature carbonization.

COAL FEED

Coal to be carbonized was crushed to pass a ¾-in. screen, weighed, put through a drier and delivered as required to a feed screw hopper. Coal was fed to the retort by a 9-in. screw operated intermittently, the rate of feed being controlled by an electric "flasher" for varying the "on" and "off" periods of the screw. This method of feed control proved far inferior to the Clinchfield type, where the screws are run continuously, their speed being controlled by gear changes.

AGITATION OF COAL IN RETORT

The two paddle shafts were made of steel pipe with the paddles held in place by two bolts per pair of paddles. Provision was made for eighty paddles per shaft, more than twice the number used in the Clinchfield retorts. The paddle shafts carried 34-in. gears at the feed end of the retort, these gears meshing with each other, the left-hand gear being driven by a pinion. A train of gear changes on the pinion drive permitted rotation of paddle shafts at various speeds between 0.43 r.p.m. minimum and 19.55 r.p.m. maximum. A 25-hp. motor was used to drive the paddle shafts.

While there was wider range of possible paddle speeds, the whole mechanism for agitating the coal in Retort No. 25 must be considered as mechanically inferior to the corresponding Clinchfield machinery. The idea of using steel or wrought-iron pipe for paddle shafts is probably a good one, since it is very much cheaper than the cast-steel paddle shafts used at Clinchfield. In Retort No. 25, however, the bearings were poor and it was very difficult to get at the stuffing boxes behind the large gears. It would probably be better to put steel gudgeons in the ends of the pipe and carry the shafts on heavy bearings a foot or so away from the retort end castings. The end thrust on the paddle shafts should be taken care of at the feed end of the retort.

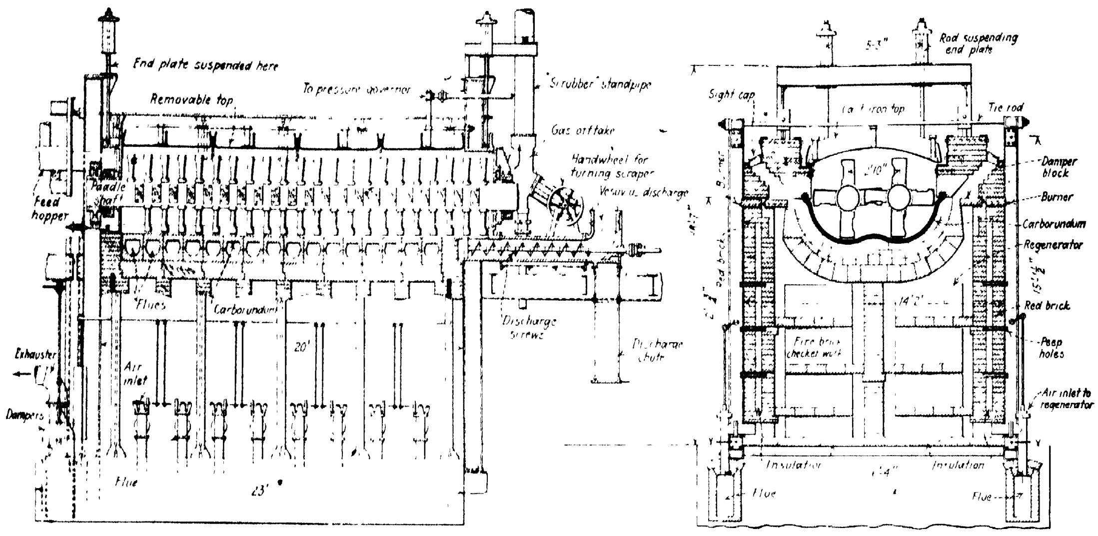
The question as to just how much agitation of the coal is desirable during carbonization has not been clearly settled. It was found, however, that the capacity of Retort No. 25 was very considerably decreased by removing half the paddles—i.e., using only the number of paddles adopted in the Clinchfield type of retort. Since the paddle speed during this test was still nearly twenty times that used at Clinchfield, it is very likely that the agitation of the coal in the Clinchfield retorts is very far below the optimum for high capacity of retort.

REMOVABLE TOP FOR RETORT

This represented a very considerable improvement in Retort No. 25 as compared with the Clinchfield retorts. In the first place, the cost of the cast-iron top is much less than the cost of the carborundum which it replaces. But its big advantage lies in the fact that the time of shut-down required to clean the carbon deposit from the retort wall is greatly reduced. At Clinchfield it requires a minimum of 12 days to cool a retort, clean it out and bring it back into operation. The last time Retort No. 25 was cleaned out the total time of shut-down was 32 hours. When it is considered that a retort must be cleaned once every 60 to 90 days, it will be seen that the removable top is a great advantage. As a minor point the comfort of the workmen cleaning

GAS OFFTAKES, PRIMARY RETORTS

[1] *Chem. & Met.*, vol. 28, No. 1, p. 11, Jan. 3, 1923.



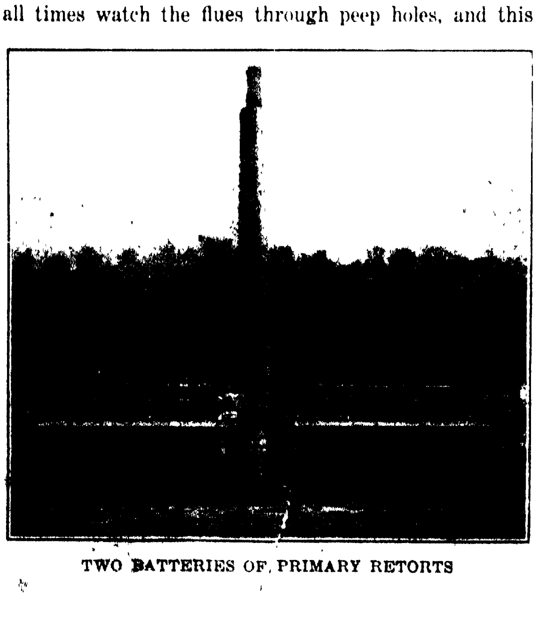
FIGS. 1 AND 2—RETORT NO. 25, A MODIFICATION OF THE CLINCHFIELD TYPE OF RETORT

the retort may be mentioned. The men don't mind how hot it is underfoot when they have head room and plenty of air, but they have to be driven to crawl into a hot retort through a manhole.

Heating System

The heating system on Retort No. 25 was much superior to that used on the Clinchfield retorts. Aside from any increased thermal economy to be secured through use of a regenerator type of furnace in place of a recuperator type, the use of regenerators on Retort No. 25 gave a cheaper furnace. The height of the Clinchfield retort above the foundations is over 25 ft., while the height of Retort No. 25 was only 15 ft. The burners on the Clinchfield retort are located in a tunnel underneath the retort, the flames impinging against the retort near the bottom. These burners are troublesome to operate and the burnerman cannot observe the flues without making a long climb to the top of the retort.

On Retort No. 25 the gas manifolds ran along either side of the retort with the flames passing down the flues and under the retort. The burnerman could at all times watch the flues through peep holes, and this aided very materially in getting good temperature control.



TWO BATTERIES OF PRIMARY RETORTS

Discharge Mechanism

In the Clinchfield type of retort the carbon residue from the retort drops down a vertical chute about 6 ft. long. A pair of breaker arms at the bottom of the chute break up the larger pieces and a pair of overlapping screws carry the material out and force it up over a dam which serves partly to seal the retort. This whole discharge arrangement is a mechanical abomination. The chute serves as a sort of chimney into the retort and the stacking effect of the hot gas therein draws air into the retort unless a relatively heavy gas pressure be carried in the retort. The sealing arrangement at the end of the discharge screws, known as a "Vesuvius" discharge, throws a heavy load on the discharge machinery and causes the gears, pinions and screw flights to wear out rapidly. It operated so poorly that it was eventually abandoned at Clinchfield and the hot carbon residue permitted to fall directly from the screws onto the conveyor belt.

On retort No. 25 the discharge chute and breaker arms were eliminated and the screws moved up to a position just below the floor level of the muffle. Two pairs of discharge screws were used in place of one pair. Unfortunately, the "Vesuvius" discharge at the outer end of the discharge screws was retained. Also there was no means provided for opening the inner end of the discharge screw housing to permit removal of tramp iron which occasionally gets into the retort with the coal and stalls the screws.

While the discharge mechanism of Retort No. 25 represents a considerable advance over the Clinchfield arrangement, it is believed that there is room for much improvement in this mechanism.

Gas Offtake

The gas offtake on Retort No. 25 was almost identical with that on the Clinchfield type of retort. The offtake was at the top of the discharge end casting of the retort. The gas issuing here was passed up through a vertical scrubber standpipe to the foul gas main, with a liquor spray operating in the standpipe. The hand-operated scraper or reamer for the gas offtake as used at Clinchfield was somewhat modified by gearing it to a

hand-operated driving shaft, and a screw thread was cut on the stem of the scraper in order to advance it regularly into the offtake. This scraper worked satisfactorily on Retort No. 25, but a similar installation on the Clinchfield retorts failed completely.

It is thought that the gas offtake and scrubber standpipe could be much improved. There is considerable objection to spraying the foul gas between the pressure governor (Tagliabue at Clinchfield; Smoot on Retort No. 25) and the retort, since the good effect of the governor is partly neutralized by the varying conditions of the spray in the scrubber standpipe.

Operation Data

Retort No. 25 was put under heat in January, 1921. After about 3 weeks' operation, fire destroyed most of the Irvington plant. Repairs were completed by the end of March and several more test runs made in April and May.

It was found very easy to control the temperature on Retort No. 25. Seven thermocouples were located in the retort shell at various points, with one couple in the gas space at the feed end and one couple in the gas space at the discharge end of the retort. With a shell temperature of 1,350 to 1,400 deg. F. (732 to 760 deg. C.) the retort would readily handle 1,700 lb. of coal per hour, reducing the volatile from 35 per cent in the coal to 14 per cent in the carbon residue discharged. Under these conditions the temperature in the gas space in the feed end of the retort was approximately 665 deg. F. and in the discharge end 1,035 deg. F. The retort made approximately 2,650 cu.ft. of gas per ton of coal carbonized, the gas having a calorific value of over 900 B.t.u. and often running as high as 1,000 B.t.u. (light oil vapors not removed). The fuel gas consumption per ton of coal carbonized was approximately 2,250 cu.ft., or about 85 per cent of the gas generated. In battery formation, with better regulation, the fuel gas consumption would no doubt be less.

The tar made was a light, mobile tar of specific gravity about 1.07 at 60 deg. F., the yield being approximately 25 gal. of dry tar per ton of coal.

The following data on one test run of 8 days illustrate the general character of the results obtained in all the tests:

1 Coal used. Pittsburgh Terminal coal (Pennsylvania) 162½ tons (dry)

	Dry Basis
Combustible volatile, per cent	35 3
Fixed carbon, per cent	57.9
Ash, per cent	6.8
Total	100
Sulphur, per cent	1 78
Nitrogen, per cent	1.66
B t.u.	13,925

Coal dried to a moisture of about 1 9 per cent before carbonized

2. Rate of feed, average 1,691 lb. per hour.
3. Retort shell temperature, average 1,392 deg F
   Temperature in gas at feed end, average, 610 deg. F.
   Temperature in gas at discharge end, average, 1,058 deg F
4. Gas made per ton dry coal carbonized, cu ft . . . 2,660
   Average B t.u. . . . 899
   Highest average B t u. for any 24 hr. . . . 1,010
5. Fuel gas used, cu.ft per ton coal carbonized . . . 2 406
6. Dry tar per ton of coal, gal. . . . 24.8
   Specific gravity of dry tar at 60 deg F . . . 1.0783

Distillation of tar: (Sample 2/9/21 to 2/12/21).

Fraction	Per Cent by Volume	Sp.gr. of Fraction	Per Cent Tar Acids in Fraction
0-170° C	2 77	0 8423	21
170-230° C	13.88	0.9235	36
230-270° C.	13 10	0 9828	47
270-300° C.	10.51	1.0071	38
300-310° C.	5 49	1 0193	37
Pitch	54.25	(M.P. 175.3 deg. F.)	

7. Carbon residue, estimated yield, per cent . . . 83.7
   Combustible volatile in dry semi-Carbocal, per cent . . 14.02

The foregoing results are remarkably good for a commercial-size retort. Unfortunately, experimental work at the Irvington plant was discontinued in the spring of 1921. It is planned, however, to rebuild Retort No. 25 eventually, and set it up with the improvements which have been developed during the past year. A test based on several months' continuous operation can then be made.

The New Idea in Trade Association

Equipment Association Differs Essentially From Single-Commodity Group in That Its Major Interest Lies With Equipment Users

By Roberts Everett
Secretary, Chemical Equipment Association

FOR 50 years there have been trade associations in the United States—one or two manufacturers' associations are of that age. Since shortly before the war, and with the increase most of course during the war, there have come into existence about 5,000 American organizations classified as trade and industrial or allied associations until, as an article in a New York newspaper recently said:

> Industry has been wittily compared to the medical profession and to the labor unions. Just as a consulting specialist will examine a patient as far down as the fourth vertebra but no further, and a pipe fitter will fit a pipe but not perform the next operation, so even obscurely small processes or manufacturing groups in industry are limiting themselves in organizations for combined self and public interest.

These associations, almost without exception, are composed of manufacturers of a single product—for example, machine tools, lumber, coal or bread.

The trade association motive and its distinguishing method, as represented by and expressed in these single-commodity organizations, have been and are quite obvious. The motive has been selfish—the promotion of the internal welfare of member companies or of the entire industry of which they are members; and the method, the promotion of those companies' common product as against some competitive product, the obtaining of legislative advantages for themselves as a group, the development of cost-accounting methods for their more intelligent common action, etc.

Searching for the Common Interest

In the last few years, however, a new idea in trade association has found expression. Its origin may be discovered in the equipment fields of a few important industries, and the idea itself is a reflection of an inherent relationship between industrial equipment of any sort and the field or fields in which such equipment is used. This new idea has expressed itself in motives no less selfish than those of the older, more numerous type of trade association; but in its method is its novelty.

Equipment companies, except they are manufacturers of a single item of equipment—for instance, spark plugs for the automobile industry, or ovens for the baking industry, or tanks for chemically based industries—have not among themselves the same things in common as have the manufacturers who, in any single industry, employ the diversified machinery, apparatus and supplies which a representative group of their equipment companies produce. Automobile manufacturers, or wholesale bakers, or dye producers, have identical problems in their separate industries, identical interests

throughout the whole range of their businesses, because the product which they make is common to them all. But what of the companies which produce the manifold equipment that these manufacturers in single industries employ?

Their interests, their problems, their constant concern are not so common. Even in manufacturing, for instance, their problems are not universally alike, for one class of equipment may be based on iron or steel, another on non-ferrous metal, another on wood, another on paper; one may depend on mechanical equipment, another on human craftsmanship; one on plant, another on science. But how about distribution? Only loosely are the selling interests of equipment manufacturers the same. One may distribute his product by registered parcels post; another may require a flat car to move a single item. Then is it cost accounting? No, for costs and cost-finding methods vary with the variety of equipment. Legislation? One equipment producer may depend for his raw material upon a foreign country and is therefore interested in a low tariff; another may require protection to make money. In one association successfully embodying the new idea in trade associations today are members whose "plant" consists of a laboratory, a stenographer and a shipping clerk, and other members whose capitalization runs to $20,000,000 and whose factories and offices dot the entire country.

The New Idea

Obviously, an entire group of equipment manufacturers—or to put it another way the manufacturers of the entire range of equipment essential to the life of any single industry—have just one broad thing in common: *Their direct interest in that industry or group of allied industries which use their equipment.*

So the new idea in trade associations—an idea being successfully exemplified today—comes down to this: To perfect an organization based on common interest not in the promotion of a product common to a group of companies, but in promotion of a group of altogether external industries which bear the relation to the members of the organization of buyer to seller. The equipment manufacturer finds himself directly, abruptly and inescapably affected by the prosperity or poverty, the progressiveness or inertia, the optimism or discouragement of the industries which use his varied but essential products.

The new idea in trade associations reveals itself in equipment organization, as has been said, in method. An equipment association, just as naturally and obviously as does a single-commodity association, seeks primarily the protection of its members' business interests and those interests' advancement. But to find this it must survey the field of the users of the products which its members make; it must not merely "work for the buyer as well as for the seller," it must "work for the buyer because therein only can it work for the seller." To protect its interests and to increase them, it must safeguard its relationships already established with the buyer, and then advance that buyer's business so that the scope of such relationships may likewise widen.

The new idea in trade associations, then, brings the equipment group whose products are at the manufacturing base of an industry or an allied group of industries into the organized democracy of modern industry with a fundamental basis and purpose of constructive good will toward the industries which it supplies. It enlists the equipment group in the active, progressive development of the direct markets to which its equipment goes. It makes the equipment man an active agent in the development of his customers' and his prospective customers' affairs.

Activities of the Equipment Association

What are some of the logical activities of an equipment association? One is market expansion, another is educational market cultivation. Included in the first class is such co-operative work as the Chemical Equipment Association is now undertaking with the government in relation to export markets. Included in it is such clearing to its membership of domestic market information as the Chemical Equipment Association is now performing. Many other phases of market expansion are possible, even reaching to the public as a whole, if necessary.

In the second class may be included all activities which begin or end with a co-operative study of a particular industry's methods of manufacture, its use of equipment, the possibilities of adapting equipment used successfully in one industry to the more economical performance of an allied industry's manufacture, or accordingly, activities that result in better education in the use of equipment. Again using the Chemical Equipment Association as an example, one of its purposes is to "collect and disseminate information as to design, raw material and construction," obviously an activity which calls for co-operation with the industries using the equipment in establishing the most effective designs, construction and raw material possible. Another purpose of the Chemical Equipment Association, as still another example, is to "promote a better knowledge of conditions controlling the industry's development"—surely calling for the highest form of constructive co-operation with the manufacturing industries using chemical equipment.

Both of these classes of activity—market expansion and what is here termed as a very inclusive phrase, educational market cultivation—are premised on the user's needs. They both lead back to palpable, substantial benefits to the equipment group, but only through the latter's having actually engaged itself with the welfare and the needs of the user.

Research work and standardization work are two more logical activities of an equipment group. The Chemical Equipment Association, for instance, has as one of its purposes the standardization of trade phrases. Both these activities imply initial and constant consideration of the user's needs.

Business Ethics

Perhaps most important of all its natural activities is the prevention of trade abuses. One successful equipment association has gone so far as to establish a code of commercial practice which practically affords financial redress to the holders of equipment purchased through misrepresentation. It is true that such a defining of the honorable and the dishonorable in business affords a protection against unscrupulous action to the equipment manufacturer also. But that it protects him as well, in a manner otherwise probably impossible, does not lessen the fact that such activity by the equipment association foremost and signally protects the user.

Publicity—not merely for equipment manufacturers but constructively for the industries which use equipment—the general encouragement of high standards in

the allied using industries, legislative action when such action supports the interests of a using industry—these and still others that can be instanced are logical activities of an equipment association.

Constructive Influence Exerted

In a few industries which have been fortunate enough to develop trade associations at their supply and equipment ends, these associations have won a rapid esteem for the constructive influence they have exerted. An authoritative report to one industry in which such an equipment association exists, an industry in which certain unfortunate conditions prevailed at its inception, has cited that the association "in two short years has done very much to change the general conception of the industry from that of something undignified to something dignified, important and progressive." In another very important industry, the activities of an equipment association through certain standardization work and the adoption of certain general policies of relationship toward the using industry have automatically saved the latter amounts perhaps incalculable over a number of years.

Association Advantages

Nor is it to be concluded, simply because in its method the nature of equipment forces the employment of a new idea, that an equipment association proves negligent in its results to its own members. In return for its constructive interest in the industries which its members supply, those members attract an invaluable good will, an identification that goes beyond the merely commercial. Their association automatically becomes a receiving station of invaluable trade news, of business to be placed, of activities pending, that is cleared to them for immediate and confidential use. Their committees' findings in investigations of trade matters, their officers' contact with government officials and agencies, give its members inevitably informational assets and a prestige of position that brings directly traceable returns.

It has already been demonstrated in a number of fields that the industries using equipment have themselves expanded appreciably through the activities of the equipment trade association. In such expansion, it is only natural that the informational assets and the prestige of position which the members of an equipment organization enjoy give them some advantage in sharing in this new equipment business.

New York City

Manufacture of Cordage and Twine, 1921

The Department of Commerce announces that reports made to the Bureau of the Census show a decrease in the activities of the establishments engaged primarily in the manufacture of cordage and twine during the year 1921 as compared with 1919. The total value of products reported amounted to $74,712,000 in 1921, and to $133,366,000 in 1919, a decrease of 44 per cent.

In addition, rope, cordage and twine to the value of $3,473,000 in 1921 and $9,163,000 in 1919 were reported by manufacturers whose chief products were jute and linen goods. Also, cordage and twine valued at $8,958,000 were reported in 1919 by cotton mills and establishments in other industries; corresponding figures for 1921 are not available at this time.

Legal Notes

By Wellington Gustin

Cancellation Provision Renders Contract Covering Purchase and Sale of Iron and Steel Bars Unenforceable

A little provision crept into an important contract between the Northwestern Bridge & Iron Co. and the Interstate Iron & Steel Co. which the United States Circuit Court of Appeals has held to make the contract unenforceable, and the U. S. Supreme Court upholds this court by denying to the plaintiff a writ of certiorari bringing up the case for further consideration. (278 Federal, 51.)

The Northwestern Bridge & Iron Co. of Milwaukee was a fabricator and erector of structural iron and steel and the Interstate Iron & Steel Co. was a manufacturer of iron and steel, with rolling mills at Marion, Ohio, East Chicago, Ind., and South Chicago, Ill. In March, 1917, they entered into two agreements, one respecting iron bars and the other steel bars. Both agreements were on the regular printed sales contract form of the seller steel company.

The Northwestern Bridge & Iron Co. brought suit on the two agreements for damages for breach by the steel company for failure to manufacture and deliver 200 tons of iron bars and 200 tons of steel bars, less a small amount of each shipped. Before the trial court it obtained a judgment for $35,259.37 damages against the steel company.

Clause Which Rendered Contracts Unenforceable

On the appeal the judgment was assailed upon various grounds, but the one which goes to the root of action is the contention that the contracts are not enforceable because of the clause in the contract reading:

"It is understood that if the tonnages are not specified as called for in this contract they shall be automatically cancelled."

Similar Cases Cited

In the suit the manufacturing seller set up that this provision left it entirely optional with the buyer to take or not to take any or all of the tonnage, and, no consideration appearing for the agreements to sell, neither party became obligated by the contracts. On this question a nnmber of decided cases were cited and the Court of Appeals found that contracts with provisions more or less similar, but involving substantially the same principle, have been held to be unenforceable. In American Cotton Oil vs Kirk, 15 C. C. A., 540 the memorandum of sale of 10,000 bbl. of oil provided "deliveries to be made per week as Kirk & Co. [buyers] desire." Passing on the validity of this contract, the court said:

"Suppose Kirk & Co. had not desired and had not ordered any such quantities as would require 100 years to complete the delivery—is there any way open to the defendant to put plaintiffs in default? We think not, and that there is no mutuality of promises for the sale of a definite or ascertainable quantity of oil."

In Oakland Motor Car Co. vs. Indiana Auto Co., 201 Federal, 499, the agreement was for sale of automo-

biles wherein there were provisions that no order shall be binding unless accepted by the manufacturer at least 30 days prior to date of delivery, and for cancellation by either party for just cause. There was no question, says the court, that the provision for cancellation alone would have rendered the contract unenforceable. But it was contended that the qualification "for just cause" saved the contract from the operation of the rule. The court held that the addition of those words did not exempt the contract from the application of the rule requiring the mutuality of obligation as a necessary element of a binding contract for future sale and delivery.

A provision in a contract of sale requiring the buyer to make periodical specifications of his requirements of products of substantially equal quantities is not a mere formality to be observed or not, but a material provision, and the parties will be held to its observance, especially where the seller is a manufacturer and the articles are of various dimensions, which the manufacturer cannot know until the buyer specifies them.

Where Printed and Written Provisions Are Inconsistent, Latter Prevail

Again, the court says, every part of a written instrument should be given effect so far as possible. But it was urged that in the printed form of the contract there is recited a sale and purchase of the iron and steel bars, and therefore in order to give effect to this part of the contracts they should be held to be sales rather than options to purchase. The rule of law is that where there is irreconcilable difference between formal printed portions of an instrument and other parts of it which are written in the latter will prevail. If the effect of this special clause is to make it optional with the buyer whether he will take any of this tonnage, this is inconsistent with the recited sale and purchase, and the special clause would prevail. The words "buy" and "sell" express a conclusion, and if the things actually agreed upon fall short of making a contract of purchase and sale, then no such contract is effected. Now from the contract it appears that these parties were dealing with something which had no existence and could therefore not be the subject of a present sale, but the subject matter of the contract had first to be manufactured after the buyer made timely requisition therefor as in the contract provided.

Buyer Did Not Specify Tonnages

For over 3 months after the contracts were executed the buyer did not see fit to make any specifications whatever, although the contract provided for substantially equal monthly tonnages during the contract period. The buyer had every reason to believe that the special provision for automatic cancellation operated to cancel each month's tonnage, where no specification was given. The court says it surely could not expect to wait until the end of the contract period, and then, if deemed advantageous, order out the entire 400 tons.

And the provision that if the tonnages were not specified as called for therein, they should be automatically canceled was not a mere provision for the protection of the seller, to be exercised by it or not at its option, especially where another part of the contract provided for cancellation by the seller at its option in case of delay in payment.

Neither did the seller steel company waive its right to set up the invalidity of the contracts because of the provision for automatic cancellation, by disputing the buyer's right under the contract to specify greater widths than 6 in., instead of asserting the invalidity of the contract, or by offering to supply the entire tonnage ordered in lesser widths, it previously having called attention to the provision for automatic cancellation. This claim of waiver of conditions in the contract on the part of the seller arose out of specifications submitted for the steel of greater widths than contemplated under the agreements. The court says the seller might have been willing to supply the full tonnage of the smaller width steels and iron. But this waived nothing, and was merely a proposal to enter into another agreement to supply at the contract prices tonnage which, had the agreements been valid, would at that time have been largely canceled.

Again, there appears no such situation as was present where contracts seemingly somewhat similar have been upheld, such as contracts to supply a buyer's entire season's requirements, to take a manufacturer's entire output, to sell to the buyer alone all the seller may acquire of a particular article for a definite time. But the two contracts in question in this case left the buyer with the unqualified right, and with entire impunity, to cancel the contracted tonnage from month to month until at the end of the time fixed none of it remained; both parties being free to buy or sell elsewhere as they saw fit. Such contracts are in quite a different class from those just mentioned. The latter are unenforceable and hence invalid.

Iron Ore Produced in 1922

The iron ore mined in the United States in 1922, exclusive of ore containing more than 5.5 per cent of manganese, is estimated at 46,963,000 gross tons, an increase of 60 per cent as compared with that mined in 1921. The ore shipped from the mines in 1922 is estimated at 50,046,000 gross tons, valued at $158,222,000, an increase of 88 per cent in quantity and of 76 per cent in value as compared with the figures for 1921. The average value of the ore per gross ton at the mines in 1922 is estimated at $3.16; in 1921 it was $3.37. The stocks of iron ore at the mines, mainly in Michigan and Minnesota, apparently decreased from 13,836,267 gross tons in 1921 to 10,699,000 tons in 1922, or 23 per cent.

These estimates, which are based on preliminary figures furnished by producers of 98 per cent of the normal output of iron ore, were made by Hubert W. Davis, of the United States Geological Survey, Department of the Interior. They show the totals for the principal iron-ore producing states, and, by grouping together certain states, the totals for the Lake Superior district and for groups of southeastern and northeastern states.

Imports and Exports

The imports of iron ore from Jan. 1 to Sept. 21, 1922, amounted to 684,387 gross tons, valued at $2,894,496, or $4.23 a ton. The imports for the year 1921 were 315,768 gross tons, valued at $1,075,909, or $3.41 per ton. The exports of iron ore for the 11 months ended Nov. 30, 1922, amounted to 602,095 tons, valued at $2,770,160, or $4.60 a ton, as compared with exports for the entire year 1921 of 440,106 tons, valued at $2,077,620, or $4.72 a ton. The statistics of imports and exports were compiled from the records of the Bureau of Foreign and Domestic Commerce of the Department of Commerce.

Book Reviews

CHEMICAL ENGINEERING CATALOG. Seventh edition. The Chemical Catalog Co., Inc., New York.

This very useful publication which appears for the seventh year is now almost a standard reference book for chemical engineers. There need be no lengthy descriptive review, as the scope of the book is well-known.

It is a little too top-heavy on laboratory ware with the 65-page catalog of the Will Corporation inserted bodily, but I see no satisfactory solution to that particular problem. The Classified Directory is well made up and extremely useful. In the next edition I would suggest slightly less body to the type in which the subject headings are printed. A more graceful type would make the directory pages easier on the eyes.

The list of scientific and technical books is more complete than in past years and should prove valuable, although the publishers are usually more than generous with catalogs and this is, I should say, the least useful part of the book.

CHARLES WADSWORTH.

VAN NOSTRAND'S CHEMICAL ANNUAL. Edited by *J. C. Olsen*. Fifth issue, thoroughly revised and enlarged, 1922. D. Van Nostrand Co Price, $4 net.

There must be thousands of chemists (I know scores of them personally) who have had occasion to bless this useful book. Especially when one is at some distance from an adequate library where large reference books are available, it is invaluable to have such a compendium. Even with large books at hand, the convenience of using a little book is a big item in its favor. I should therefore conjure the editors not to expand it much further. It is bound to be incomplete, but in its selective incompleteness lies its merit. Keep it small.

To those who know nothing of this book I recommend an introduction by purchase. It will be impossible to discuss the handbook adequately for the complete stranger in a review. As chemist and chemical engineer I have found it a friendly companion and have frequently started on trips with Olsen and a slide rule.

The new edition contains more specific gravity tables, additional vapor tension tables and some table of properties of important elements. These are all sane additions. The specific gravity tables will be especially useful.

It is often a disappointment to find such meager data on solubility, but in all cases checked this has been due to the absence of data and not to any editorial oversight. The establishment of a solubility determination verein seems to be in order. The fifth edition is worthy of its predecessors.

CHARLES WADSWORTH.

Recent Chemical & Metallurgical Patents

American Patents Issued Jan. 9, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be stud'ed later by *Chem. & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,441,203-4-5—Process of Manufacturing Artificial Silk and Other Products From Nitrocellulose. E. Bindschedler and G. Juer; assigned to Tubize Artificial Silk Co., Hopewell, Va.

1,441,206—Guanidine Salts. J. S. Blair and J. M. Braham.

1,441,219—Fertilizer Stock. A. Ehrenreich and Allen Rogers; assigned to Ocean Leather Co, New York

1,441,243—Tanning Liquor From Cellulose Waste Sulphite Lye. A Romer, Stuttgart.

1,441,341—Recovery of Aromatic Compounds. F. X. Govers, New York.

1,441,417—Purification of Hydrocarbons. D F. Gould; assigned to The Barrett Co.

1,441,541—Acetyl Cellulose. W. J. Stevenson, London, England.

1,441,542—Method of Treating Oil-Bearing Shale. H R Straight.

1,441,568—Electrodeposition of Copper. C G. Fink; assigned to Chile Exploration Co

1,441,573. Manufacture of Phosphorus R Franchot and K P McElroy; assigned to Ferro Chemicals Co., Washington, D. C.

1,441,598 Product From Furfural and Process of Manufacture. M. Phillips and G H. Mains, Detroit.

1,441,605—Waterproofing Composition. C D. Shaffer, assigned to Textile Leather & Metal Preserver Co., Kalamazoo, Mich.

1,441,612—Chrome Pigments — Norman Underwood, Oakton, Va.

1,441,655 — Manufacture of o-Sulphonic Acids of Aromatic Amines. F. Boddiley, J. B. Payman and H. Wignall; assigned to British Dyestuffs Corp., England.

1,441,664—Manufacture of Ink. Roy Cross, Kansas City.

1,441,694—Process of Making Fertilizer K P. McElroy; assigned to Ferro Chemicals, Inc., of Washington.

1,441,695—Process of Fixing Nitrogen. K P McElroy; assigned to Ferro Chemicals, Inc, of Washington.

1,441,696—Absorbent for Gases. C. P. McNeil and E P Brown, Whiting, Ind.

1,441,982—Artificial Resins. A. Heinemann, Berlin, Germany

1,441,989 — Production of Cellulose Ethers Leon Lilienfeld, Vienna, Austria.

Complete specifications of any United States patent may be obtained by remitting 10c to the Commissioner of Patents, Washington, D C.

Limekiln — Valentine Arnold, of Woodville, Ohio, has patented certain improvements on a limekiln. These consist substantially in constricting the kiln above the burning zone so as to have it act as a gas choke. This burns the lime more effectively than is possible under the present conditions. The other improvement is the change in shape of the kiln from circular to rectangular below the burning zone. A distinct operating advantage is claimed for this improvement as well as the other. (1,439,597. Dec. 19, 1922.)

Synthesis of Ammonia From Its Elements—T. C. Clancy, of Niagara Falls, N. Y., has assigned to the Nitrogen Corporation of Providence two patents (1,439,291 and 1,439,292), both of which have to do with the preparation of a catalyst which is claimed to be an improvement on his already patented process. The catalyst in brief is made from calcium ferrocyanide by immersing small lumps of pumice about the size of a pea in a solution of pure calcium ferrocyanide, which is sulphur free, etc. The solution is then evaporated to dryness and the lumps of pumice are dried further. Finally, they are put into an autoclave and heated gradually up to a temperature of 350 deg. for a number of hours. As the temperature increases air or oxygen must be excluded from the autoclave, and this is usually done by displacing them with hydrogen and nitrogen. The improvement in the process consists in finally heating the catalyst in the presence of ammonia for a number of hours at a temperature which is somewhat more than 400 deg. but below 650 deg. A catalyst prepared in this way is very much more durable and can be used for upward of 40 days instead of 25 days. (1,439,291 and 1,439,292. Dec. 19, 1922.)

Apparatus for Solvent Recovery—W. K. Lewis and William Green, of Newton, Mass., have developed a process for the recovery of solvents used in applying rubber to belting and other fabric. The patent is much broader than this specific case, however, and the principles may be applied to a large number of processes. The drawings and details of the process are somewhat too complicated for a brief review. Briefly, the solvent is removed from the belting by means of heated flue gases in a closed chamber. The advantage of using flue gases here is that it eliminates the use of air, with which benzol particularly forms a very explosive mixture. The flue gases and benzol vapors then are pumped through a tower suitably packed and through which is flowing a stream of heavy hydrocarbon oil, which absorbs the benzol (or gasoline). The flue gases then continue through the cycle, are somewhat preheated first and then passed into the chamber in which the

belting is dried. The solution of benzol (or gasoline) in oil is then pumped through heat exchanges and through a still, which removes the benzol (or gasoline) from the oil, which in turn is returned to the tower for absorbing more solvent. The use of high vacuum, the injection of steam into the still, and the use of the counter-current flow principle throughout the system are among the unique characteristics of the process. (1,437,980. Dec. 5, 1922.)

Process for the Manufacture of Compressed Hydrogen—Georges Claude, of Paris, France, has assigned this patent to L'Air Liquide Société Anonyme pour L'Etude et L'Exploitation des Procédés Georges Claude, of Paris, France. The process consists essentially in compressing hydrogen to from 50 to 300 atmospheres and then absorbing all the other gases which are normally associated with it, such as methane and carbon monoxide, in ether at a temperature of approximately 60 deg. C. Curiously enough, at moderate pressures of 300 atmospheres and at very low temperatures the differential solubility of carbon monoxide and hydrogen is very much greater than it is at ordinary pressures and temperatures. Advantage is taken then of this fact in separating the carbon monoxide from the hydrogen. The other gases have a higher differential and do not present so serious a problem. (1,438,581. Dec. 12, 1922.)

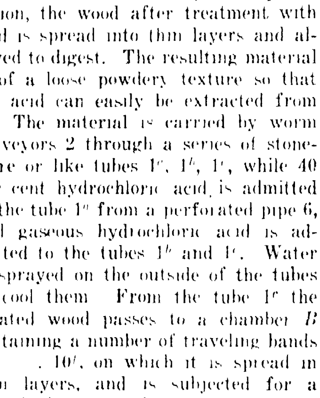
Urea Phosphate—German patent No. 286,491 describes the manufacture of urea phosphate by treating phosphoric acid with urea. Fuller Clarkson and Joseph M. Braham, of Washington, D. C., have attempted to prepare this substance, which is so excellently suited for a fertilizer, by following the specifications given in this patent which recommended adding to about a 50 per cent solution of phosphoric acid the corresponding amount of urea, and heating until all the urea went into solution, filtering and crystallizing. It was found that no crystals could be separated out unless a few crystals of urea phosphate were added to the solution to induce crystallization and that at best the maximum yield obtainable was 31 per cent. The conclusion was that urea phosphate cannot be made in accordance with the process described in this patent and this led to a series of experiments in which were studied the effect of varying the concentration of the reacting substances, the temperature of the solution and the crystallization temperature. It was found that an acid concentration considerably above 50 per cent is desirable, and further that the exact ratio of concentration of acid and urea in solution is not of great importance. They recommend the use of a 75 per cent solution of phosphoric acid and the addition of equi-molecular amount of urea in solutions. (1,440,056. Dec. 26, 1922.)

Apparatus for Extracting Valuable Material—W. C. Graham, of Denver, Colo., has patented an apparatus in which soluble matter is extracted from such materials as shredded or finely divided sugar beets or like material. The principle of the apparatus is to feed the finely divided material into a hopper with a screen in it and to wash it through the screen and subsequently through a large pipe or conduit by means of a centrifugal pump into a chamber. Here it is packed by the pressure of the pump. The chamber into which the finely divided solid flows is very large and consequently the solvent liquor, water in most cases, would reach a very high concentration during transit. (1,437,801. Dec. 5, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England

Glucose and Dextrine—In the process for obtaining dextrine and glucose from wood by treating it first with liquid and then with gaseous hydrochloric acid as described in the parent specification, the wood after treatment with acid is spread into thin layers and allowed to digest. The resulting material is of a loose powdery texture so that the acid can easily be extracted from it. The material is carried by worm conveyors 2 through a series of stoneware or like tubes 1^a, 1^b, 1^c, while 40 per cent hydrochloric acid is admitted to the tube 1^a from a perforated pipe 6, and gaseous hydrochloric acid is admitted to the tubes 1^b and 1^c. Water is sprayed on the outside of the tubes to cool them. From the tube 1^c the treated wood passes to a chamber B containing a number of traveling bands 10^a . . 10^f, on which it is spread in thin layers, and is subjected for a period of up to 11 hours to a temperature between 12 and 50 deg. C. and a pressure of about 1 cm of mercury. From the chamber B the wood passes to a chamber C containing a number of heated hollow floors 15^a . . . 15^g. The odd floors 15^a, 15^c, etc., are of greater diameter than the even floors 15^b, 15^d, etc., and are formed with central openings 18. The material is carried over the floors by scrapers 21 carried by arms 20 on a central shaft 22 and passes through the openings 18 and over the edges of the floors 15^b, etc. The temperature is maintained at 15 to 30 deg. C. and the evaporated hydrochloric acid gas is removed, compressed and re-used. The material passes into another chamber similar to the chamber C but maintained at a temperature of about 50 deg. C. and a pressure below atmospheric. The vapors are passed through a washing vessel, so that the liquid and gaseous hydrochloric acid used are recovered in nearly their original forms. The treated wood is boiled in water and the resulting solution filtered, neutralized and concentrated or fermented. (Br. Pat. 186,139. H. Terrisse and M. Levy, Geneva. Nov. 15, 1922.)



Centrifugal Machine—In apparatus of the type in which centrifugal force is used to drive washing liquid from the periphery to the axis of the separator through separated solid matter by the provision of a peripheral annular space to which the washing liquid is conveyed by passages from the axis of the separator, filtering material is carried by ribs or the like provided on the inner surface of the separator casing. The washing liquid is

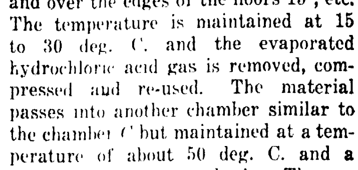


FIG. 1 FIG 2

supplied through a funnel i, Fig. 1, and is forced centrifugally through passages or pipes d into an annular space formed between the outer periphery b of the separator and a filtering cloth c or other filtering material carried on ribs or the like on the periphery. The washing liquid then passes inward through the separated solid g and escapes at the overflow h. Various openings may be provided in the top cover to provide different outlets and thereby variable thicknesses of separated material. Perforated annular pipes or conduits may take the place of the ribs on the outer wall. After washing, the separated material may be projected in a dry state while the machine is running through an opening f, Fig 2, normally closed by a valve k actuated by a handle y through a sliding sleeve w, bell crank levers v and rods u. (Br. Pat. 187,429. Chemische Fabrik Griesheim-Elektron, Frankfurt-on-Main, and F. Sander, Griesheim-on-Main. Dec. 13, 1922.)

Ink—Printing-ink is made by treating waste sulphite-cellulose lyes with nitric acid and a catalyst, preferably metallic copper or zinc, the product being used with coloring matters such as prussian blue and cinnabar, or being treated with sulphuric acid before the first reaction is completed to produce a black ink. (Br. Pat. 187,537. K. J. Smidt, Copenhagen, and R. Jaeger, Berlin. Dec. 13, 1922.)

Arsenic Investigation Report Predicts Shortage

Government Bureaus Believe Urgent Demands Will Be Met and That Conservation Will Relieve Future Shortage

WHILE calcium arsenate supplies will not be entirely adequate for the requirements of 1923, supplies of white arsenic will be diverted from the manufacture of lead arsenate and from the manufacture of glass, thereby making available supplies sufficient to meet the more urgent demands. This is the purport of the report made jointly by the Bureau of Entomology and the Geological Survey in response to a Senate resolution. B. R. Coad, of the former, and G. F. Loughlin, of the latter bureau, are the authors of the report. They point out that there is an apparent shortage of about 5,000 tons of white arsenic in the supplies needed prior to May 1. It is admitted, however, that this shortage may be decreased by importations and by increases in production.

Industry Lacks Stability

There is great need, the report shows, for stabilizing the arsenic industry. It is apparent that the sources of supply are adequate and it is predicted that there will be sufficient white arsenic produced to meet the requirements of 1924 and subsequent years, provided the market can be kept sufficiently stable to encourage producers. Rapid increases in the demand for calcium arsenate may be expected, declares the report, "as the use of calcium arsenate as an insecticide has emerged from experimental stage"

Dr. Coad was given access to the books of the American Smelting & Refining Co., and of the United States Smelting, Refining & Mining Co. He has verified the statement of those companies that practically all of their output has been sold directly to the consumers and that their entire output until June 1 is under contract. The contract price for the material is around 9 cents per pound. The Anaconda Company also contracted for its output last October, so that the principal domestic producers, the report says, "are, therefore, unable to take advantage of the high prices (15 to 17 cents per pound in December, 1922) for any appreciable quantity of white arsenic. The conclusion is obvious that any recent speculation in white arsenic has been with imported material." Even in the case of foreign arsenic, it was admitted that such speculation as was discovered involves only extremely small amounts. No stock is taken in the rumors that large amounts of white arsenic are being held to influence the price.

With the view of stabilizing the arsenic industry, a co-operative study by the Geological Survey, the Bureau of Mines, the Bureau of Chemistry and and the Bureau of Entomology "of the appearance and supplies of arsenical ores, their reduction and the manufacture and use of arsenic compounds" is suggested in the report. Reference also is made to the benefits which will follow concerted action among producers, manufacturers and consumers.

The shortage of 1922 was brought about by the sudden slump in the demand for this material in 1921. The decline in the price of cotton made it impossible for the Southern farmers to buy Apparently the manufacturers did not foresee the possibilities of heavy purchases in 1922. As a result prices reached a point early in 1922 where manufacturers were discouraged from adding to their stocks, which were unusually large at the beginning of 1922.

Early last year, the report points out, there was 8,000,000 lb. of calcium arsenate in warehouse storage. Southern banks, convinced that calcium arsenate had passed the experimental stage, were liberal in financing purchases and as a result stocks soon were exhausted. Altogether about 16,000,000 lb. of calcium arsenate was sold in 1922, without satisfying the demand.

It was not until the fall of 1922 that prices for white arsenic were high enough to stimulate production. The steady increase in production which began in 1914 was offset in part by a decline in imports. A part of that increase undoubtedly was due to war demands. The present demand for white arsenic is estimated by the Geological Survey to be 12,000 tons a year. The capacity of the white arsenic refineries is 18,000 tons annually. The Geological Survey also estimates that at least 25,000 tons could be saved each year as a byproduct in the smelting or arsenical ores in the Western states.

The present minimum annual demand for white arsenic is itemized by Dr. Coad as follows: Calcium arsenate, 3,500 tons; glass, 2,000 tons; lead arsenate, 2,000 tons; weed killers, 1,500 tons; paris green, 1,200 tons; dips, 1,000 tons; proprietary mixtures, 750 tons.

Ford Would Make Calcium Arsenate

That Henry Ford has under consideration the possibility of manufacturing calcium arsenate at Muscle Shoals, in case he should obtain rights there, was revealed in the course of debate in the House of Representatives on Jan. 16. Representative Wright of Georgia declared that the Detroit manufacturer is investigating to see if the manufacture of calcium arsenate cannot go hand in hand with the fixation of nitrogen.

Mr. Wright expressed the belief that "practically every big industry and financial concern in the United States is fighting the Ford offer." This led Representative Garner, the ranking member on the Ways and Means Committee, to suggest that the President himself is the most powerful opponent among those who have arrayed themselves against the Ford Muscle Shoals proposition.

Representative Hull of Iowa entered the debate to state that he is opposed to the Ford offer because Mr. Ford is insisting that Congress do an immoral act in proposing that it award to him something which the government does not own—the Gorgas steam plant.

Executive Order May Adjust Wage Scale of Federal Employees

An executive order may have to be issued to provide an adequate scale of salaries for professional positions in the government service. Congress has wrestled with this question for more than two years, and now as the session is about to close, the reclassification legislation seems to be jammed hopelessly. It is just possible that Congress, on learning that the President is prepared to meet this situation by an executive order, may compromise its differences and provide the long-needed legislation.

If an executive order is issued, it is believed the scale would be about as follows: Chief professional, $7,500 and up; full professional, $5,700 to $7,500; associate professional, $4,500 to $5,700; assistant professional, $2,460 to $4,500; junior professional, $1,860 to $2,460.

Ceramic Society Plans Comprehensive Program

Symposia on Burning and on Consumers' Problems, With Question Boxes to Bring Out Valuable Discussion

For the silver jubilee convention of the American Ceramic Society, Pittsburgh, Feb. 12 to 16, the refractories division has prepared an exceptionally valuable program. General papers on various phases of the industry will be supplemented by sessions on burning and on consumers' problems. The question boxes, which have been found so helpful at recent meetings of the division, are designed to bring out discussion on important points which are not covered by the papers. The program of this division—and of the other divisions of the society as well—will be presented at the Fort Pitt Hotel, Pittsburgh, Tuesday and Wednesday, Feb. 13 and 14.

Following is the program:

SESSION ON CONSUMERS' PROBLEMS

1. Refractory Requirements for Stokers, George I. Bouton, Murphy Iron Works.
2. Refractories From Consumer's Standpoint in the Gray Iron Foundry Air Furnace, R. F. Harrington, Hunt-Spiller Manufacturing Corp.
3. Metallurgical Requirements of Refractories in Copper Smelting and Refining, Francis R. Pyne, U. S. Metals Refining Co.
4. Refractory Requirements for Oil Refining, Alan G. Wikoff, *Chemical & Metallurgical Engineering*.
5. Refractories in Malleable Iron Furnaces, H. G. Schurecht, U. S. Bureau of Mines.
6. Refractories and the Malleable Iron Plant, A. F. Gorton and Mr. Schwartz, National Malleable Castings Co.
7. Suspended Boiler Arches, J. E. Harlow, M. H. Detrick Co.
8. Metallurgical Requirements of Refractories, D. A. Lyon, U. S. Bureau of Mines.
9. Metallurgical Requirements of Refractories in the Gas Industry, W. H. Fulweiler, United Gas Improvement Co.
10. Metallurgical Requirements for Refractories in the Electrochemic Metallurgy of Zinc, B. M. O'Harra.
11. Metallurgical Requirements for Refractories in the Aluminum Industry, R. J. Anderson.
12. Metallurgical Requirements for Refractories for Furnaces Melting Copper Alloys, H. W. Gillett.

QUESTION BOX ON CONSUMERS' PROBLEMS

1. Is it necessary to inspect 9 in. sizes for dimensions? E. E. Ayars.
2. What specification limits should be considered as reasonable on dimensions of 9 in. fireclay brick? A. F. Greaves-Walker.
3. Will results in practice justify the expenditure and added cost necessary in order to make firebrick mixes from definite percentages of definitely sized clay grains? A. F. Greaves-Walker.
4. Should the softening point specifications on high heat duty firebrick be raised in view of the fact that consumers are gradually increasing temperatures, or should another classification be added with more severe requirements? A. F. Greaves-Walker.
5. Is a serious effort being made by manufacturers of fireclay refractories to produce 9-in. brick of full size standard dimensions? A. F. Greaves-Walker.
6. Is the A.S.T.M. spalling test too severe? If so, what changes are suggested? A. F. Greaves-Walker.
7. What is the effect of TiO_2 in amounts less than 2½ per cent on the fusion point of clay refractories? A. F. Greaves-Walker.
8. What is the best type of refractory brick to use in the side walls of air furnaces? C. E. Bales.
9. Does the use of powdered coal decrease the life of firebrick in malleable iron furnaces? C. E. Bales.
10. What is the cause of rapid failure of firebrick in the open checkerwork baffles of oil-fired boilers, subjected to a temperature of 2,300 deg., and against which the oil flame does not impinge? E. E. Ayars.
11. Is the present fusion point of the well-known brands of flint city refractories lower than it was on the same brands in 1900? A. F. Greaves-Walker.

SESSION ON BURNING

1. Burning Fireclay Refractories, E. H. Gartrell, Ashland Brick Co.
2. Use of Pyrometers in Burning Refractories, R. P. Brown, Brown Instrument Co.
3. Producer Gas for Burning Refractories, W. D. Richardson, Ceramic Engineering Co.
4. Burning Refractories, George A. Balz, Seaboard Refractories Co.
5. Notes on Burning Refractories, With Special Reference to Control of Labor Costs, L. C. Hewitt, LaClede-Christy Clay Products Co.
6. A New Tunnel Kiln, R. H. Miller.
7. Insulation of Periodic Kilns, J. H. Krusen, A. P. Green Fire Brick Co.
8. Burning Silica Brick, F. A. Harvey, U. S. Refractories Corp.
9. Changes in Constitution of Fireclays With Varying Heat-Treatment, A. A. Klein, Norton Co.
10. Discussion of Mr. Klein's Paper to be led by U. S. Bureau of Mines Men.

QUESTION BOX ON BURNING

1. Are Shaker Grates or Hand Stokers Suitable for Obtaining of Cone 20 in a Round Down-Draft Kiln? E. E. Ayars.
2. Is Oil Firing Adaptable to the Round Down-Draft Kiln in the Burning of Refractories at Cones 18 to 20? E. E. Ayars.
3. Is the Coal Consumption Per Thousand Brick at a Given Cone Higher With Low Volatile Coal Than With a High Volatile Coal When Burning Refractories Above Cone 10? A. F. Greaves-Walker.

GENERAL—SPECIFICATIONS, RESOURCES

1. Some Thermal Studies, M. F. Beecher, Norton Co.
2. Analysis of High-Alumina Refractory Products, C. A. Underwood, American Refractories Co.
3. Progress Report on Tests for Firebrick Specifications, R. F. Geller, U. S. Bureau of Standards.
4. Chrome Refractories, J. S. McDowell and H. S. Robertson, Harbison-Walker Refractories Co.
5. Ganister of the Baraboo Range, Dr. W. O. Hotchkiss, University of Wisconsin.
6. Quantitative Status of the Flint Fireclays of Maryland and Kentucky, Prof. W. R. Jillson, Kentucky Geological Survey.
7. The Flint Clay Situation in Pennsylvania, Dr. G. H. Ashley, Pennsylvania Geological Survey.
8. The Flint Clay Situation in Ohio, Wilbur Stout, Ohio Geological Survey.
9. Refractory Possibilities of Some Georgia Clays, Prof. R. T. Stull, U. S. Bureau of Mines.
10. Prospecting for Fireclays, E. W. Hess, Clearfield, Pa.
11. Silica Cement, E. N. McGee, Semet-Solvay Co.
12. Refractory Products of France, R. V. Widemann, Paris, France.
13. The Slag Test, R. M. Howe, Mellon Institute.
14. Resistance of Certain Types of Brick to Action of Slags, R. M. Howe, Mellon Institute.
15. Effect of Certain Gases at Various Temperatures Upon Structure of Refractory Brick, R. M. Howe, Mellon Institute.
16. The Development of Apparatus for the Determination of Heat Transfer Values in Refractories, A. S. Watts and R. M. King, Ohio State University.
17. Some Investigation Concerning the Influence of the Alkalis and Alkali Earths on the Fusion Temperatures of the Different Types of Refractory Clays, A. S. Watts and R. M. King, Ohio State University.
18. British Silica Bricks, W. J. Rees, director of research, University of Sheffield, England.
19. Testing of Refractories, W. J. Rees, director of research, University of Sheffield, England.

QUESTION BOX

1. How close can the volumetric determination of Cr_2O_3 in chrome ore be made to check with the gravimetric determination? C. A. Underwood.
2. Are two precipitations of lime in magnesite sufficient, or should the method requiring one cold and two hot precipitations be employed? C. A. Underwood.
3. Can diaspore, bauxite and spinel be thoroughly decomposed by acid treatment? C. A. Underwood.
4. Does the presence of alkali sulphates interfere with the precipitation of calcium oxalate? C. A. Underwood.

At all convention sessions and social functions, the ladies will have a most cordial welcome, and the local committee has arranged special entertainment for them.

There will be a reception and tea from 4 to 5:30 p.m. Monday, to which the gentlemen are invited. Luncheon at Heinz's on Tuesday will be followed by inspection of this famous plant. A luncheon and theater party will be given on Wednesday.

"Methanol" Officially Adopted for Alcohol Nomenclature

At a recent meeting of the board of governors of the National Wood Chemical Association, a resolution was adopted recommending the universal adoption of the designation "crude methanol" or "refined methanol" in place of the term "wood alcohol." The recommendation, which was broadcast to members of the association, follows:

> The large number of casualties due to drinking liquor containing wood alcohol has for many years directed attention to the necessity of adopting some measures that would remove the danger to human life and surround the use of this product with a greater degree of safety.
>
> One of the most advanced steps in this direction was taken when the American Chemical Society suggested the use of a word which did not contain the word "alcohol" and that the term "methanol" be employed. This term has since been used extensively by many large manufacturers, also by the Forest products Laboratory, the United States Tariff Commission, the Mellon Institute of Industrial Research, and others.
>
> Our association has given the matter due consideration and at a recent meeting of the board of governors adopted a resolution recommending that the term "wood alcohol" be discontinued and the term "crude methanol" or "refined methanol" used hereafter as the case might be. Railroad companies will be requested to make such changes in their classifications and tariffs as they may consider necessary to apply the same rates on shipments of "methanol" as are now published on shipments of wood alcohol, and your co-operation in effecting this change will do much toward accomplishing the desired result.

It is felt that this industrial endorsement of the chemists' recommendation marks a worth while decision.

Eastern Potash Corporation in Hands of Receiver

The Federal Court, New Jersey, has appointed custodial receivers for the Eastern Potash Corporation of New York, in the persons of James Kerney, Trenton, and Joseph H. Quigg, Newark. The company has an authorized capital of $7,500,000, and for some months past has been building a large plant in the Raritan River section of the state, for the manufacture of potash, chemicals and byproducts, utilizing local green sands and marl for raw materials. The new works are said to be practically completed, but have never been placed in operation. The liabilities of the company are stated as $3,000,000, and assets of approximately $1,000,000 in excess of this amount, without available cash. The corporation also owns a controlling interest in the Raritan Refining Co., with plant on the Raritan River, Raritan Township, N. J., and the Eastern Limestone Corporation, with works at McAfee, N. J.

Business Paper Editors Visit Capitol

Hear Durgin on Simplified Practice and Hoover on European Conditions

The National Conference of Business Paper Editors met in Washington on Jan. 15 for the purpose of conferring with Secretary Hoover, visiting the United States Bureau of Standards and conferring with the officials of the Chamber of Commerce of the U. S.

At the offices of the Chamber of Commerce the subjects discussed were the present status of the ship subsidy, the Chamber's referendum on education, and the effect on trade associations of the recent consent decree in the case of the United States vs. Gypsum Industries Association.

SIMPLIFIED PRACTICE

At the Bureau of Standards the members of the Conference were luncheon guests of the technical staff, later visiting the laboratories. One of the features of the afternoon was an illustrated lecture on simplified practice by William A. Durgin, head of the division devoted to that subject.

"Many of our industries—many more of our businesses—believe that we are suffering from too great variety in almost every article of commerce in this country," he said. "Leading men in widely different fields agree that the reduction of variety, the simplifying of industrial and commercial practice in any line, will secure some or all of these advantages:

"Simplified practice will decrease stocks, production costs, selling expenses, misunderstandings and all costs to user.

"Simultaneously, simplified practice will increase turnover, stability of employment, promptness of delivery, foreign commerce, quality of product, profit to producer, distributor and user."

Secretary Hoover has established the Division of Simplified Practice to serve as a centralizing agency in bringing producers, distributors and users together and to support the recommendations of these interests when they shall mutually agree upon simplifications of benefit to all concerned. Any group in any branch—production, distribution or use—can secure the services of the division upon request.

HOOVER ON ECONOMIC PROBLEMS

In the evening the Conference met with Secretary Hoover in the cabinet room in the Willard Hotel and listened to an instructive discussion of domestic and foreign economic and industrial topics of the day.

Industry and commerce in Europe have been hit on the head with a mallet as a result of the French seizure of the Ruhr Valley. It has sent a shiver down America's commercial spine, but it carries no threat of a financial catastrophe. In fact the Franco-German relations constitute the only really sore spot on the world's body politic. Sterling is nearly at par. Italy is showing great progress as are most of the other countries of Europe. Even Russia is improving fundamentally.

The effect of France's action will be felt most in America by the producers of small grains. Our manufacturing industries will not be affected greatly. As a matter of fact, it may stimulate the buying of our products by foreigners, since the drastic action of the French gives rise to some fear that the disturbance may become more general, thereby interfering with deliveries. This may cause buyers abroad to place orders immediately, which otherwise might not go forward for many months.

The situation also tends to accentuate that each nation lost the war from a material point of view. The French are the only ones who have refused to admit that fact. Europe, however, is in a much better position now to stand the shock of the French policy than it would have been a year ago. Great progress has been made throughout Europe, with the exception of France, Germany and Austria, in the matter of social, political and economic stability. The improvement in England is particularly marked and unemployment is 30 per cent less than a year ago.

Important Hydro-Electric Development Under Way in Canada

The pulp and paper interests of Canada have been aroused by the important announcement that a dam is to be built at the Grande Discharge from Lake St. John, Quebec, the headwaters of the Saguenay River, which will ultimately develop a million horse power, and will mark another step toward the realization of a dream on the part of certain Quebec politicians, that the province will eventually be lighted and heated electrically.

The contracts between the Provincial Government and the Quebec Development Co. providing for the carrying out of the project have been signed. The cost of the construction according to expert estimates will reach over $12,000,000. Price Brothers, who are at present increasing the capacity of their pulp mills, have guaranteed to buy $1,600,000 worth of power per year.

Public Meeting Planned in Honor of Pasteur

The evening of Jan. 28 will be devoted to exercises in honor of Louis Pasteur at the Town Hall, New York City. Chemical and medical societies have already held memorial meetings in commemoration of the hundredth anniversary of the birth of the French scientist, but this open meeting is planned especially for the general public. Ambassador Jusserand of France will preside and three or four brief addresses will be made by prominent educators and officials dealing with Pasteur's many activities. No charge will be made for the tickets of admission and they will be sent to the various contributors and societies for distribution.

Explains German Connection of New Potash Firm

Representative States That German Interests Are Not Backing Potash Importing Corporation

German interests are not backing the newly formed Potash Importing Corporation of America, according to an official statement of the company given to the New York *Times* on Jan. 18. The statement said that "neither the German Potash Syndicate nor any other German interests has stock in the Potash Importing Corporation of America; neither can they in any way influence the policy of the new corporation."

A. Vogel, American representative of the German Potash Syndicate, said:

"It has been stated that the German Potash Syndicate was anxious to conclude an agreement with an American corporation in order to avoid taxation at home and that Germany would be seeking another loophole to avoid reparations payments, as it is believed that payments for German potash will be allowed to accumulate in this country. The new agreement does not in any way change the liability of the syndicate to pay its German taxes, nor does the syndicate intend to accumulate dollar accounts in this country on account of the reparations matter, because the syndicate is in no wise involved in the reparations question.

"The chief reason for the syndicate entering into an agreement with the Potash Importing Corporation of America is the fact that I notified the syndicate more than a year ago that I would wish to retire within a reasonable time and that it would be necessary for the syndicate to look out for a successor, preferably in the form of an American corporation. The syndicate, therefore, accepted an offer of the Potash Importing Corporation of America to market and distribute the syndicate's products in the United States from May 1, 1923."

"Radium" Company Cited for Fraudulent Advertising

Advertisements by the Aaban Radium Company, Chicago, Ill., that a product manufactured by it contained radium is the basis of a citation just issued by the Federal Trade Commission.

Based upon a preliminary inquiry, the Federal Trade Commission has reason to believe that this firm's product contains no radio-active material and that its advertisements to that effect are deceptive.

Messrs. Abbott E. Kay and R. T. Nelson, co-partners trading as the Aaban Radium Company, are named in the citation and have been called upon to file an answer and appear at a hearing to be conducted by the Commission. At this hearing witnesses representing both sides will be examined to determine the truth or falsity of the firm's advertisements and thereafter a decision will be reached by the Commission.

Coal Commission Report Disappointing

Brings Out No New Data or Explanation of Price Spread Between Mine and Consumer

In its effort to be absolutely fair and to avoid placing responsibility before the blame is proved, the President's Coal Commission has brought out a report which is certain to be a disappointment to the consumers of coal and to many members of Congress. In the coal trade itself there is a very evident sense of relief. In the average investigation of this kind, it is customary to have some harsh things to say to operators, wholesalers and retailers, even before it has been established that they are guilty.

The Jan. 15 report has all the indications of a desire to avoid expressing conclusions until all the facts can be weighed. As a consequence, it may be predicted that the smaller consumers and a certain element in Congress will feel that the report is colorless and that the commission is not reaching the seat of the trouble. It does not express an opinion as to whether or not current prices are just. It does not say whether or not the miners are receiving a higher rate of wage than the consumers should be called upon to pay. No one is accused of profiteering. The report indicates in a general way something as to the spread between the cost at the mine and the delivery cost of coal, but it gives no clue as to who is responsible. Labor, transportation, over-development, storage and other matters are discussed, but little is said about the business factors in coal. For that reason it is certain that some of the gentlemen on Capitol Hill will conclude that the commission has written "Hamlet" with *Hamlet* left out.

Little New Data in Report

The more constructive thinkers both within and without the industry seem to be agreed that the commission did well in making haste slowly. Even those who are expressing much disappointment with the report are inclined to suspend final judgment as to the possibility of the commission bringing out something concrete at a later date.

A careful analysis of the report shows that there is little material in it which could not have been written on the first day that the commission sat. Nevertheless the presentation of this material is regarded as very valuable because the wide publicity will contribute greatly to the popular understanding of the entire subject. The report must be regarded more as a statement of the problems of the commission than as a contribution to their final solution. Not the shred of new statistical information is contained in the document. From a constructive point of view, this failure is regarded as the most serious because the report as it stands holds out no assistance to the New York conference. An unusual opportunity was offered to get material of a statistical character before that body, but this seems to have been made impossible by the mix-up over the cost forms.

A significant feature of the report is the indication that the commission is not inclined to allow the industry to blame all of its ills on slowness of transportation.

Employees of Commission

In connection with its denial of charges that political patronage is being handed out in the way of clerical positions the commission has issued a personnel statement giving the exact numbers of its employees in the various classifications. It follows:

"The commission's staff as at present constituted includes fifty-six technical employees and ninety-three non-technical employees. The members of the technical staff include: Four engineers, thirty-eight investigators, six assistant investigators, seven examiners, one mineral geographer.

"The non-technical employees include: One secretary, one chief clerk and disbursing officer, one administrative assistant, one confidential clerk, forty statistical clerks, eleven stenographers, eight typists, two comptometer operators, seven clerks, three calculating machine operators, one statistical draftsman, six operatives, one graphotype operator, two file clerks, three apprentices and five messengers.

"No member of the commission has a private secretary or messenger."

Export Statistics to Be Compiled in New York

After a careful study of the manner in which import and export statistics are being collected, Commerce Secretary Hoover has decided to continue to compile those figures in New York. Legislative authority recently was given which enabled the transfer of this statistical work from the Treasury to the Commerce Department. The same law authorized the Secretary of Commerce to consolidate the Bureau of Commerce statistics in New York with the Bureau of Foreign and Domestic Commerce and to transfer the work wholly or in part to Washington.

Since import and export figures must be handled largely during a comparatively few days of the month, the impression long has prevailed that if the work were transferred to the Bureau of the Census in Washington, a large number of employees could be temporarily released from their regular duties to handle that peak. The survey of the situation, however, developed that the work is expedited in New York by the fact that the statistical force has close contact with the collector's office in the New York Custom House.

Figures covering the imports during the last nine days of September and during the month of October are becoming available only at this time. This long delay has been occasioned by the changes of schedules caused by the enactment of a new tariff act and by certain other changes in the classifications.

Rubber Planters Confer With Manufacturers

British Representatives Meet With American Manufacturers in Attempt to Assure Future Supplies

British rubber planters and American rubber manufacturers held meetings in New York last week, for the purpose of seeking some way of adjusting the rubber situation so that a price level equitable to both groups may be arranged.

The British planters, Sir Stanley Bois, Eric P. Miller and B. J. Burgess, represent the Rubber Association of London, a group of planters controlling 70 per cent of the world's rubber supply. The American manufacturers represent the Rubber Association of America, whose membership is responsible for 70 per cent of the world's rubber consumption.

The American committee is made up of H. Stewart Hotchkiss, vice-president of the United States Rubber Co.; B. G. Work, president of the B. F. Goodrich Co.; William O'Neill, of the General Tire & Rubber Co.; C. W. Litchfield, of the Goodyear Tire & Rubber Co.; F. H. Brown, of Meyer & Brown, Inc.; William B. Pfeiffer, of the Miller Rubber Co., and Horace De Lisser, of the Ajax Rubber Co.

Washington Interested

The Department of Commerce is said to be interested in what the present conference may do. Assistant Secretary of Commerce Houston conferred with the British party Thursday night and returned to Washington.

The work of the conference, which met in the rooms of the Rubber Association in the Fisk Building, New York, began with an exposition to the visitors of the conditions surrounding the rubber manufacturing industry in this country. In their turn the British committee put before the American manufacturers a thorough outline of the situation in England and its colonies.

Complaint Against Jobber Posing as Manufacturer

Whether or not a jobber and wholesaler may rightfully advertise as a manufacturer is the question involved in a complaint issued by the Federal Trade Commission against the American Turpentine Co., a concern trading as the North American Fibre Products Co.

According to the complaint, the Amercan Turpentine Co. is a jobber and wholesaler of paints, varnishes and similiar products, with its principal office in Cleveland, Ohio. The company, it is alleged, resells its commodities under the name of the North American Fibre Products Co., and in the sale thereof advertises that such commodities are manufactured by the company so selling them.

The commission contends that this practice is an unfair method of competition, as it leads the public to believe that the respondent's products are purchased direct from the manufacturer, thereby saving all intermediate profits.

Courses in Cereal Chemistry at Minnesota University

During the first week in January, twenty-four men and women interested in cereal chemistry gathered together for a week of intensive study of wheat and wheat products. The work was given at the University of Minnesota and was in charge of C. H. Bailey. The morning sessions were devoted to lectures and the afternoons to laboratory work.

Dr. Bailey had charge of the work on hydrogen-ion determinations; R. A. Gortner discussed "Colloids and Proteins"; L. S. Palmer, "Wheat in Nutrition"; J. J. Willaman, "Enzymes in Fermentation"; H. K. Hayes, "Wheat Breeding"; E. O. Stakman, "Wheat Diseases"; R. N. Chapman "Wheat and Flour Insect Pests" and A. C. Arny, "Wheat Classification."

The afternoon sessions were devoted to: Viscosity measurements of flour, using the MacMichael viscosimeter; hydrogen-ion determinations of flour; hydrogen-ion determinations of fermenting dough; electrical conductivity measurements of flour.

Applicants for the course were many times the number accepted. The latter were necessarily limited because of lack of laboratory facilities to handle a larger number. This large demand for intensive training is conclusive evidence of the great desire on the part of cereal chemists for fuller information in this particular field of cereal chemistry. Certainly such a course as here outlined could not be better given than at the University of Minnesota, for nowhere, either in the United States or abroad, is more intensive work or more capable research work being done than at this university. The names of Dr. Gortner and Dr. Bailey are at the top of the list of those who are applying the most advanced methods of physical and colloidal chemistry to the solution of fundamental flour and baking problems.

SCIENTIFIC CONTROL IN BAKING

The physical properties of wheat flour seem to revolve largely around the colloid properties of its gluten. The capacity of the gluten to absorb water and to vary largely in its viscosity depend on the hydrogen-ion content of the medium in which it finds itself. This hydrogen-ion content is affected to a greater or less extent by the buffer action of the salts present, notably the phosphates. These buffer effects vary with the wheat flour grade.

Fermentation, so necessary for the production of bread, is an enzymatic process, and the speed with which a fermenting dough reaches the point where it is ready for the oven is largely a function of intensity of the acidity of such dough.

In some of the largest bakeries of this country, the dough fermentation period is under scientific control by following the change in p_H as the fermentation proceeds. When the proper p_H has developed the dough is placed in the oven.

Paper Plant Expansion Keeps Pace With Water-Power Development

As a result of the negotiations recently concluded between the provincial government of Quebec and the new company organized to develop the power resources of Lake St. John and the Saguenay River already in its initial stages, announcement was made at the offices of the Canadian Export Paper Co., Ltd., that Price Brothers & Co., Ltd., for which it acts as export selling distributor, has entered upon a 3-year program of expansion which will ultimately increase its present daily output capacity of 300 to 900 tons of paper, or 280,000 tons a year, thereby setting a new record for Canada.

The initial work of installation is already under way and the program calls for the production of 200 tons a day new output by January, 1924, and 200 tons additional at the beginning of each of the two succeeding years until the maximum is reached. Price Bros. & Co., Ltd., owns or controls about 9,000 square miles of freehold and leasehold timber limits in the valley of the Saguenay River and the Lower St. Lawrence which have been roughly estimated to contain 20,000,000 cords of pulp wood.

Wide Interest Evidenced in Paper Exposition

In the Paper Industries Exposition to be held during the week, April 9 to 14, at Grand Central Palace, New York, while the American Paper and Pulp Association and its related associations are meeting, three main groups will feature the list of exhibits. The first group will cover paper-making machinery and the chemicals entering into the manufacture of paper; the second will be the making of paper itself, and the third the conversion of paper into its various subdivisions in which it reaches the public, such as boxes, twine, and specialties, as well as the large field of distribution to printer and consumer in the form of writing paper and other papers.

The manufacturers of paper mill supplies have been prompt to take advantage of this opportunity to present their equipment to the paper mill executives who will be at the exposition. A large attendance of paper manufacturers and merchants during the week is likely because of the fact that the exposition will be held during the week of the annual conventions of American Paper and Pulp and the National Paper Trade Associations and their affiliated organizations. The manufacturers of beaters, rolls and other similar heavy equipment are already well represented among the exhibitors as are also the chemical supply companies, which sell bleach, colors, and all of the wide range of chemicals entering into the manufacture of paper. The manufacturers of specialties, such as boxes, paper, twine and the like, are included among those who have contracted for exhibit space.

The chief efforts of the exposition management, however, have at the outset been devoted to the securing of educational exhibits for the show. The Forest Products Laboratory, of Madison, Wis., and the Research Laboratory of the United States Forest Service have been invited to present an exhibit. An effort, for instance, is being made to have a special exhibit of the United States Bureau of Standards, which operates its own paper mill at the laboratory in Washington, where tests are made of paper made by different processes from miscellaneous materials.

Plan Complete Study of Fastness of Dyes

Experiments to determine the effects of various dyestuffs upon different textiles are to be undertaken in the near future by the United States Bureau of Standards. Fastness in relation to moisture and light, oxidation and chemical changes under varying conditions are to be studied especially. The experiments will continue some months.

Exporters of textiles in particular are interested in a number of problems regarding the dyes put into their goods which have arisen, accumulating over a course of years. It has been found that a dye which is satisfactory for the domestic trade sometimes fails to maintain its quality on exported fabrics.

The Bureau of Standards has been asked to determine the degree of washing advisable under different conditions; the varying quality and quantity of dyestuff necessary to hold successfully in different mixtures of yarns; to study the problem of fading in mixed colors and generally cover the subject.

It is expected that several trade associations of textile manufacturers will contribute to a fund with which the bureau may carry forward these experiments on a scale larger than that which would be possible with the limited appropriation at its disposal.

Selenium Chloride Used for Activating Carbon

A new and improved method of making a superior grade of purified carbon at moderate cost has been recently invented by Prof. Victor Lenher of the chemistry department of the University of Wisconsin, and patented jointly with the General Electric Co.

The material yielded by the process may be used for various purposes, such as an activated carbon in gas masks, or in the recovery of gasoline from natural gas. As a purifier material it may be employed in the manufacture of dry-cell batteries or for electrodes.

The new process consists of treating charcoal with selenium oxychloride, a solvent for the hydrocarbons, removing the solution, and washing the residue. The product of such a treatment is much purer than the product of other methods, it is said, and possesses great absorptive properties, and may be used more effectively than ordinary activated charcoal for the absorption of gases. Relatively moderate temperatures below 100 deg. C. are used.

New Jersey Chemists Hear Chamot and Herty

Record Attendance Attracted by Highly Practical Topic, "How Shall the Chemist Live?"

"Solving Problems by Means of the Microscope" and "How Shall the Chemist Live?" were the subjects discussed at the January meeting of the New Jersey Chemical Society, at the largest gathering ever held by that organization. Prof. E. M. Chamot of Cornell University, and president of the Technical Photographic and Microscopical Society, recommended the microscope as a short-cut for chemical research. Recourse to that instrument, he declared, will save both time and money, particularly in "solving those problems which arise in that no-man's land lying between physics and chemistry and physics and the biological sciences. By means of some excellent slides, Dr. Chamot demonstrated the advantages of the microscope in examining such things as ancient coins, glazes on porcelain, textiles and furs. It was interesting to note that in the two last named cases, the microscope shows marked difference in the structure of mulberry silk from the domesticated silk worm, wild silk and artificial silk. The characteristic properties of most animal hairs serve as a quick and easy method of determining the sort and nature of any furs.

How Shall the Chemist Live?

It was Dr. Charles H. Herty's discussion of the economic status of the chemist, however, that most strongly appealed to the New Jersey chemical workers. Anything that affects the chemical industry, Dr. Herty declared, is bound to have its reaction on the chemical profession of this country Therefore, the policy of short-sighted executives who have abandoned industrial research can only be regarded as a serious blow to the chemist. After reviewing the various lines of activity open to the chemist in both academic and industrial work, Dr. Herty called attention to the special appeal offered by the synthetic organic chemical industry. Here is an industry with a greater proportion of output per chemist than in any other branch of industry. The greatest enhancement per unit of raw material is directly attributable to the work of the chemist.

American Chemists Should Lead

Dr. Herty warned the leaders in the field of synthetic organic chemistry against being satisfied with simply doing as well as another nation has already done. "This country," he said, "has the right to expect that American chemists, if given the chance, will lead the world in the development of chemical industries, but this can only be accomplished by research work of the highest type by men who dare venture into untrodden fields." Very aptly Dr. Herty applied to the chemical industry that biological truth—"when growth stops, decay sets in." He showed clearly by means of employment figures taken from the Tariff Commission's Census of Dyes and Organic Chemicals that the chemist is keeping pace with his industry. In 1920, 2,406 chemists were employed in the synthetic organic chemical industry to produce 370,000,000 lb. of products. In 1921, 1,561 chemists in this same industry produced but 121,000,000 lb. of products.

In concluding his talk, Dr. Herty called attention to unsound public opinion regarding the chemical industry. He attributed much of this to the chemists' failure to keep the public properly informed. "We have no right," Dr. Herty said, "to keep the laymen in ignorance of what we are doing, and I should like nothing better than to see New Jersey, as the center of the chemical industry of the country, take the lead in helping the people to know what chemistry has to offer."

Make Byproducts Pay to Eliminate Waste

An important step forward in the campaign looking to the elimination of waste in industry is about to be made, Secretary Hoover has intimated. Plans are practically complete for a survey of the lumber industry with the idea of developing the wastes which can be eliminated profitably.

Waste cannot be eliminated, to any important extent, by legislation. If it is to be prevented, it must be made profitable. The contemplated investigation will be made under a co-operative agreement between the Department of Commerce and the lumber industry. It is believed that a systematic and nation-wide study of wastes, by industries, will reveal great opportunities for the utilization of byproducts.

Personal

Thomas M. Bains, Jr., of California has been appointed assistant professor of mining engineering, University of Illinois, Urbana. He will have charge of the coal-washing and ore-dressing laboratory.

H. C. Barlow, formerly of the chemical and metallurgical branch of the Dominion Bureau of Statistics, has returned to his former position as assistant chemist for the Deloro Smelting & Refining Co., Deloro, Ont., having resigned from the bureau.

Robert Gilman Brown has been elected president of the Institution of Mining and Metallurgy, 1923-1924, to succeed S. J. Speak.

Arthur P. Denton has resigned as sales manager, Pacific Portland Cement Co., to become district engineer for the Portland Cement Association, with headquarters at the San Francisco office.

T. A. Dines has been chosen president of the Midwest Refining Co., Denver, to succeed Henry M. Blackmer, who has been made chairman of the board. Mr. Blackmer will continue his active association with the company, leaving the details of the administration of its affairs to Mr. Dines. Mr. Dines has been connected with the Midwest company since 1915, when he was elected treasurer.

Walter F. Graham, who for some time past has been associated with the Henry Souther Engineering Corporation in Hartford, Conn., has resigned to take charge of the foundry operations of the Curtis Bay Ship & Engine Co., Baltimore, Md.

Herbert R. Hanley, formerly of Bakersfield, Calif., has accepted the position of associate professor of metallurgy at the Missouri School of Mines, Rolla, Mo.

Colonel George T. Slade has been elected president of the Tide Water Oil Co., New York, succeeding Robert B. Benson, who has become chairman of the board.

Dr. Julius Stieglitz, director of the department of chemistry, University of Chicago, spoke before the Philadelphia Section of the A.C.S., Jan. 18, on "The Laws of Chemistry Govern the Mechanism of Life."

Robert E. Swain, professor of chemistry at Leland Stanford University, sailed for Europe on Jan. 18. He expects to be gone about 6 months and will visit various countries of continental Europe.

James G. Vail, of the Philadelphia Quartz Co., presented a paper on "Uses of Sodium Silicate" before the Association of Corrugated Paper and Fiber Box Manufacturers, New York City, Jan. 18.

The following men from the University of Chicago will give talks by radio from the Chicago *Daily News* station: Feb. 20, Prof. Julius Stieglitz, on "Chemistry and Medicine"; Feb. 27, Prof. H. I. Schlesinger, on "Radioactivity," and March 6, Prof W. D. Harkins, on "The Structure of Atoms."

The following officers have been elected for the Southeast Texas Section of the A.C.S. for the year 1923: President, L. S. Bushnell; vice-president, W. A. Slater; councilor, F. M. Seibert; treasurer, L. B. Howell, and secretary, P. S. Tilson.

Obituary

Albert H. Miller, chief metallurgist of the Nicetown works of the Midvale Steel & Ordnance Co. and an expert in steel analysis, died Jan. 11, at Ambler, Pa. He was 43 years old. Mr. Miller was a graduate of the University of Pennsylvania and entered the employ of the Midvale company in 1901.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

The Present Trend of Business

Return of Confidence, Higher Prices, Easier Money Conditions and Growing Volume of Manufacture Form Basis of Favorable Prediction*

BY PERCY H. JOHNSTON
President, Chemical National Bank of New York

AN ANALYSIS of the present situation reveals indications that business has entered a period of increased activity and that an appreciation of values in the commodity markets is under way. The fact that confidence in future values has been largely restored is evidenced by the pronounced rise in the price level which has occurred in the past few months in contrast to a continued decline during the preceding year and a half. While difficulties in handling the increased freight traffic by the transportation system have become an important factor in the current industrial situation, yet the railroads are dealing efficiently with the problem and it is not thought that the ill effects of congestion will be more than transitory.

More serious, indeed, is the possible shortage of labor and a resultant rise in the wage scale. It is of significance that in England, with whose products we must compete in the markets of the world, no correspondingly definite rise in commodity prices has yet occurred and instead of an increase in the wage scale, recent reductions have been reported. In fact there is in England considerable unemployment.

INCREASED PURCHASING POWER

Of the forces at work tending to bring about an increased volume of business and higher prices the most important is the enormous supply of credit available for industry and commerce, due primarily to an unprecedented amount of gold at present in the country. The increased cost of production of articles of manufacture, due to a higher wage scale and the enhanced value of raw materials, tends to raise the price of the finished product. Other forces which will tend to effect a rise in commodity values are the increased purchasing power of the wage-earner; the recent tariff law, which increases the price of importations of both raw materials and manufactured products; and finally the speculation which invariably accompanies easy money conditions and a rising commodity market. Increased volume of trading will be accentuated both by the fact that inventories have been well liquidated, and that the ultimate consumer who has deliberately, during the period of falling prices, postponed purchases not of an absolutely necessary nature, will immediately supply his accumulated needs when he is convinced that the market is rising.

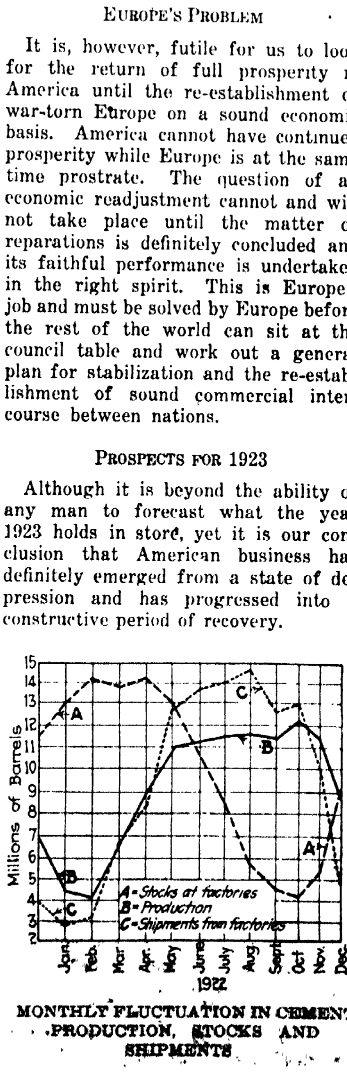
*Extracts from the president's report to the stockholders, Jan. 9, 1923.

EUROPE'S PROBLEM

It is, however, futile for us to look for the return of full prosperity in America until the re-establishment of war-torn Europe on a sound economic basis. America cannot have continued prosperity while Europe is at the same time prostrate. The question of an economic readjustment cannot and will not take place until the matter of reparations is definitely concluded and its faithful performance is undertaken in the right spirit. This is Europe's job and must be solved by Europe before the rest of the world can sit at the council table and work out a general plan for stabilization and the re-establishment of sound commercial intercourse between nations.

PROSPECTS FOR 1923

Although it is beyond the ability of any man to forecast what the year 1923 holds in store, yet it is our conclusion that American business has definitely emerged from a state of depression and has progressed into a constructive period of recovery.



MONTHLY FLUCTUATION IN CEMENT PRODUCTION, STOCKS AND SHIPMENTS

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	174.21
Last week	171.71
January, 1922	144
January, 1921	181
January, 1920	242
April, 1918 (high)	286
April, 1921 (low)	140

A marked rise in this week's index number results from the considerably higher prices for both cottonseed and linseed oils. Slightly lower quotations on caustic soda did not affect the index appreciably.

Record Shipments of Cement Made in 1922

Both Output and Shipments Show Marked Gains Over 1921, According to Geological Survey Figures

During the year just ended the output of finished portland cement is estimated to have reached 113,870,000 bbl., as compared with 98,293,000 bbl. in 1921, a gain of 16 per cent. These figures, which are those of the U. S. Geological survey, are based on actual returns from producers, although lack of reports from four producers made it necessary to estimate figures in their cases.

A total of 116,563,000 bbl. of cement was shipped to consumers throughout the United States during 1922. This represents the heaviest total of shipments recorded in the history of the industry. Shipments during 1921 reached 95,051,000 bbl., or a little over three-quarters of the total for the year just passed.

CEMENT PRODUCTION SHIPMENTS AND STOCKS

	1921 No. of bbl.	1922 No. of bbl.
Production	98,293,000	113,870,000
Shipments	95,051,000	116,563,000
Stocks on hand at end of year	11,938,000	9,134,000

Stocks of finished portland cement at factories, Dec. 31, 1922, amounted to 9,134,000 bbl., or 2,804,000 under the quantity on hand one year ago.

There were also about 2,823,000 bbl. of clinker, or unground cement, at the mills at the end of December, as against 1,949,000 bbl. at the beginning of the month.

As shown in the accompanying table, stocks on hand Dec. 31, 1922, were not only lower than those available Dec. 31, 1921, but shipments exceeded production by nearly 3,000,000 barrels.

Stabilizing Influence Seen in New York Chemical Market

Manufacturers Advance Prices on Acetate of Lead and Hydrofluoric Acid—Potassium Salts Show Strength on Spot

ACTIVITY in the chemical market has been limited to a few special items during the past week and trading in general was of a routine nature. Prices for most chemicals held to their former levels, with a few increases noted, due, it was said, to increased producing costs. The chemical market in general seems to be quite slow in hitting the new year stride and several leading interests are expressing their disappointment at this condition. It is generally believed, however, that the gradual recovery will lead to a completely stabilized market which will show satisfactory results in the long run.

Dealers in arsenic were inclined to offer spot goods at lower prices. Several fair-sized tonnages were reported on dock from Japan. It should be pointed out, however, that the market still retains a very strong position and any pronounced buying activity will tend sharply to advance spot quotations. Producers of acetate of lead announced an increase of 1c. per lb. for all grades. The recent rise in the metal is directly accountable for the new price. Caustic potash is quite firm on the spot market, due to the difficulty experienced in obtaining foreign shipments. Caustic soda for export was a shade easier, although the domestic inquiry continued fairly active. The bichromates showed a slight tendency to strengthen on the spot market and dealers were not anxious to offer any round lots at inside figures. Ammonium nitrate was in very strong demand, with spot stocks completely exhausted. Fluoride of soda, acetate and chlorate of soda, formaldehyde and oxalic acid continued along moderate lines with demand merely of a routine nature.

Principal Price Changes

Acetate of Lead — Producers announced an increase of 1c. per lb. on all grades due to the increase in lead prices. Quotations for white crystals range around 13@13½c. per lb. Demand is quite active.

Acetate of Soda—Several sales were recorded around 6½c. per lb. The general range, however, is around 6¾@7c. A few stressed lots were noted on the spot market and these had a strong tendency to weaken quotations.

Arsenic — Several large shipments from Japan weakened the spot market and jobbers were quite willing to accept business at 15¼c. per lb. Buyers showed no anxiety to pay top figures and actual trading was of a limited nature. The range was around 15¼@15⅜c.

Bichromate of Soda—Small lot trading seemed to feature this market and prices ranged around 7¾@8c. per lb. Round lots were offered down to 7½c.

Bleaching Powder — Producers continue to quote 2c. per lb. for large drums, f.o.b. works in carload lots. Spot goods all in limited supply and dealers quote $2.25 per 100 lb. for odd lots. The demand continues along very active lines.

Carbonate of Potash — A moderate improvement was reported in the calcined and hydrated grades. Offerings were not as plentiful as noted during the past few weeks and inward manifests seem to have decreased considerably. Calcined 80-85 per cent is now quoted at 5¾@6c. per lb. with hydrated at 7c. per lb.

Caustic Potash—Imported 88-92 per cent is reported higher on spot at 7c. per lb. The strong position of the foreign market is keeping prices unusually high. Consuming inquiry continues moderately active.

Caustic Soda—Slightly lower prices for export were announced due to the lack of buying interest. Spot quotations range around $3.45@$3.50 per 100 lb. f.a.s. Domestic inquiry is quite active with contracts quoted at $2.50 per 100 lb., basis 60 per cent f.o.b. works in carload lots.

Chlorate of Soda—Demand continues along routine lines, with domestic makers quoting around 6½@6¾c. per lb. Imported material is being held at the same level.

Cyanide of Soda — Domestic producers continue to quote 23c. per lb for 96-98 per cent goods and report a fair consuming business. Imported material ranges around 19@22c. per lb., according to strength and quantity.

Fluoride of Soda—Activity has been quite limited during the week and prices for imported goods were lower at 9@9½c. per lb. Domestic prices ranged around 10@10½c. per lb.

Formaldehyde Producers continued to quote 16c. per lb. for carload lots and 16½c. for smaller quantities. Demand is somewhat easier due to several second hand offerings around 15¾c. per lb.

Oxalic Acid—Domestic material on spot ranges around 13c. per lb. with imported held at 13¼@13½c. duty paid. Demand has been quite active of late.

Soda Ash—Domestic business was reported quite satisfactory with several carlot transactions at $1.75 per 100 lb. in single bags. Contract business was reported in fair demand at $1.20 per 100 lb., f.o.b. works, basis 48 per cent, single bags, carload quantities.

Linseed Oil—Prices for spot goods were advanced 3c. per gal., due to the higher seed market. Oil in carload quantities, cooperage basis, sold around 90c. per gal. for immediate delivery.

Paint and Varnish Industry in 1921 and 1922

Census Figures for January-June, 1922, Are 1.5 to 50.5 Per Cent More Than in 1921

The first semi-annual statistics of paint and varnish production taken at the request of the industry by the Census Bureau show a marked expansion of these industries during the first half of 1922, thus confirming forecasts made at the November convention of the National Oil, Paint and Varnish Association. The report covers the output in the first 6 months, Jan. 1 to June 30, 1922, with comparisons for the calendar years of 1920 and 1921. The accompanying tabular statement presents the statistics.

The data were compiled from reports from 402 establishments, of which 104 reported the manufacture of white lead in oil; 120 the manufacture of zinc oxide in oil; 228 the manufacture of other paste paints; 337 the manufacture of ready mixed and semipaste paints; and 246 the manufacture of varnishes, japans and lacquers.

The next report will cover the 6 months period ended Dec. 31, 1922, and for comparative purposes the figures for the calendar year will be given, as well as the calendar year figures for 1921 and 1920.

PRODUCTION OF PAINTS AND VARNISHES, 1920, 1921 AND 1922

	1922 Jan 1 to June 30 (6 months) Lb.	1921 (Full Year) Lb.	1920 (Full Year) Lb.	Per Cent of Increase* 1921-1922†	Per Cent of Increase* 1920-1921
Paints:					
Paste paints	207,469,000	382,490,000	343,626,000	8.5	11.3
White lead in oil	138,942,000	273,874,000	209,372,000	1.5	30.8
Zinc oxide in oil	4,341,000	5,770,000	7,946,000	50.5	—27.4
Other paste paints	64,186,000	102,846,000	126,308,000	24.8	—18.6
Ready mixed and semi-paste, including wall paints, "mill whites," and enamels	Gal. 31,159,000	Gal. 44,500,000	Gal. 55,248,000	40.0	—19.5

* A minus sign (—) denotes decrease. † Increase with respect to one-half of 1921.

23,260 for a Dollar

German marks as a medium of international exchange almost dropped off the market Jan. 18 when cable transfers on Berlin fell to $0.000043. This is a new low record, equivalent to 23,260 marks to the American dollar.

The note circulation of the Reichsbank at the end of December, 1922, amounted to 1,200,000,000,000 marks, compared with 754,000,000,000 marks at the beginning of December and 469,000,000,000 at the beginning of November.

Better Volume of Business in Chicago Market

Price Tendency Generally Upward With Fairly Active Trading

CHICAGO, Jan. 18, 1923.

A very good volume of business was reported from practically all divisions of the industrial chemical market. Spot goods were moving well and withdrawals on contracts were quite heavy. Prices held firm, particularly on imported material, where the uncertainty of replacements strengthened the market. The tendency all along the line was upward; buyers apparently realized it and were taking on supplies beyond their immediate requirements.

PRICES WELL MAINTAINED

Alkalis were well maintained in price and were reported as moving in a good volume in the spot market. The ground 76 per cent *caustic soda* was quoted in moderate lots at \$4.25 per 100 lb. and the solid at \$3.50. *Caustic potash* was sharply advanced in the spot market and 8c. per lb. on the 88-92 per cent material was the best offer noted. This advance was not surprising, as the spot price on caustic potash has been below the import cost for some time past. *Soda ash* was in good demand and the price was steady at \$2.25 per 100 lb. basis cooperage.

Potash alum was in fair request and only moderate supplies were available for spot delivery. The iron-free lump was quoted in single cask lots at 4½@5c. per lb. and the powder in similar quantities at 5½@6c. per lb. *Ammonium chloride*, white granular, was in good demand, with the spot price firm at 8@8½c. per lb. It was possible to better these figures slightly on material for shipment from the East. Barium salts were unchanged in price and were in only fair demand. *Barium chloride* was offered in small or moderate lots at \$110 per ton. The *carbonate* was quiet and supplies were available at \$90 per ton. *White arsenic* continued very scarce and high priced with only a few very small lots offered at 17c. per lb. The shortage of arsenic has had an adverse effect on the copper sulphate market and very little of the material is moving. Due to the strength of the metal, however, the price has been maintained at 6c. per lb. for less than carload lots. *Carbon tetrachloride* was firm and unchanged at 10½@11c. per lb. in large drums. *Carbon bisulphide* continued scarce and the spot price was well maintained. The best offer for delivery from stock was 7½c. per lb., but it was possible to do some better on material for shipment from the works. Moderate lots of *formaldehyde* moved to the consuming trade and the price was firm at 17c. per lb. in less than 5-bbl. lots. *Furfural* was available at 25c. per lb. in 1,000-lb. lots and should find a good market if formaldehyde continues to advance. *Glycerine* was quiet and supplies of the c.p material were available in drums at 18@18½c. per lb.

Phosphoric anhydride was in better demand, but the price was unchanged at 40c. per lb. for 1-lb. tins in case lots. *Cyanide of potash* was firm and unchanged at 55c. per lb. *Yellow prussiate of potash* was weaker on spot and supplies were available at 40c. per lb. The *red prussiate of potash* was also weaker and it was possible to do 92c. per lb. in single cask lots.

LINSEED OIL AND TURPENTINE

Buyers were not interested in linseed oil and only small quantities were moving. Boiled oil in single-drum lots was quoted at 96c. per gal. and the raw in similar lots at 94c.

Turpentine was too high priced to be of interest to most buyers and consequently very little moved. Today's price for single drums was \$1.59 per gal.

Steel Market Continues Active

Prices Are Stiffening and Consumption Is at a Higher Rate

PITTSBURGH, Jan. 19, 1923.

The steel market continues at the active rate reached in December, there being very free placing of orders by all classes of buyers, though it is noticeable that the proportion of early delivery business is larger than what might be considered normal. Prices are stiffening, in general, and while it can hardly be said that the whole steel market is in the act of advancing, there is something occurring along that line.

The various steel consuming lines appear to be operating at somewhat better rates than in December.

PRODUCTION AND LABOR SUPPLY

The rate of steel production seems to depend chiefly upon labor supply. The actual physical capacity, between 50,000,000 and 55,000,000 tons of ingots a year, is far above the recent operating rate or any that is likely to be attained. While labor supply has improved somewhat since October, it has not improved as much as might have been predicted on the basis of the season of year, which curtails outdoor work and must release many men. As construction activity promises to be as heavy this spring as last autumn, if not heavier, the steel industry's prospect is that it will have a greater labor shortage next April than it had last October.

Steel ingot production was quite uniform during the last 3 months of the old year at a rate of about 40,000,000 tons a year, representing somewhat more than 75 per cent of capacity. By the end of this month the rate may be 5 per cent better and the high point may represent a gain of 10 per cent, the high point naturally falling in March, always a good month for operation. For later months, much depends on labor supply and something may depend on the pressure of buyers for deliveries, though in general it looks as though the steel industry could run fairly well on momentum to the middle of the year, even should the present buying movement taper off, of which there is no sign thus far.

In most finished steel products there is more or less of a rising tendency. With one exception, conspicuous in consequence, this tendency is seen only in what is frequently called "the independent market," which has sometimes, and particularly in 1920, been an entirely separate institution. The Steel Corporation's general policy, as exemplified by its action last November in continuing its old sheet and tin plate prices, has been to make no advances. Shapes and plates, however, it has advanced this week, from 2c. to 2.10c., while it leaves bars at the old price of 2c. The object seems to be to restore the old differential, which ruled pretty steadily before the war. Among the independents at least bars have really been stronger marketwise than plates or shapes for some time past.

The Cambria Steel Co. started the advancing movement in the heavy rolled steel products late last week, advancing its price on bars, shapes and plates from 2c. to 2.10c., and other independents have been following, practically all being now on a 2.10c. basis. This make the market 2@2.10c. on bars and 2.10c. on shapes and plates. A few independent mills are quoting above 2.10c. on the less desirable plate business.

RISING PRICE TENDENCY

An advance in the independent market in sheets is imminent, several mills having already withdrawn from the market at the old prices. The Steel Corporation could hardly take action in any event, as it is practically sold up on sheets until June. The regular market is 2.50c. on blue annealed, 8.35c. on blacks, 4.35c. on galvanized and 4.70@5c. on automobile sheets. A respectable tonnage of blue annealed, for early delivery, is now going at 2.60c. The prediction is that the independents will advance black and galvanized \$3 a ton, to 3.50c. and 4.50c. respectively. They are all sold for a large part of the current quarter and an advance if made will doubtless carry with it an opening of order books for the second quarter.

Semi-finished steel, including billets, slabs and sheet bars, is strong at its recent advance of \$1 a ton in the minimum, and offerings are scant, the market being quotable at \$37.50@\$38.50.

Pig iron is rather quiet in point of turnover, the quietness attracting some attention. Prices are steady or firm, but are not being very seriously tested, as the inquiry is almost entirely for small prompt lots. The market stands at \$27.50 for bessemer, \$25@\$26 for basic and \$27@\$28 for foundry, f.o.b. valley furnaces.

Connellsville coke has softened a trifle in the week, but shows little sign of receding to its level of early in December, prompt furnace being now at \$8@\$8.25 and prompt foundry at \$9@\$9.25. There is no interest whatever exhibited in the matter of second quarter contracts. Connellsville steam coal is off somewhat, frequently going at as low as \$2.75, byproduct holding firm at \$3.75@\$4.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

Financial. Construction and Manufacturers' News

Construction and Operation

Alabama

RIVER FALLS—The Andalusia Brick Co has plans under way for extensions and improvements in its plant, including the installation of considerable additional equipment. O. L. Benson, Andalusia, and Harold Stanley, River Falls, head the company.

Arkansas

LITTLE ROCK—The Arkansas Brick & Tile Co has inquiries out for power equipment and other operating machinery for installation at its plant.

California

TOBY (Kern County)—The Fremont Salt Co, is planning for extensions and improvements in its plant at Toby, near Mojave, estimated to cost about $50,000, including equipment. J. C. Martin is general manager.

SAN DIEGO—The Savage Tire Co, manufacturer of automobile tires, will install additional equipment at its plant for considerable increase in production.

LOS ANGELES—The Soda & Potash Corp. recently organized with a capital of 3,00,000 shares of stock, no par value, is perfecting plans for the construction of a new plant on local site secured some time ago. The works will include an experimental laboratory for developing new processes of manufacture, and are estimated to cost in excess of $1,500,000, including machinery. The company is also arranging for the operation of raw material lands in Nevada, where extensive deposits of sodium sulphate, carbonate and bicarbonate are available. C. W. Culpepper is president. Edward F. Shaw, treasurer, and F. J. McGuire, secretary.

SANTA BARBARA—The Shell Co of California, San Francisco, has acquired property at Salsipuedes Ave, near Milpas St, as a site for the construction of a new storage and distributing plant, estimated to cost in excess of $500,000, with equipment. Work will be placed under way at an early date. Headquarters are at 343 Sansome St, San Francisco.

SAN FRANCISCO—The Western Sugar Refinery, 2 Pine St, will commence the immediate erection of a new 1-story building at its plant, covering two city blocks on 23d and Delaware Sts., estimated to cost about $245,000. The company is a subsidiary of the Spreckels Sugar Co same address.

OAKLAND—The Richmond Sanitary Mfg Co., manufacturer of sanitary ware, has awarded a contract to Sommerstrom Brothers, 306 11th St, Oakland, for the erection of a new 2-story building at 9th and Alice Sts., estimated to cost about $25,000. L. L. Ford, 306 14th St, is architect.

TEHACHAPI—The Henry Cowell Lime & Cement Co., 2 Market St, San Francisco, is said to be perfecting plans for the early erection of its proposed new cement-manufacturing plant on property recently acquired at Tehachapi, near Bakersfield, estimated to cost more than $1,000,000 with machinery.

RICHMOND—The Synthetic Iron Coloring Products Co., 17th and Chanslor Sts, is planning for the rebuilding of the portion of its drying department recently destroyed by fire.

PITTSBURG—The Columbia Steel Corp, recently organized with a capital of $20,000,000, to take over and merge the Columbia Steel So., with local mills, and the Utah Coal & Coke Co., Salt Lake City, has plans under way for extensions and improvements in the Pittsburg works, to include the erection of a number of new mills and open-hearth furnaces. Tho work will cost in excess of $500,000. Wigginton E. Creed, head of the Pacific Gas & Electric Corp., 445 Sutter St., San Francisco, is president of the new corporation.

Florida

TAMPA—The Citrus Growers Supply Co, recently formed with a capital of $25,000, has plans under consideration for the establishment of a new plant for the manufacture of insecticides for use on citrus trees. E. M. Starnes is president, and R. B. Campbell, vice president.

Georgia

AUGUSTA—Merry Brothers, operating a local brick-manufacturing plant at the foot of Gwinnett St, will install additional equipment for the manufacture of hollow tile. A new kiln, about 800 ft long, is being constructed. The company is headed by A. H. and E. B. Merry.

Illinois

CHICAGO—G. K. Nikolas & Co, 1227 West Van Buren St, manufacturers of lacquers and kindred products, will soon award a general contract for the erection of their proposed new 3-story plant, 50x70 ft, adjoining the present works, to cost approximately $50,000. Meyer & Cook, 30 North Dearborn St, Chicago, are architects.

TAYLORVILLE—The Hopper Paper Co has acquired the local plant of the E Z Opener Bag Co, and will use the structure in connection with its proposed new paper mill for which plans are being completed. The new mill to be constructed will be located on an adjoining site and is estimated to cost $75,000, with the present building, it will provide for an initial capacity of about 20 tons per day. B. Hopper is president, and K. R. Cobine, secretary, treasurer and general manager; Walter H. Provine, Taylorville, is vice president in charge.

Indiana

EAST CHICAGO—The Pressed Steel Mfg Co, of East Chicago, Ind, announces that it will begin construction on its 2-story factory and office structure this year, the building to be used for the production of the Murphy steel car ends. According to plans the company proposes to build a brick, steel and concrete structure to cost $700,000.

INDIANAPOLIS—The Marion Paint Co, 358 South Meridian St, has leased a building at 366 Meridian St, for extensions in its plant. Additional equipment will be installed for considerable increased production.

NEW ALBANY—The Gohmann Brothers & Taylor Co, Silver St, is planning for the erection of a 2-story and basement foundry, 30x220 ft, at its stove and range works, estimated to cost approximately $35,000. Bids will be asked at an early date. Arthur R. Smith, Norton Bldg, Louisville, Ky, is architect in charge.

PENDLETON—The Reformatory Board, Indianapolis, has tentative plans under consideration for the construction of a foundry at the new Indiana Reformatory, Pendleton. J. W. Nash, Indianapolis, John O'Neil and Joseph E. Henning comprise the committee in charge of purchases. G. A. H. Shideler is superintendent at the institution.

INDIANAPOLIS—The Radio Chemical Co, recently organized, has arranged for the establishment of a new plant at 315 North Delaware St.

Louisiana

FOWLER—The Southern Carbon Co, Monroe, La., has plans under way for the construction of a new plant at Fowler, comprising 8 operating units for the prodnction of carbon black and kindred specialties, estimated to cost approximately $800,000, with machinery. The company is also arranging for the erection of a new 2-unit plant at Spyker, and has commenced work on a 6-unit factory at Swartz. The entire project is expected to cost close to $1,500,000, including machinery.

Maryland

BALTIMORE—The Tin Decorating Co., Boston and Linwood Aves., has awarded a contract to the West Construction Co., American Bldg., for the erection of a new 1-story plant, 106x168 ft., estimated to cost about $45,000. Work will be placed under way at once.

Massachusetts

INDIAN ORCHARD—The Fiberloid Corp., manufacturer of celluloid composition products, has tentative plans under consideration for the rebuilding of the portion of its plant destroyed by fire, Jan. 8, with loss estimated at close to $50,000, including equipment.

MANISTEE—The Fuler Fibre Co., Fller City, is pushing construction on its new local plant and plans to have the structure ready for the machinery installation at an early date. The initial works will give employment to about 100 men. M. Oberdorfer is vice-president.

LUDDINGTON—The Stearns & Culver Salt Co has work under way on enlargements and improvements in its plant to develop a capacity of about 600 000 bbl. of salt per year.

Nebraska

OMAHA—The Board of Trustees, Creighton University, has tentative plans in progress for the erection of a 4-story and basement chemistry building at the institution, estimated to cost approximately $300,000. John Latenser & Sons, 732 Peters Trust Bldg, are architects. John F. McCormick is president of the institution.

OMAHA—The Metropolitan Utilities District will build by day labor a new 2-story and basement filtration plant at 28th and Fillmore Sts, 130x240 ft, estimated to cost about $600,000, with equipment. F. D. Wead is chairman of the board.

New Jersey

NEWARK—The Utility Color & Chemical Co, 379-95 Frelinghuysen Ave, manufacturer of varnishes, colors, etc, is planning for the immediate rebuilding of the portion of its plant destroyed by fire, Jan 9, with loss estimated at $35,000, including machinery and stock. Mortimer Davis is president.

NEWARK—The Eberhard Faber Rubber Co, New St, will commence the immediate erection of an addition to its plant at 60 Hoyt St, to cost about $25,000.

LAMBERTVILLE—The Perseverance Paper Mills, Inc, is perfecting arrangements for the rebuilding of the portion of its plant recently destroyed by fire. The company specializes in the production of newsprint under a new process. Henry Weeks is general manager.

ELIZABETH—The Durant Motor Co, Newark Ave, has commenced the installation of oven and other equipment, electrically operated, for drying and baking paints and enamels.

PLAUTERVILLE—Plans are being perfected by stockholders of the Smith Rubber & Tire Co, now in charge of William L. Brunyate, 304 Essex Bldg, Newark, trustee in bankruptcy, for a reorganization of the company and settlement of the receivership. Improvements and repairs will be made at the plant, closely following, and operations resumed.

New York

NEW YORK—The Vacuum Oil Co., 61 Broadway, manufacturer of lubricating oils, etc, has purchased property on the East River water front, from 10th to 11th St for a consideration said to be $200,000, to be used as a site for a new storage and distributing plant for domestic and export purposes. The property was formerly a part of the plant of the Quintard Iron Works.

North Carolina

GREENSBORO—The Andrews Container Co., organized with a capital of $150,000, has acquired a local building to be equipped as a plant for the manufacture of solid fiber and corrugated products. O. B. Andrews is president.

Ohio

AKRON—The Benzol Motor Fuel Co has construction under way on a new plant on East Tallmadge Ave, North Akron, for the manufacture of a new fuel for automobile service, composed of motor benzol and gasoline. The works are estimated to cost about $55,000, and will include storage tankage with capacity of approximately 20,000 gal. G. M. Tucker and C. C. Dilley will be in charge.

CINCINNATI—The Cincinnati Galvanizing Co., McMicken and Tafel Sts., will call for bids early in February for the construction of a new 2-story plant at Chickering St. and Spring Grove Ave., totaling about 15,000 sq.ft., estimated to cost approximately $150,000, including equipment. Carl

J. Kiefer, Room 810, Fourth National Bank, is architect and engineer. Christian Schott is president.

NILES—The Mahoning Valley Steel Co is planning for immediate extensions and improvements in its plant, to include the remodeling of furnaces, installation of bar-shearing and other apparatus. The capacity will be considerably increased

AKRON—The Goodyear Tire & Rubber Co is planning for the immediate rebuilding of the portion of its chemical works, destroyed by fire, Jan. 3, with loss reported at $12,000

Oklahoma

HENRYETTA The Henryetta Glass Co, recently acquired by new interests, has plans under way for extensions and improvements, including the installation of additional equipment for increased production F. A. Patterson heads the new organization

ARDMORE—The Chickasaw Refining Corp, recently organized with a capital of $2,500,000, is perfecting plans for the operation of the local Chickasaw refinery Extensions and improvements will be made in the plant. J. A. Cotner heads the company.

TULSA—The Sinclair Crude Producing Co, an interest of the Sinclair Consolidated Oil Corp, 45 Nassau St, New York, has plans nearing completion for extensions and improvements in its plant and system in the Salt Creek fields The work will include a new pipe line, over 700 miles long, with pumping plants and auxiliary equipment The expansion will cost approximately $500,000

PAULS VALLEY—A bond issue of $188,000 has been approved for a waterworks system, to include a complete purification plant V. V. Long & Co, Colcord Bldg, Oklahoma City, are engineers.

Pennsylvania

PHILADELPHIA The American Bag & Paper Co, 2nd and Vine Sts, has taken bids on a general contract and will soon commence the erection of a new 7-story paper mill, 95x275 ft, at South Bainbridge, Water and Swanson Sts. Clarence E Wunder, 1115 Locust St, is architect

PHILADELPHIA—The Pennsylvania Brick & Tile Co has filed plans for the erection of a new building at its proposed plant at Wensley St and the Delaware River, for the manufacture of cement brick and kindred products The ultimate plant is being designed for an output of 150,000 bricks per day The company has recently been organized under state laws, with H. P. Marr, Kennett Sq, Pa, as treasurer

CONSHOHOCKEN—The Ruth Glass Co is arranging for the early installation of additional machinery for increased production A day and night working schedule will soon be adopted The company specializes in the manufacture of hollow ware

South Carolina

COLUMBIA—The Columbia Electro Plating Works, Inc, is planning for the rebuilding of the portion of its plant recently destroyed by fire The estimated loss has not been announced

Tennessee

UNION CITY—T. C. Fennell and R. E. Wilkins, both of Humboldt, Tenn, are planning for the organization of a company to establish and operate a tanning plant on property acquired at Union City

Texas

DALLAS—The Oak Cliff Paper Mills, Inc, Oak Cliff, near Dallas, has plans nearing completion for additions and improvements in its plant for considerable increase in capacity A new structure to be erected will be used primarily for the manufacture of fiber board, corrugated board and kindred products The expansion is estimated to cost $150,000 E. T. Fleming is president

CISCO—The Eastland-Pioneer Oil Refining Co, recently organized, has taken over the former local refining plant of the Liberty Refining Co, idle for some time past, and will make extensions and improvements to increase the capacity to about 6,000 bbl per day The present refinery will be thoroughly modernized It is purposed to rush the work and have the plant ready for operation at an early date. R. E. Whitlock is general manager.

Virginia

HOPEWELL—In connection with extensions in its local pulp mill, the Stamscott Co., Inc., will make enlargements in its chemical department, devoted to the manufacture of specialties for the production of celluloid, lacquers and other products.

NEWPORT NEWS—Gateways, Inc., 128 24th St., recently organized, has acquired the local plant of the Duristo Paint Co., and will operate the property in the future. Extensions and improvements are planned M. K. Armstrong is president of the new company, and E. D. Pettengill, treasurer

Washington

PROSSER—The Prosser Evaporating Co. is considering plans for the rebuilding of the portion of its plant, destroyed by fire, Jan 2, with loss estimated at about $15,000.

West Virginia

PARKERSBURG The Blackwood Electric Steel Corp has broken ground for the construction of the initial units of its new local plant, consisting of a number of 1-story buildings, with main structure, 140x230 ft The plant will be equipped for the manufacture of electric steel castings. Mills, Rhines, Bellman & Nordoff Ohio Bldg, Toledo, O, are architects and engineers F. S. Blackwood heads the company

Industrial Developments

GLASS—The American Window Glass Co has resumed operations at its plant at Hartford City Ind, following a curtailment for a number of days due to equipment breakage

Hand blowing glass plants in the vicinity of Clayton, N. J., are running at full capacity, giving employment to the largest number of workers in about 10 years past

Window glass plants in Western Pennsylvania are operating at maximum output, with shipments of material during the past few weeks breaking all previous records Working forces at a number of the factories are being increased

CEMENT—The Coplay Portland Cement Co, Coplay, Pa, has resumed production at its local mill, following a shut down during the holidays for repair work

The Phoenix Portland Cement Co, North Birmingham, Ala, is perfecting plans for the early completion of its new local mill which has been in course of construction for a number of months past It is purposed to have the first units in full production early in May The mill will have a rated ouput of 1,500,000 bbl per year

The Lehigh Portland Cement Co has closed its Mill F at Coplay, Pa, for necessary repairs to equipment, and plans to resume as soon as the work has been completed with production on a full capacity basis At a later date, Mill D will be closed for a similar purpose

The Alpha Portland Cement Co. is maintaining production at a normal basis at its mill at Alpha, N. J. The Edison Portland Cement Co is also running full at its plant at New Village, N. J.

LEATHER Tolman, Dow & Co Inc, operating a tannery at Woburn, Mass, is running at close to normal, producing about 1,200 sides of buck and patent leather per day.

England, Walton & Co., Philadelphia, Pa, said to be the largest tanners in the world of oak belting butts, have advanced production about 30 per cent during the past 5 to 6 weeks Increased working forces are being employed at the different tanneries

The Murray Leather Co. Woburn, Mass, is operating a regular capacity, devoting production to patent sides as well as buck skin A normal working quota is being employed

PAPER—Paper mills in the vicinity of Three Rivers, Que, are practically all working at full capacity, with largest available working forces.

The Price Brothers Co, Quebec, is arranging for immediate increase in production at its paper mills in the vicinity of Ottawa, Ont., to include the installation of additional equipment. It is purposed to develop a capacity of 200 tons a day before the close of the year.

The Wayagamack Co, Three Rivers, Que., has advanced production at its local paper mills, and is now giving employment to about 500 men.

The Bathurst Co., Bathurst, N. B., is pushing construction on a new local mill to be used for the manufacture of newsprint, and purposes to have the first unit in service at the earliest possible date. The plant will have a rated capacity of 15,000 tons per annum.

IRON AND STEEL—The Blandon Rolling Mill, Reading, Pa., is planning for the immediate resumption of operations at its local mill, following an idle period of about 24 months. Employment will be given to 125 workers.

The Colorado Fuel & Iron Co., Denver, Colo., has blown in two additional blast furnaces at its plant at Pueblo, Colo., giving employment to a large increased working force.

The American Steel & Wire Co., Anderson, Ind, has placed its local mills on a double turn, giving employment to approximately 600 men

The La Belle Iron Works, Steubenville, O., has blown in its No. 2 furnace, following a shut down for a number of months. A total of 8 sheet mills have also been placed in service after an idle period of about 2 months. The units will be operated at capacity.

The Carnegie Steel Co is making ready for operation at its Bellaire, O., plant and has issued orders for necessary repairs and improvements The company is running full at its Edgar Thomson Works in the Pittsburgh, Pa., district, as well as at its other mills in this section

The Shenango Furnace Co, Sharon, Pa., has completed the remodeling of its No. 3 furnace, and the stack is again in blast. The capacity has been increased from 350 to 500 tons per day.

The Republic Iron & Steel Co., Youngstown, O, is maintaining full operations at its eight furnaces in the Mahoning Valley section, and will continue on this basis for some time to come The company is dismantling its plant in the vicinity of Sharpsville, Pa, and will remove the equipment to another location

The Newton Steel Co, Newton Falls, O., is arranging for the immediate operation of three of its eight new sheet mills, recently completed The five other mills will commence rolling within the next 60 days.

The United States Steel Corporation is operating at 100 per cent at its bar mills in the Youngstown, O, district

METALS—The National Lead Co, New York is operating at full capacity at its different plants under a day and night schedule, giving employment to a large working force

The Susquehanna Casting Co., Wrightsville, Pa has advanced the wages of employees 5 per cent, effective at once. The Riverside Casting Co., with plant at the same place, has made a similar advance.

The Utah Copper Co., Salt Lake City, Utah, is operating at full capacity at its plants at Magna and Bingham The company is said to be producing more metal at the present time than at any other period during the past 4 years

MISCELLANEOUS The Prince Metallic Paint Co, Bowmanstown, Pa, is increasing production at its local plant, and has adopted a day and night working shift, giving employment to more workers.

The Shore Fertilizer Mfg. Co, Plant City, Fla., is completing the construction of a new local plant and plans to place the mill in service before the close of the month.

The Federal Sugar Refining Co., New York, is arranging for the immediate resumption of operations at its mill at Yonkers, N. Y, which has been idle for about 8 weeks past The refinery will give employment to approximately 1,200 men.

A total of 104 sugar mills in Cuba are now in operation, as compared with 54 mills at this same time a year ago.

The Boston Hose & Rubber Co., Boston, Mass., is advancing production at its plant. During the last quarter of 1922 the output averaged 25 per cent more than at any other 3 months' period in the history of the company

Sanitary ware plants at Trenton, N. J., are increasing production, and adding to their working forces

Capital Increases, Etc.

THE RUMFORD CHEMICAL WORKS, INC., Providence, R. I., has filed notice of increase in capital from $1,250,000 to $2,000,000.

THE BEAVER FALLS ART TILE CO., Beaver Falls, Pa., has arranged for an increase in capital from $80,000 to $200,000.

THE JONATHAN BARTLEY CRUCIBLE CO., Oxford St., Trenton, N. J., has filed notice of increase in capital from $125,000 to $500,000.

THE HART GLASS MFG. CO., Dunkirk, Ind., has increased its capital from $300,000 to $500,000 for general expansion.

THE AMERICAN PRINTING INK CO., 2324 West Kinzie St., Chicago, Ill., has arranged for an increase in capital from $100,000 to $350,000.

New Publications

BOOKS

FOOD PRODUCTS FROM AFAR. By *E. H. S. Bailey* and *H. S. Bailey*. 285 pages, over 50 illustrations. Price $3. Published by the Century Co, New York City.

Although written by chemists, this book is offered as a popular treatise of general interest on the subject of how and where our country gets its food. It is a work of popular interest that may be somewhat enhanced to chemists in view of the fact that the senior author is professor of chemistry in the University of Kansas, while the junior author, his son, is chief chemist for the Southern Cotton Oil Co.

PAMPHLETS, ETC.

A FEW SUGGESTIONS TO MCGRAW-HILL AUTHORS is the title of a 20-page pamphlet recently issued by the McGraw-Hill Book Co., Inc., 307 Seventh Ave., New York It is designed to give prospective authors information that will enable them to prepare better manuscripts and save both themselves and the publishers time and unnecessary expense.

DENTAL FILLING ALLOYS is the title of a treatise by N. K. Garhart, of the Garhart Dental Specialty Co., Boston, Mass.

THE ENGINEERING EXPERIMENT STATION of Purdue University, Lafayette, Ind., has issued a bulletin, No. 9, on "The Production of Nitric Oxides and Ozone," by K. B. McCochron and R. H. George Copies may be obtained by writing to the director, Dean Potter.

THE SECRETARY OF COMMERCE, Washington, D. C., has issued his tenth annual report, for 1922.

THE FEDERAL BOARD FOR VOCATIONAL EDUCATION, Washington, D. C., has issued its sixth annual report to Congress, for 1922.

THE IMPERIAL INSTITUTE, London, England, has issued a booklet on "Molybdenum Ores," by R H. Rastall. Price 5s., net.

THE U. S. DEPARTMENT OF AGRICULTURE, Washington, D. C, has issued Parts I and II, "List of Workers in Subjects Pertaining to Agriculture"; Bull. 1108, on "Tables for the Microscopic Identification of Inorganic Salts," by William H Fry, Bull 1122, on "Absorption by Colloidal and Non-colloidal Soil Constituents," by M. S. Anderson, W H. Fry, P. L Gile, H E Middleton and W. O Robinson, Circular 233, on "Motion Pictures of the U. S Department of Agriculture."

THE UNIVERSITY OF ILLINOIS has issued Bull. 131, on "A Study of Air Steam Mixtures," by Leroy A Wilson with Charles Russ Richards; Bull. 132, on "A Study of Coal Mine Haulage in Illinois." by H H Stock, J. R. Fleming and A J Hoskin, Bull. 133, "A Study of Explosions of Gaseous Mixtures," by A. P. Kratz and C Z Rosecrans.

THE IMPERIAL MINERAL RESOURCES BUREAU, London, England, has issued booklets on "Nickel," "Iron Ore" and "Coal, Coke and Byproducts," priced at 1s 6d, 6s and 7s, respectively.

NEW BUREAU OF MINES PUBLICATIONS Twelfth Annual Report by the Director of the Bureau of Mines to the Secretary of the Interior for the Fiscal Year Ended June 30, 1922; Bull. 167, Coal-Dust Explosion Tests in the Experimental Mine 1913 to 1918, inclusive, by George S. Rice, L M Jones, W. L. Egy and H. P. Greenwald; Bull. 188, Lessons From the Granite Mountain Shaft Fire, Butte, by Daniel Harrington; Bull. 209, Fusibility of Ash From Coals of the United States, by W A. Selvig and A. C. Fieldner; Tech. Paper 265 Mesothorium, by Herman Schlundt; Tech Paper 303, Value of Coke, Anthracite and Bituminous Coal for Generating Steam in a Low-Pressure Cast-Iron Boiler, by John Blizard, James Neil and F. C. Houghten, Tech. Paper 306, Operation and Maintenance of Electrical Equipment Approved for Permissibility by the Bureau of Mines, by L. C. Ilsley; Tech. Paper 308, Analysis of Kentucky Coals; Tech. Paper 318, Coke-Oven Accidents in the United States During the Calendar Year 1921, by William W. Adams; Reports of Investigations Serial No. 2416, Properties of Typical Crude Oils From the Producing Fields of Southern Louisiana and Southern Texas, by N. A. C. Smith, A. D. Bauer and N. F. LeJeune; Serial 2406, on Titanium, by R. J. Anderson; Serial 2410, on Contraction and Shrinkage of Non-Ferrous Alloys as Related to Casting Practice, by Robert J. Anderson.

THE COLONIAL SUPPLY Co., Pittsburgh, Pa., is issuing the "Colonial Soldier Almanac for 1923."

New Companies

THE CHAREX CHEMICAL Co., Rochester, N. Y., care of Charles E. Bostwick, Insurance Bldg, Rochester, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are H. C. and H M Williamson.

THE STEARNS & CULVER SALT Co, Ludington, Mich, has been incorporated with a capital of $300,000, to manufacture chemical salts and kindred products. The incorporators are E. E. Barthell, W. T Culver and W A. Spencer, Ludington. The last noted represents the company.

THE CAPITOL BLOCK & BRICK Co., Trenton, N. J., has been incorporated with a capital of $50,000, to manufacture brick, tile, blocks and other burned clay products. The incorporators are Peter J and Paul N. Jachetti, 436 Bert Ave, Trenton. The last noted represents the company.

THE HERCULES OIL Co, 4650 Iowa St., Chicago, Ill, has been incorporated with a capital of $10,000, to manufacture lubricating oils and affiliated products. The incorporators are Henry J Brandt, Lawrence A. Cohen and A. L. Rittenberg.

THE J. B. NEWTON TURPENTINE Co., Hillsdale, Miss., has been incorporated with a capital of $100,000, to manufacture turpentine and kindred products The incorporators are J. B., R. M. and J R. Newton, all of Hillsdale.

CRANE & Co, INC., Dalton, Mass., has been incorporated with a capital of $3,000,000, to manufacture paper products, succeeding the company of the same name with local mills. Reuben C. Pierce is president, and Payson E. Little, treasurer.

THE FRANKS CHEMICAL Co, Brooklyn, N. Y, has been incorporated with a capital of $30,000, to manufacture chemicals, soaps, etc. The incorporators are J. M. Franks, P. M Lah and A. M. Rosenthal The company is represented by Davis, Siegel & Nathan, Broadway and 34th St., New York, N Y.

THE CHICAGO JAPANNERS, INC, 1160 West 22nd St., Chicago, Ill., has been incorporated with a capital of $150,000, to manufacture paints, oils, varnishes, etc. The incorporators are Thomas P. McVicker and William J. and G. A Miskella.

THE STATE LINE CHEMICAL CORP, Bristol, Va, has been incorporated with a capital of $30,000, to manufacture chemicals and chemical byproducts. The incorporators are G C Cole, M. T Repass, and Joseph A Caldwell, all of Bristol

THE DUTCHESS COUNTY CHEMICAL Co., Jersey City, N. J., care of the Capital Trust Co of Delaware, Dover, Del, representative, has been incorporated under Delaware laws, with capital of $600,000, to manufacture washing powders, cleansers, and other chemical compounds The incorporators are H C Schuckhaus, Jersey City, M A Kern, New York, and A. H. Wylie, Washington, D C.

THE LUCAS BRICK Co., Portland, Ore, has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. Moses M. Lucas is president and treasurer and Brighton E Lucas, clerk and representative, both of Portland.

THE HENNETT METAL TREATING Co, West Hartford, Conn., has been incorporated with a capital of $50,000, to operate a metal-treating plant. The incorporators are H. R. Barker, A J. German and A L. Davis, all of Waterbury, Conn.

THE KISKI LIME PRODUCTS Co., care of the Corporation Trust Co. of America, du Pont Building, Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $50,000, to manufacture lime and kindred products.

THE CENTRAL OIL Co., El Dorado, Ark., has been incorporated with a capital of $1,000,000, to manufacture petroleum products. The incorporators are Patrick Marr, W S Eakens and R. G. Ferrell, all of El Dorado

THE DE LONG-KENDRICK Co, Newark, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture metal alloys. The incorporators are Louis DeLong, Richard B. Downing and Kenneth A. Depew, 345 Halsey St., Newark. The last noted represents the company.

J. B. CHAPPELL, INC., Philadelphia, Pa., has been incorporated with a capital of $10,000, to manufacture paints, varnishes, etc. Walter Beahart, Roxborough, Philadelphia, is treasurer, and represents the company.

THE HOFFMAN BROTHERS TANNING Co., 4701 Grand Ave., Chicago, Ill., has been incorporated with a capital of $250,000, to manufacture leather products. The incorporators are Olaf C. and Anton R. Hoffman, and Carl Peterson.

THE NATIONAL SPEEDWAY REFINING Co., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under state laws with a capital of $150,000, to manufacture refined oil products.

THE FIELD PRODUCTS CORP., New York, N. Y., care of M. Brandt, attorney, 276 Fifth Ave., New York, representative, has been incorporated with a capital of $30 000, to manufacture chemicals and chemical byproducts. The incorporators are W., D. and H. J. Greenfield.

THE WULBERN FERTILIZER Co., Charleston, S. C., has been incorporated with a capital of $150,000, to manufacture commercial fertilizer products. E. N. Wulbern is president and treasurer; and William E. Jones, secretary, both of Charleston.

THE LIBERTY MIRROR WORKS, INC., Pittsburgh, Pa., has been incorporated with a capital of $150,000, to manufacture mirrors, glass products, etc. William H. Colbert, 6615 Kelly St., Pittsburgh, is treasurer and representative.

THE SMACKOVER VALLEY OIL Co., Camden, Ark., has been incorporated with a capital of $250,000, to manufacture petroleum products. A. M. Sutton is president and general manager; and W. M. Worthen, secretary, both of Camden.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9.

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb 19, 1923

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb 8 and 9, 1923.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

CANADIAN PULP AND PAPER ASSOCIATION will meet at the Ritz-Carlton Hotel, Montreal, Jan 25 and 26.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

The Law And the Profits

IN ENGLAND last year, in a hearing before the Board of Trade, the question was argued before a referee whether or not calcium carbide might be included among the substances covered by the safeguarding of industries act. The referee was learned in the law, but was in no sense a chemist, so the argument became long and very much tangled up. He did not have even the aid of a chemist to shed light on the subject, consequently the hearing became a curious discussion in chemistry by lawyers. His conclusion was that calcium carbide is not a synthetic organic chemical, and is therefore not properly included under the act.

Sir WILLIAM J. POPE discusses the subject in *Chemistry and Industry* (vol. 42, No. 1) and declares the proceedings to have been "an orgy of misinterpretation and misapprehension." It was admitted that calcium carbide is a synthetic compound, but the expounder of the law shied at admitting it to be organic. Then Sir WILLIAM brings to bear his proofs that organic chemistry is the chemistry of carbon compounds, and he makes a good case of it. He quotes from KEKULÉ, LAURENT, VAN'T HOFF (who said that "organic chemistry has for its object not only the study of the compounds of carbon, but also that of the element itself"), H. E. ARMSTRONG, BEILSTEIN, and numerous other authorities. Next he takes up those who have endeavored to qualify the statement. Thus SCHORLEMMER called it "the chemistry of hydrocarbons and their derivatives," but Sir WILLIAM points out that while this would exclude carbon monoxide, it includes carbon dioxide as a derivative of methane, but again would exclude purine. FRANKLAND said that organic chemistry is restricted to compounds the molecules of which consist of two or more atoms of carbon, directly combined either with carbon, nitrogen or hydrogen. This excludes, for instance, perchlormethyl ether, $(CCl_3)_2O$, from the category. REMSEN says that, strictly speaking, the carbonates should be included in organic series, but that it is customary to treat these widely distributed substances under the head of inorganic chemistry. G. S. NEWTH in his textbook on inorganic chemistry says, "No exact definition of organic chemistry has ever been framed" and that it is "the chemistry of carbon compounds with certain generally acknowledged exceptions." He is wrong in his opening paragraph: All the carbon compounds is an exact definition, and the exceptions are not generally acknowledged. E. P. MOELLER is his "Law of Atomic Linking" (1895) declares that "in all organic compounds carbon and hydrogen appear as never failing constituents." Of course that is absurd.

The conclusion we reach is that it is better in contracts and in law and in all writing that is likely to pass through the fire of juristochemistry, to say *carbon* rather than *organic* compounds. By juristochemistry we mean those chemical discussions and disputes that are carried on at court without a knowledge or understanding of the science.

Salesmen's Report On the Chemical Exposition

FOR some months past a special committee of the Salesmen's Association of the American Chemical Industry has been investigating the Chemical Exposition with a view to proposing constructive measures for improving the usefulness of that annual affair. The final report of the committee is recorded in our news columns.

From a reasonably intimate familiarity with the Chemical Exposition we have read the report carefully to see what elements of novelty it contains. It is a constructive document and shows a commendable desire on the part of the Salesmen's Association to obtain for the exposition the hearty support of the chemical industry *per se*. It proposes also to insure an appropriate attendance by holding during exposition week a congress of chemical and consuming industries as represented by various technical and trade organizations. It suggests a fund to be created out of a part of the Exposition Company's receipts to be expended on educational exhibits of the chemical industries; and finally it recommends representation for the executives and sales departments of the industry on the advisory committee of the exposition.

It is not in derogation of the salesmen's efforts to say that all of these proposals are not new; but at least they are brought together at one time as the expression of opinion of an important organization. All of them will be susceptible of easy execution with the exception of the proposed congress, which will require the best efforts of the Salesmen's Association to induce a large number and variety of technical and trade associations to forego their customary meetings and join in a common plan for the promotion of the chemical industry. It is not impossible, but it will not be easy to accomplish.

Two points of interest about which considerable controversy has been waged—namely, annual or biennial expositions, co-operative or private shows—have been settled for the moment. The annual show is regarded as essential for the time being, and the co-operative show is dismissed as undesirable if private management will heed the desires of those who make the show possible. It would now seem as though we can look forward without distraction to a satisfactory Chemical Exposition in 1923.

Fuel Supply a Factor In Industrial Development

NATURE has provided one of the most convenient forms of fuel in the natural gas resources of the country. These resources have been developed on a tremendous scale largely for public utility gas supply. During recent years, however, there have been numerous discoveries of natural gas so located that it cannot be utilized economically for city supply. The question has therefore been raised how best to apply this splendid resource to industrial purposes. In the state of Texas there have been a number of such problems confronting property owners and public officials. Referring to one of these cases, a state official said: "It has been our purpose and effort to bring these fields into contact with enterprises which would convert this gas to commercial uses not wasteful. And I believe that the fields present today an inviting opportunity to capital."

The case to which this official made reference is but one of a number where large supplies at points some distance from great municipal centers offer immediate prospect of cheap, adequate fuel supply. No group of industries is better suited to use this resource than the chemical and metallurgical industries. The time is past when resources of this sort are going to be used extensively for the crude operations of brick-making, boiler firing and other heating work that can be done equally well by coal. In general state officials frown upon that type of natural gas utilization; in fact it is forbidden in some states. But many fine industrial heating operations that require close control of temperature can use gas supplies such as these to great advantage; and it is well recognized that the efficient burning of this gas for heating operations of high order can properly be encouraged by the public official.

It will be well if industries having heating problems of this sort will investigate some of the Texas, Wyoming and other Western gas occurrences for which there are no other close-by markets. There should be a basis of mutual service to the local communities and to those industries through their development.

The Outlook for Better Trade Statistics

ONE of the notable accomplishments of the Department of Commerce since it has been under HERBERT HOOVER's direction has been a marked improvement in the character and scope of the governmental statistical services. With the inauguration of the *Survey of Current Business* timely figures on production, stocks and prices were made available to industry. Progress in the case of foreign trade statistics, however, has been somewhat less pronounced, but recently some changes have been made which promise greatly to facilitate the compilation and dissemination of import and export figures. In the first place, new schedules have been worked out which show imported commodities in much greater detail and at the same time so arranged as to give figures which are easily compared with production and export data. Production plus imports minus exports has long been a favorite formula for the statistician who wishes to approximate the total consumption of a commodity.

The revised import schedules went into effect with the enactment of the new tariff, Sept. 22, 1922. New export schedules have been in use for several months and certain improvements have already become evident. Quantity figures are now obtained for many commodities for which only values were previously available. This greatly increases the accuracy of these statistics, for in the past, as has been pointed out by the manager of the foreign commerce department of the Chamber of Commerce of the United States, export declarations have often been carelessly made at purely fictitious values. Thus copper wire had been billed at 4 cents a pound, white lead at 2 cents a pound, and so on. Obviously export values thus obtained are practically worthless in sizing up an export market.

Furthermore our statistical service has been considerably strengthened by the recent action of Congress in authorizing the transfer of all statistical work on imports and exports from the customs service of the Treasury Department to the Bureau of Foreign and Domestic Commerce. With the new schedules in operation, with the government's statistical machinery working more efficiently and with both importer and exporter co-operating to make their declarations as accurate as possible, 1923 should mark a new era in a sort of service that can be made a most effective agent in the promotion of our foreign trade.

Intelligent Use Of Intelligence Tests

THERE are at least two general types of intelligence tests. One is an information test that seeks to ascertain the breadth and accuracy of an individual's knowledge. The other is a test that evaluates his mental agility, quickness of decision and accuracy of judgment. All intelligence tests seem to have played in hard luck. The prominent experimenters were often inexpert and dogmatic and their conclusions have pyramided until we have been given such monstrous statements as "the average adult intelligence in America is that of a 12-year-old boy." WALTER LIPMAN has pointed out how silly this is. The average intelligence must by definition be that of the average adult. Whence then the startling conclusion? A pre-war experimenter had carried out a series of tests on less than a hundred Californians. He assumed that the average rating obtained was equivalent to adult intelligence, or 16 years, and he extrapolated back to the theoretical value which should be obtained by persons of 14 and 12. Then came the remarkable army tests, over 2,000,000 of them. The California experimenter tried to translate these results into the California rating, a procedure both hazardous and questionable, and arrived at the remarkable conclusion mentioned above.

At present the attitude toward intelligence tests oscillates between amusement and ridicule. This is unfortunate, for we are neglecting a most useful tool. A recent folder from the Engineering Foundation tells an interesting story of the use of intelligence tests. It seems that the salesmen in a certain organization were all given an intelligence test and strangely enough the relation between high intelligence and sales return was apparently nil. This was a facer until it was discovered that the salesmen were not well paid and those who stayed with the company long enough to develop good records were stolid men contented with the low pay and slight advancement. This led to the use of the test in such a way as to eliminate as candidates for the job of salesmen, first, those who were of such inferior mentality that they could not reach the lower critical

score, and second, those who obtained a mark above a certain other critical score, since the latter would not long be satisfied with the low pay of the salesman in that organization.

The whole subject is in its infancy, so it is refreshing to hear of intelligent use of intelligence tests. We commend the idea to your attention as being promising of fruitful results in industry.

Promoting a Policy of Interchange of Information

IT IS significant of a nascent era in chemical industry that such studies as those of C. C. VAN NUYS on rectification are fostered and encouraged and then made available for chemical engineers. Within the scientific memories of most of us distillation and rectification were essentially empirical, practically solved problems. Experience told how many trays to use and how large the column should be.

Mr. VAN NUYS has attacked the problem thermodynamically and his analysis of variables and limiting conditions has been more rigid and more complete than any yet published. The results and formulas given in his articles, the first of which appears in this issue, are the basis of production in plants of the Air Reduction Co. They have passed the pragmatic test: they work. Purer products and higher yields at the same time have been an immediate result.

The significant facts are, first, the inception of this theoretical research and its distinct success; and second, the publishing of the theoretical basis upon which the results are built. Such things cannot help but produce an optimistic feeling and strengthen the belief that perhaps chemistry will yet pass through that beneficent revolution which has made American metallurgy the most progressive industry in the world—a revolution that will foster and encourage a free exchange of ideas.

An Outside View of Our Tariff Problems

OCCASIONALLY the chemical industry is accused of inbreeding. The criticism is made that we have isolated ourselves from the general public and have been satisfied to look out on the great economic problems of the nation from the very narrow, if not selfish, viewpoint of our industry or profession. Without debating the justification of such a criticism, we believe it is nevertheless worth while to take note of the prevalence of this view. It is for this reason that we wish to call the industry's attention to a rather unusual article on the tariff by Prof. F. W. TAUSSIG, which appeared in a recent number of the *Quarterly Journal of Economics*. Its author has long been recognized, at least among economists, as an outstanding authority on the tariff, although his well-known views along the lines of free trade and low duties have never won for him a large following among the protectionists. His present article, however, is of the nature of a historical account of the economic and industrial developments leading up to the enactment of the new tariff. Excerpts from it having particular bearing on the chemical industry have been reprinted on page 210 of this issue.

It is our belief that in this discussion of the "purely economic aspects of the case" our readers will find a rather novel line of thought. The comparison of the German and American industrial ways and aptitudes and the conclusions as far as the dye industry is concerned would seem to be fundamentally sound. On the other hand, we can scarcely be expected to add our approval to the author's apparent disposition to subordinate the "war argument"—i.e., the chemical industry's relation to the national defense—in favor of such an idealistic consideration as the economist's theory of the international division of labor. As far as we are concerned, stern realities have already answered "the old question of whether it is worth while to restrict the advantages of the international division of labor because of a possibility of sudden disruption."

The question of rates and the application of the American valuation plan bring up still other controversial issues on which we have already made our stand. Suffice it here to say that the effectiveness of these provisions will turn largely on their administration and that time alone will tell whether or not "the new rates of duty are extremely high" or the American valuation plan is a workable administrative procedure.

Coal and Chemical Engineering

ANNUALLY the American miner takes from the ground a larger tonnage of coal than of any other single mineral product; yet in general the utilization of this material has followed the happy-go-lucky, spendthrift American method of "easy come, easy go." Lately, however, with increasing cost of coal production and with increasing irregularity in coal markets, even the coal-mine operator is beginning to see that there is a real engineering problem in the utilization of our fuel resources. A representative of one of the large coal companies recently expressed himself thus: "We feel that the time has come when a distinct advance should be made in the marketing of our product and look to gasification as a solution of at least part of our problem."

Somewhat the same point was stressed by the official representative of the American Gas Association when he appeared before the Federal Coal Commission. He emphasized the fact that the gas industry is a branch of chemical engineering requiring particular kinds of coal for processes which are not haphazard but based upon the latest and best of science and technology.

These are but two of the recent evidences that coal is recognized as an important raw material for American industry. And gasification of the coal before use as a fuel is a logical step forward in the application of these ideas.

A great deal of research on coal processing has already been done, but we need much more. We need particularly to learn how to get daily the maximum output in millions of heat units per dollar of investment cost. The problems of quality of product and regularity of operation have been largely solved by the makers of water-gas machinery, by coke-oven builders and by the contributions of skilled operating men in all classes of gas works. Yet today we find that one of the principal items in cost of gas, whether for city supply or for industrial use, is that of capital charges. There is still much to be done by the chemical engineer in devising more productive and efficient schemes in order that this part of the problem may not remain as serious a one as it now is.

Readers' Views and Comments

"Chem. & Met." as a Text Book

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have a new use for *Chem. & Met.* which is working out pretty well in practice, and that is as a text book. I have a class in industrial and organic chemistry composed of young fellows who work all day in the industry and then come to school five nights a week. They really do come, too; not only is attendance required, but they are interested. Furthermore, each knows more than I do about some one or two things, and it is my job, in part, to even up their general knowledge of chemistry.

There is no one book I can ask them to get which is within the price limit and not too advanced, so I have arranged for them to each take *Chem. & Met.* and every week we go over it. Sometimes articles are assigned, sometimes we take a chance, and, pretty regularly, the price lists are used as a sort of old-fashioned spelling bee, the fellows telling whence things come, how they are made and what they are used for. They are also expected to be able to answer questions on the advertising pages along the same lines. Of course the regular lectures, coming before and after this session with the paper, may or may not hit something in that particular issue, but very often they do, or at any rate some matter which has recently had some notice in the patent lists.

As the year goes on and we get a larger background there is an increasing number of articles which bear on what I have been telling them, and my hope is to have every student able to tell something about all the common chemicals and to read most of the articles with intelligent interest by the time we have finished our course. It seems to be working out that way; at any rate they are coming to see the length, breadth and depth of the knowledge of chemistry, and how each of them fits in.

Steel at Moderate Temperature

To the Editor of Chemical & Metallurgical Engineering

SIR:—Several articles have recently been published in reference to physical tests on iron and steel at elevated temperatures. An article on "The Blue Brittleness and Aging of Iron" by Dr. Fettweis was published in *Stahl und Eisen* for Jan. 2 and Jan. 9, 1919, which I think is a most valuable contribution to the literature. Dr. Zay Jeffries is the only writer in this country who has made any reference to the work of Dr. Fettweis; at least no other reference has come to my notice. This leads me to believe that this important work has been very largely overlooked.

At the head of the article by Priester and Harder on "Effect of Temperature on the Mechanical and Microscopic Properties of Steel" (*Chem. & Met.*, Jan. 17, 1923, p. 111) this editorial summary appears: "Properties of a low-carbon steel in the blue heat range are inherent to that temperature and are not duplicated when same metal is tested at room temperature after a corresponding tempering." I do not believe this statement holds true. I believe the results can be duplicated when tested at room temperature *provided the metal is cold-worked before or during the tempering.* Fettweis demonstrates this clearly.

That Priester and Harder did not get a higher value at 300 deg. than at room temperature (Fig. 3, p. 12) seems to be due to the "annealing" effect at this temperature overbalancing the "aging" effect, as they started with quenched samples.

At the September, 1922, meeting of the Electrochemical Society a paper was presented by Norman B. Pilling on "Effect of Heat-Treatment on the Hardness and Microstructure of Electrolytically Deposited Iron," and the increase in hardness at 300 deg. C. was ascribed to the decomposition of the iron-hydrogen compound. That the iron is deposited in a strained condition has been clearly demonstrated and I believe the increase in tensile strength at the blue brittle range is to be accounted for in the same way as that noted in iron strained by cold-working and then heated to the blue brittle range.

Numbering Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—The editorial pages of *Chem. & Met.* have been the source of so much instruction to me, and I have come to hold them in such high esteem, that I cannot forbear a few words of mild protest regarding the discourse on "Numbering Steels" appearing in your issue of Dec. 27. Having taken an interest in that subject for some time, I read your editorial with considerable eagerness, hoping for the usual clarifying exposition of a difficult topic. Forgive me, therefore, if I confess to a keen disappointment and a feeling that the matter was wound into an unintelligible tangle and dropped there.

You proceed to show that the SAE system, at first logical, has now become arbitrary, because of the constantly increasing complexity of steels offered, but you cite this arbitrary class numbering as an *advantage,* although arbitrary numbering was the very evil which the SAE system was originally designed to avoid! You next lament, Friend Editor, that "a logical code indicating the chemical composition of steels has so far eluded discovery" and observe how much more difficult it would be to devise a code which, in addition, will denote "that physical property" which is desired. Again, you assure us that information on the chemical composition is only incidental, since an ordnance constructor wants not chemical analysis, but a gun tube, with high transverse strength and ductility; and so on. We are then asked how all this is to be got into one code.

The answer, of course, is: It is not. Even if all the properties named were to be got into a code, somebody would come along with a lot more real or fancied properties that could not be coded. Moreover, if none of these gentlemen care about composition, as you intimate, why are modern steel specifications tending more and more to include chemical analysis?

The point of the whole discourse is finally disclosed to be that the only known way to describe a steel is in a detailed specification, and that it does not really matter in the least how the specification is designated. It is added that all of the steels might (for "practical" purposes?) be indistinguishable chemically, good steel being "more than low phosphorus and sulphur."

All of which leaves us just where we started, although a trifle dizzy.

Have the editors of *Chem. & Met.*—so often leaders of progressive thought in affairs technical—really nothing better to offer than persiflage on a subject which has called together a group of engineers, representing perhaps thirty national organizations on a series of conferences? Can you not give your readers some really constructive, helpful, logical and practical suggestions on this important and delicate subject?

Perhaps this code problem seems complex and difficult because we make it so. It is only when we try to "discover" a code system which will express in one neat and compact little symbol all we want to know about a steel, including diverse and sundry physical properties, method of manufacture, its physical state, heat-treatment, and even the purposes for which intended, with or without chemical analysis (all of which have at various times been suggested), that we get into a muddle and reject the idea as impracticable. Of course it is impracticable to expect one symbol to do all that work, for it would then be no longer a symbol, but merely a specification number, and we should have to refer to the specification to get our data.

However, what is really under consideration is "a numbering system for *steels*—not the *properties* of steels. That there is a real need for such a system has already been definitely agreed upon.

When the SAE founded its system, a dozen years ago, it made its symbols express the principal alloying components, carbon, nickel, chromium, etc., and did not try to make the same symbol tell all the physical characteristics which any steel might, under various treatments and circumstances, possess. It recognized the fact that one steel may be made to meet a wide variety of physical specifications by different treatments, and also that a given set of physical properties can be met by a considerable number of different steels appropriately treated. It stuck to chemical analysis for its symbols, and took care of the other properties by means of specifications. The system has been quite successful and very useful. Unfortunately, the SAE code, using numerals only, is not capable of unlimited expansion, and cannot be logically extended to take care of all the useful alloys which are developing. This is admitted. What is needed, therefore, is a truly elastic and comprehensive symbol system for steels, showing the principal components, which can take care of any useful steel now existing or which may exist in the future. Such a code cannot be "discovered," but can and will be developed by logical thought.

The answer seems to be found in an abbreviated chemical formula—that is, a code wherein the important elements are represented by letters corresponding to or suggesting their chemical symbol and the approximate quantities of these important elements are indicated by numerals. Here we have letters and numbers each acting in their true function—letters for names and numerals for amounts. The principles of such a code have already been outlined and shown to be quite practicable. (Universal Steel Code, Knerr & Collins, *Iron Age*, Sept. 1, 1921.) A code along very similar lines (although with some objectionable details) has recently been tentatively issued in Europe by the Standards Committee of the Swiss Association of Engine Builders.

Once having a truly elastic, comprehensive, brief, logical and easily learned and remembered symbol system for *steels*, we can proceed to indicate the physical characteristics desired in any given steel by a specification number, or by an appended symbol, if we so desire. Special chemical characteristics, such as high or low phosphorus and sulphur, etc., may also be indicated, where necessary, without confusion.

Naval Aircraft Factory, Philadelphia, Pa. HORACE C. KNERR.

Importance of Proper Technical Testimony in Patent Suits

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Jan. 17 under the head of "Patent Notes" there are two pages devoted to a review of the decision of the N. Y. courts in the infringement suit of the Philadelphia Rubber Works Co. vs. the United States Rubber Reclaiming Co. claiming infringement of the Marks patent on the "alkali process" of rubber reclaiming.

It may not be generally known that the Ohio court's decision on the validity of these patents was quite at variance with the New York court's decisions.

The Philadelphia Rubber Co. sued the Portage Rubber Co. of Akron for infringement of the same patents and at about the same time. By expert testimony it was shown that a number of patents had been issued long before on the use of both alkali and acids with various heating methods for reclaiming rubber and that in the Mitchell patent it was claimed that it had been discovered that there was advantage in submitting rubber with reclaiming agents "either acid or alkaline" to heat under pressures comparable to that specified in the claimed process.

It was further shown by expert examination of the file wrapper and contents that the Patent Office had been misled by erroneous statements and affidavits in the case which claimed that all of the sulphur, both free and combined, was removed, thus producing a new product, while admissions of complainants at the trial proved that no combined sulphur was removed by the treatment of vulcanized rubber with 3 per cent caustic soda at 150 lb. steam pressure for 24 hours, which was the claimed process.

Further, it was shown the court that the object of reclaiming was, first, to remove fiber and that acid best removed cotton fiber; second, that the free sulphur should be removed and that this could be done at ordinary pressure by boiling in weak alkalis, a process commonly used to prevent "blooming," and third, that plasticizing was a function of heat and time and was not affected by the chemicals.

Defendants had modified their process so as to remove the fiber first with acid in open tanks and then this was, after removal of acid, treated with alkali at lower pressure and for shorter time than that specified by the patent and that necessary for devulcanizing by its use.

With these facts brought out by expert testimony, the District Court of Northern Ohio decided that the patent was invalid on account of fraud practiced on the Patent Office in claiming the removal of all the sulphur,

but a rehearing was granted because defendants had not alleged this as defense. On the rehearing the defence offered no chemical testimony and the judge decided from the evidence that, at the time of the patent application, there was no way known to determine whethel combined sulphur was in the reclaimed rubber or not. Of course all chemists will see at once that the judge was misled on chemical facts. But he decided that the patent was invalid anyway on account of the anticipation by the cited Mitchell patent.

On appeal to the Circuit Court of Appeals of Ohio in Cincinnati, official cognizance was taken of the fact that in the meantime the New York courts had held the Marks patent valid and infringed, but the court decided that it was not necessary to decide this point, as it was convinced the technical testimony had made it plain that the defendant, Portage Rubber Co., was using a different process from that claimed by the patent in suit and that therefore there was no infringement.

Thus it is seen that in the original home of the "alkali" process the patent was twice declared invalid, while in another state the courts of equal standing on different testimony declared the patent valid and infringed. This shows the necessity of such technical testimony that the judges can perceive the actual chemical principles and practice involved in any patent brought before them. Usually they are ignorant of the chemistry involved, but understand logic and can comprehend any chemical proposition explained logically and lucidly to them.

Accelerated Reactions in Pulsating Gas Currents

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reference to the article "Accelerated Reactions in Pulsating Gaseous Currents," I have no experience with the suggestion therein contained. I do know, however, that the problem of "channeling" is a very serious one in many catalytic gaseous reactions and anything that may be done to obviate the difficulties which so arise would be of very considerable importance in the technology of such processes. I believe that definite information concerning the advantage or otherwise of such pulsating currents might be very readily attained in the study of a well-chosen catalytic gaseous reaction taking place in contact with a solid contact agent. I think it should be possible to determine definitely what improvement might be effected by the pulsating process. And that, perhaps, more readily than in the case of absorption processes mainly discussed in the article.

HUGH S. TAYLOR.
Princeton University,
Princeton, N. J.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have reread the article on "Accelerated Reactions in Pulsating Gaseous Currents." It seems to me to be a very good article from a standpoint of getting one to consider the possible benefits from pulsating gaseous currents.

However, the question came into my mind two or three times, Does the increased efficiency, due to pulsating gaseous currents, compensate for the increased cost of producing them? Can this article be followed by one giving quantitative figures showing in one or two instances the increased capacity which the authors' claim? For example, they claim increased capacity in absorption towers with pulsating current and that gas producers operate more regularly and with greater output when operating with a pulsating current or blast. Proving these points would be a very valuable thing and some data should be given to support their case.

An Oil Well in a Graveyard

To the Editor of Chemical & Metallurgical Engineering

SIR:—No doubt you will be surprised to observe the California postmark on this communication, so permit me to explain that the insufferable weather of the metropolitan district induced me to leave my office in charge of my son, Marcus, and set out on a jaunt to the Golden Gate. Yesterday, while on a little excursion to Long Beach, I chanced upon a sight so odd, and one which inspired such humility, that I snapped the photograph which you will find inclosed. An oil well in a graveyard! It is producing, too.

A PRODUCING OIL WELL IN A CEMETERY

I am sure you will understand the irresistible urge that came over me to philosophize on the brevity of this fleeting shadow and the cynical humor of the situation. Evidently, one need no longer be a Pharaoh to "make" the front page. And who shall say that the account of the discovery of Pharaoh's tomb, his mummified remains with his favorite pocket flask and a somewhat moldy but otherwise perfectly preserved pâté de fois gras, his favorite dish, may soon be driven to a less prominent position by a column headed, "300 Barrels a Day of Paraffine Base Crude From Grave of John Doe."

I note that you propose an epitaph in an editorial of your issue of Jan. 3, "Here lies John Doe—Engineer." The spirit of your thought is indeed commendable, but fancy the dismay of John's shade, passing by 500 years later and reading, directly under the Requiescat in pace, —"S. O. Co. of N. Y. Keep off!" As a matter of fact, my guide assured me that no evidence has been found to indicate that the oil was derived from decaying hu-

man remains. But I must close, or you will be waiting my demise in order to stake out a "gusher."

A gruesome subject, Mr. Editor. I believe I will run down to Hollywood this afternoon. MARTIN SEYT.

Dirt in Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent issue appeared an editorial on the subject of "dirty steel." There are certain phases of this on which I should like to present another viewpoint. In reading this article there is a tendency in the reader's mind to find a direct condemnation of steel made in large quantities—"tonnage steel" it is termed.

That steel made in smaller quantities may perhaps appear better from a theoretical standpoint or from laboratory examination will not be questioned. There is, however, a decided difference of opinion as to the actual commercial value of such differences as may appear in favor of the smaller lot. When one considers the successful application of "tonnage steel" in tremendous quantity, particularly in the automotive industry, which was directly mentioned, one may hesitate to condemn offhand this material.

It is true that "dirty steel" has been found and that it has caused trouble, but it must be remembered that when such cases have been found they have received exceedingly wide advertising. It is not always remembered that such cases represent an extremely small proportion of the amount in service. Furthermore little mention is made of the large quantities which render excellent service.

In the writer's experience with steel, covering about 15 years, of which 10 was spent in the automotive industry, he has had his share of difficulty with seamy and dirty steel. This, however, represents a very small proportion of the troubles which have occurred in the use of steel and has occurred less and less as practice has improved. Furthermore, the steels made in small quantities with considerable care have by no means lacked representatives which showed this condition.

Much of the condemnation of certain inclusions in steel has arisen from a lack of complete analysis of the factors governing the application of the steel. Many cases of failure which have been stated to be due to inclusions or dirt have been due primarily to faulty design. The effect of a sharp corner or nick is now quite well understood. Tool marks represent a phase of this. When fracture occurs because of tool marks, it is not always a simple matter to demonstrate this, because after it has occurred the mark has disappeared. All steel contains more or less inclusions and if an obscure break occurs it is usually quite a simple matter to find inclusions with which it may be connected. The line of reasoning that the break was not caused by the inclusion but rather followed it along the line of least resistance, being caused by an overload due to the mechanical condition of the steel, requires an intimate knowledge of all the factors which enter in. This example will serve to illustrate the fact that troubles arise frequently for which the condition of the steel is not at all responsible.

The writer is holding no brief for "dirty steel" nor for "tonnage steel" in all cases. There are many cases in which exceeding care is necessary—for example, in tool steel from which costly tools are to be made. This is written to call attention to the fact that "tonnage practice" is not to be condemned in any wholesale way. There may be makers whose practice is such that their steels are marketed in bad condition, but on the other hand it is not at all difficult to select many whose "tonnage steels" are of excellent quality. Competition will do the rest.

The proof of all this does not lie in any laboratory examination of an individual case carried on in a spirit of condemnation tending to locate the causes in the steel. It comes rather from the results of years of use. The greater bulk of forgings, for example, comes from "tonnage steels," yet we are not confronted by any wholesale failures in service. This applies to the automotive industry as well as to industry in general.

There is another factor which seldom enters into a discussion of this situation but which nevertheless has a very direct effect, and that is cost. In dealing with quality in steel there is often a marked tendency to avoid a discussion of this factor, but in spite of this it has a very direct effect in the final analysis.

To illustrate we will assume that the loss due to dirt inclusions in "tonnage steels" is one-tenth of 1 per cent. That this is a high estimate will be generally admitted if all industry is considered. If to eliminate this it becomes necessary to increase the cost of the raw material 50 per cent or perhaps more, it is quite evident that economic pressure will eventually require a simpler solution. If to this is added a doubt that 100 per cent perfection will be gained, there will be lacking the necessary pressure to force a change.

With proper attention to detail in manufacture—for example, in ingot pouring and cropping—there is no reason why "tonnage steels" should not meet "tonnage requirements"; in fact they are doing so. Lack of careful practice in one mill is no reason for wholesale condemnation of all. RALPH H. SHERRY.

Elizabeth, N. J.

Problems in Sodium Sulphide Manufacture

To the Editor of Chemical & Metallurgical Engineering

SIR:—I notice with interest what you say in the Jan. 10 issue about methods of making sodium sulphide. There is no real difficulty in making a high-grade product provided the proper furnace be used and it have proper firing. Under these conditions a fused product with very little remaining sulphate may be obtained in a short time. The real difficulties are twofold: First, the temperature necessary is so high that about 5 per cent of the charge volatilizes. Second, the fused sulphide attacks the furnace lining rapidly and destroys it. I have made hundreds of tons of this material by the processes outlined in your editorial and generally failed to get a product containing less than 4 to 6 per cent sulphate. Moreover, by fusing the materials in an atmosphere free from oxygen, so as to avoid reoxidation of the sulphide and giving a chance to the carbon to deoxidize the charge completely, no difficulty is encountered; neither is the fuel cost excessive, since raw bituminous coal is used in the most economical manner.

A combination of this method with the barium process offers the best possible economy, since the furnaced cake produced as above may then be dissolved in the somewhat dilute barium sulphide wash liquor, which must be evaporated in any event, giving strong solution for the production of crystal or concentrated sulphide. In boiling down the solution for either of these products the waste heat of the furnace may easily be used for the concentration. In these days of high and scarce fuel such economies spell the difference between a profit or a loss. EDWARD HART.

Art and Science of Leather Manufacture—III

BY F. L. SEYMOUR-JONES*†

Vegetable Tanning Consists in Treating the Prepared Hides and Skins With Extracts of Suitable Natural Materials, the Procedure Varying Somewhat Empirically With the Nature of the Stock and the Product Desired, as the Actual Mechanism Is Indefinite

THE preliminary wetwork in preparing the skins having been accomplished, the next process is that of tanning proper. It is difficult to find a satisfactory definition of "tannin." Broadly, a tannin is any substance which precipitates gelatin and converts hide into leather; this covers a wide range of organic and inorganic substances.

Vegetable tanning, one of the most ancient methods, is still that most widely practiced, though for many purposes it has been replaced by chrome and its supremacy in other directions is similarly being challenged. No definite cause for the formation and secretion of tannin by plants is known, though many theories have been suggested. Tannins may occur in roots, wood, bark, leaves or fruit, though not necessarily of the same nature in each part. It is very widely distributed in the vegetable kingdom.

VEGETABLE TANNING MATERIALS

Space will permit of only the more important sources of tannin being mentioned. Of barks, the old standard material was that from the oak, *Quercus robur* and other varieties, more particularly *Quercus prinus*, the chestnut oak, in the United States. The bark contains from 4 to 22 per cent of tannin, but 10 per cent may be considered a good average. It is best peeled in the spring, when the sap is rising, and should be stored under cover from rain. Most barks contain about 6 per cent of soluble non-tanning matter (non-tans), which includes a large percentage of sugar. It is therefore unsuitable for the manufacture of tanning extract, owing to the great liability to fermentation. The bark of the American chestnut oak, owing to its comparatively low non-tan content, is free from this defect, and excellent extract is made therefrom.

Oakwood, though containing only 2 to 4 per cent of tannin, is largely used for extract manufacture in Europe. The tannin is different from that in the bark and more nearly resembles that of the chestnut. The chief source of supply is Slavonia, now of the Jugo-Slav State, where the chips and waste lumber are utilized for making an extract of around 26 to 28 per cent tannin content.

One of the most important native American tanning materials of today is the true or Spanish chestnut, *Castanea vesca*. This is a tree of rapid growth, the main source being in and about the Appalachian Mountains. The air dry wood averages about 8 per cent tannin, and the bark, which is little used alone, about the same. Chestnut extract is made from the wood and bark combined as a rule, and will have a tannin content of 36 to 60 per cent. Large quantities are made not only in this country but also in France.

Formerly if not still the most important North American tanning material, the bark of the hemlock fir (*Tsuga canadensis*) is undoubtedly the most characteristic American tannin. The tree is widely distributed over the northern United States and Canada, from Pennsylvania to Alaska. The bark averages 8 to 10 per cent of a reddish tannin. Extract is also made from the hemlock, both solid and liquid varieties finding place in the market.

Other conifers are used to a lesser extent for tannin. The Norway spruce (*Abies excelsa*) is much used in Austria. It contains a large proportion of fermentable sugars, and hence swells well but tans only lightly. The larch (*Larix europæa*) is used somewhat in the British Isles for light leathers, giving a light-colored product of pleasant odor. The Aleppo pine (*Pinus halepensis*), the bark of which contains up to 25 per cent tannin, is largely used along the eastern Mediterranean littoral.

South America provides a largely used material in quebracho. The wood is extremely hard, has a specific gravity of about 1.3, and contains 25 to 28 per cent of a difficultly soluble tannin. The tree grows in scattered groups over much of the Argentine, Chile and Paraguay. Much of the wood is extracted on the ground before export, but part goes to extract plants in this country, Germany, France and England. The difficultly soluble tannin is sometimes rendered more soluble by treatment with alkaline bisulphites or alkalis, which are subsequently neutralized. Such extracts are spoken of as sulphited quebracho. Even the insoluble tannin, however, if suspended in water and agitated with hide, will tan, showing that it is in reality soluble, though with difficulty.

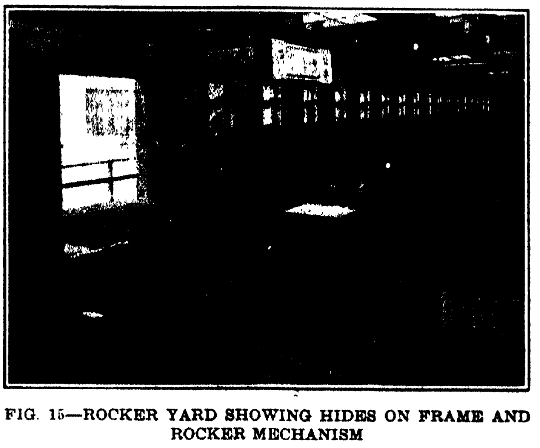

FIG. 15—ROCKER YARD SHOWING HIDES ON FRAME AND ROCKER MECHANISM

*Frank L. Seymour-Jones is the son of Alfred Seymour-Jones, of Wrexham, Wales, who for many years has been one of the foremost tanners of Great Britain and one of the leading scientists of the industry. Frank Seymour-Jones was graduated from the University of Leeds, England, with honors in applied chemistry of leather manufacture, being awarded the Le Blanc medal for special distinction. He now holds the Goldschmidt fellowship at Columbia University, where he is continuing fundamental research on tannery processes.

†Article I of this series appeared in *Chem. & Met.*, vol. 27, No. 23, Dec 6, 1922; Article II in vol. 27, No. 26, Dec. 27, 1922.

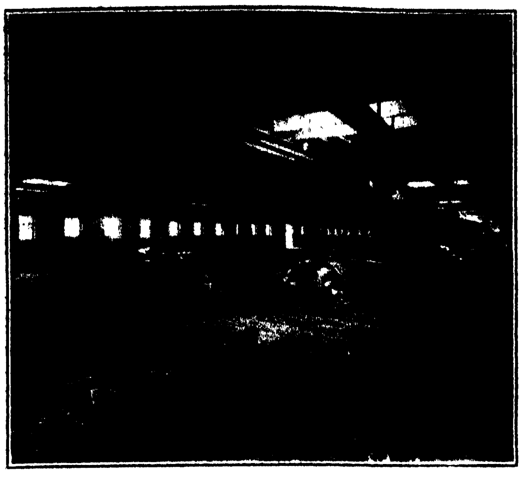

FIG. 16—LAYAWAY YARDS

The acorn cups from the valonia oak (*Quercus aegilops* and other species) form a highly important source of tannin. The small tree is widely spread through western Asia Minor, Greece and the Grecian archipelago, the best quality coming from Smyrna. The tannin content varies from 20 to 40 per cent. The "beard" (the spiky portion surrounding the cup) contains more tannin than the cup proper, and is often sold separately.

Galls occur chiefly on *Quercus infectoria* and other oaks; they contain up to 60 per cent of gallotannin. They are of very little use for tanning, but form the chief source of the tannic acid of commerce and pharmacy.

Sumach is obtained from Sicily (*Rhus coriaria*) and to a lesser extent from Virginia and the Southern States (*Rhus glabra, R. typhina* and other varieties). The leaves and small twigs of the bush are used, dried and ground in a primitive fashion with edge-runners. The tannin content of the Sicilian varieties averages about 25 per cent, that of the American 10 to 18 per cent. Few materials are adulterated more, chiefly with leaves of other and similar plants containing much less tannin; in fact, *Pistacia lentiscus* is imported from Algeria to Sicily for this purpose. Adulteration is easily detected by microscopical examination, with suitable treatment of the leaves. Sumach is chiefly used for light leathers, and gives a light-colored product. It is the best material known for bookbinding leathers, where wear and resistance to gas fumes and city atmosphere are desiderata.

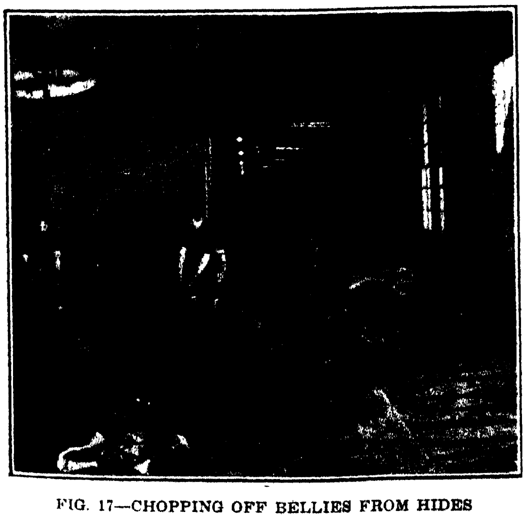

FIG. 17—CHOPPING OFF BELLIES FROM HIDES

Gambier is a solid or pasty extract obtained from the leaves and twigs of an East Indian shrub, *Nauclea* (or *Uncaria*) *gambir*. It is also known as terra japonica and, in common with various other extracts, as catechu. Until recently the manufacture was entirely in native hands and was crude in the extreme. The leaves and twigs are boiled in open pans until a sirupy liquid is obtained; this is roughly strained and poured out to set. It is exported either as paste, roughly covered with sacking, or in dry cubes of about a cubic inch size. The cube gambier contains 50 to 65 per cent tannin, and the pasty block gambier 35 to 40 per cent.

The mangrove grows on almost all marshy tropical coasts and comprises various species of *Rhizophora*. The bark contains 15 to 40 per cent tannin. It is a material of growing importance, and gives a deep red colored leather.

Myrobalans, the unripe fruit of *Terminalia chebula* and other East Indian species, contains 30 to 40 per cent tannin in the nut. The stones and kernels of the nut contain no tannin.

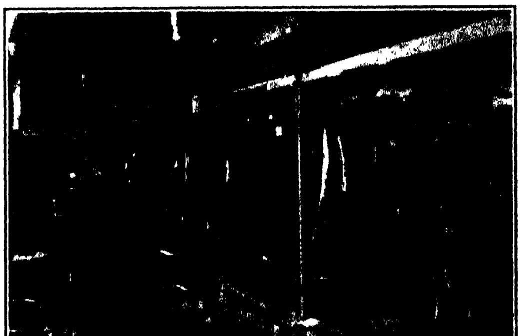

FIG. 18—BLEACHING VATS FOR REMOVING SURFACE TAN

Various kinds of acacias and mimosas are largely used, and those known as wattles are of rapidly growing importance. Indigenous to Australia, they have been transplanted to Natal, where a large and flourishing extract industry now thrives. The tree is of rapid growth and the bark contains up to 50 per cent tannin, according to species, though 30 per cent may be taken as a good average. In recent years it has also been developed in Kenya (British East Africa), where the tree reaches maturity for stripping in as short a time as 5 years. Another variety, *Acacia arabica*, is widely used in India and the Near East under the name "babool." I found it in use in Palestine 4 years ago and it may well have been the material of "one Simon, a tanner."

Divi-divi (*Cæsalpina coriaria*) and algarobilla (*C. brevifolia*), two Central American trees, provide tannin in their seed pods, which contain 40 to 45 per cent.

Among other natural tannins of lesser importance may be mentioned the saw palmetto (*Sabal serrulata*) of Florida, a tannin extract being made from its roots, and canaigre (*Rumex hymenosepalum*), a dock growing

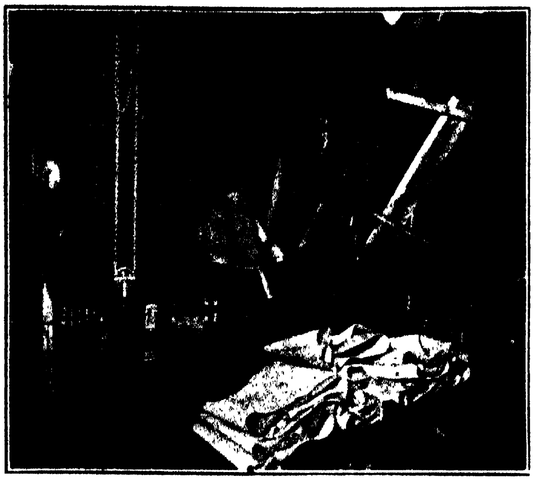

FIG. 19—OIL WHEELS

in Arizona, Mexico and southern California, the air dry roots of which contain 25 to 30 per cent tannin, together with a large quantity of starch.

Sulphite cellulose is obtained by concentrating the waste liquors from the manufacture of wood pulp by the sulphite process. It is not a true tanning material, but has found many applications in tanning, particularly in brightening the color and in filling (giving solidity to) sole leather. One firm markets this product as "spruce" extract. True spruce extract is often sold as "larch" extract.

The chemistry of the tannins is as yet little understood. Emil Fischer succeeded in synthesizing what was at least a stereo-isomer of gallotannin, and which was a penta-m-digalloyl-glucose. Freudenberg is continuing his work, and classifies tannins broadly into (*a*) tannins hydrolyzable with enzymes (tannase and emulsin), in which the benzene nucleus is linked to a larger complex by oxygen atoms, and (*b*) condensed tannins, in which the nuclei are linked by carbon atoms. The first class comprises (1) depsides (esters of phenolcarboxylic acids with each other or with other hydroxy-acids), (2) esters of phenolcarboxylic acids with polyhydric alcohols and sugars (gallotannin type), and (3) glucosides. Of more practical interest to the tanner is the old and rough classification into pyrogallol

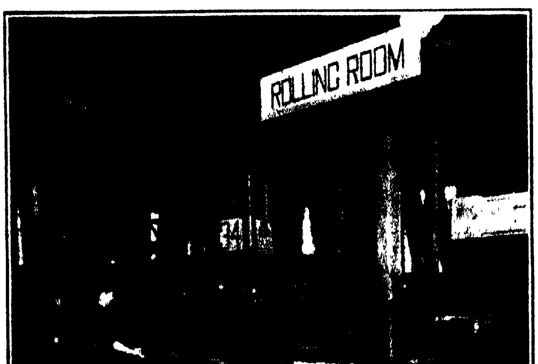

FIG. 20—ROLLING LEATHER FOR FINISH

and catechol tannins, according to their derivation. The pyrogallol tannins yield "bloom" (a deposit of ellagic acid) on fermentation or hydrolysis, while the catechols give insoluble "reds" or phlobaphenes. Some tannins—e.g., oak bark—appear to be of mixed origin, and give the characteristic reactions of both groups. Gallotannin, sumach, oakwood, chestnut, myrobalans, valonia, dividivi and algarobilla belong to the pyrogallol group, and the catechols include pine barks, hemlock, larch, acacias (mimosa, wattle), quebracho, mangrove, canaigre and gambier.

Synthetic tannins or syntans bear no chemical relationship to the natural tannins. The original syntan, Neradol D, was a condensation product of cresol-sulphonic acids with formaldehyde, and this general principle has been widely followed in the overwhelming list of patents granted for the preparation of such substances. Used alone, they are of little value, but in conjunction with natural tannins have found wide applications. They are particularly useful in the preliminary coloring of leather and in the final bleaching or brightening of color.

Extract Manufacture

The grinding of tanning materials prior to leaching varies with the nature of the material and the leaches used. The product must be sufficiently fine to leach

FIG 21—APPLYING POLISH TO GRAIN

easily and completely, yet not so fine as to clog the leaches and cause incomplete extraction of tannin. Various types of mills are employed, with steel blades or teeth to cut and rasp the materials. Disintegrators are widely used. Crushers are used for fruits such as myrobalans. The ground material is conveyed to the leaches by some form of mechanical conveyor—belt or bucket. The heat and dust developed during grinding are very great and cause a large fire hazard. Consequently it is usual, where tanneries grind some of their own materials, to locate the grinding machinery in a building apart from the main factory. Iron from the grinding machinery is very objectionable in the tan liquors, since it forms ink.

The ordinary battery of leaches consist of a series of pits or tubs provided with false bottoms and with an eye in each connecting to the next leach. The extracting water, heated as desired, is passed through these in turn, flowing from one to the next by gravity

FIG. 22—SETTING OUT MACHINE FOR SMOOTHING OUT GRAIN

FIG. 24 ROLLING HEAD MACHINES

or being pumped. The fresh water passes through the nearly spent tan, then on to the next, and through the series to the fresh material. Cold extraction gives a lighter and brighter colored liquor, while hot (not necessarily boiling) water extracts more tannin. The majority of tanning materials yield most tannin at 80 to 90 deg. C., but some, like sumach, canaigre and valonia, extract most at 50 to 60 deg. C.

In extract manufacture and in some tanneries the liquors are concentrated by evaporation, in evaporators of the triple effect or climbing film types. Evaporation is completed in vacuum pans, until the well-stirred liquor is sufficiently sirupy to solidify on cooling. Both solid and liquid extracts are largely made. The former offer economy in transit charges, but are not always so satisfactory in getting back into solution again. Extraction at high temperatures causes a darkening of color of the extract, and where necessary extracts are decolorized by the use of blood albumen, coagulated by heating the liquor or by some other suitable absorbent. Naturally this causes some loss of tannin, but since the leather buyer purchases largely on color, the tanner must demand light-colored extracts from the extract manufacturer.

Tannage proper consists in working the skins through

FIG. 23—JACKING THE HEADS

a series of tan liquors of gradually increasing strength. The strength of tan liquors is usually expressed in degrees barkometer. This instrument is merely a hydrometer, and affords a rough means of gaging the strength of liquors. One deg. Bkr. is equal to 1.001 specific gravity, 10 deg. Bkr. to 1.010 sp.gr., and 100 deg. Bkr. to 1.100 sp.gr., etc.

The materials, liquors and methods used vary according to the class of skins and the nature of product desired. For sole and belting leather, where the product is sold by weight, a heavy tannage is required, while for light leathers, sold by area, a sufficient but not excessive tannage is given.

Tanning Procedure

Taking sheep as typical of light stock, the first process is coloring. The color of the product is largely determined by the first early tannage. The skins are therefore paddled in a weak sumach (or other suitable) liquor, which will insure a light-colored product. Subsequent tannage may be by suspension in pits with periodical handling of the skins or agitation of the liquor, or paddling, or drumming. Naturally the two latter are more rapid, but if too violent loosen the skins out excessively. The strength of the liquors must be increased only gradually. If too strong and astringent liquors are used at first, the grain of the skin becomes drawn and case-hardened, and prevents the further penetration of tannin into the interior of the skin. Many materials are used in tanning, but for the finer classes of leather pyrogallol tannins are preferred, notably sumach, oak bark and wood, chestnut and larch.

The tanned skins are nailed on boards to dry in heated sheds, or may pass through a tunnel drier. They are then wet back and shaved. Shaving consists in reducing the skin to an even thickness by paring off on the flesh side, either by hand with a knife with a turned edge, or by machine, with a rapidly revolving spiral blade roller pressing the skin against a rubber roll. The skins then pass to dyeing and finishing.

Sheepskins are naturally extremely greasy and are therefore usually degreased. This is accomplished either by hydraulic pressing between brass plates after coloring, or by extraction with naphtha after tanning and dyeing, but before finishing. The naphtha is recovered. The grease finds a market for the manu-

facture of stuffing greases and similar products. The fire risk of a spirit degreasing plant is very high, and special precautions have to be taken to prevent any sparking of machinery, even belts being protected by points to avoid electrical sparks.

With heavy leather (sole leather, etc.) the hide commences in the suspenders, a weak but acid liquor, to insure complete neutralization of lime and good plumping, being used to color the leather. They pass to the rockers or handlers, through a series of liquors of increasing tannin content, where the suspended hides are rocked mechanically to insure even tannage. Next they go to the layers or dusters, where the hides (or bends) are placed horizontally in a pit, a layer of ground tan is dusted over the hide, another hide placed on top, and so on until the pit is full. The pit is then filled up with strong liquor. The hides pass through a series of these layaways. When tannage is completed—which may take from 3 to 6 months, although the hides are half tanned in 10 to 14 days—the leather is dipped in warm water to clean it, swabbed over with cod oil, dried, damped back and piled to samm (semi-dry), oiled on the grain, and rolled with a brass roller.

After tannage proper it is usual to fill the leather to get firmness and weight. The sides are dipped or drummed in a strong, hot, neat, tannin extract or sulphite cellulose. They are then bleached, by dipping into hot water, soda, dilute sulphuric acid, and water in turn. They pass through a wringer, and are next loaded. Loading is straight adulteration, necessary to get weight to sell at a competitive price. It cannot be said to affect the wearing quality of the leather adversely, but the deliquescent nature of some of the substances used renders the leather readily water-absorbent, and its harmful nature is obvious. Some countries, notably Australia and Sweden, have taken action to prevent the import of loaded leather. The usual substances are glucose, epsom salts (magnesium sulphate) and barium sulphate. The first two are drummed in with oil, while the last is implanted by alternate dippings in sulphuric acid and barium chloride.

The sequence of operations at the J. H. Ladew Co for tanning and finishing sole leather is illustrated by Figs. 15 to 25. As will be noted in Figs. 15 and 16, the hides are handled in the rocker and layaway yards by means of a monorail hoist. The use of an electric traveling crane for this purpose is shown in Figs. 26 and 27.

Many rapid tannages for sole leather have been tried, usually consisting in drumming the goods in concentrated liquors after a short preliminary coloring in weaker liquors. This is in general unsuitable for sole leather, as it is impossible to get the necessary firmness

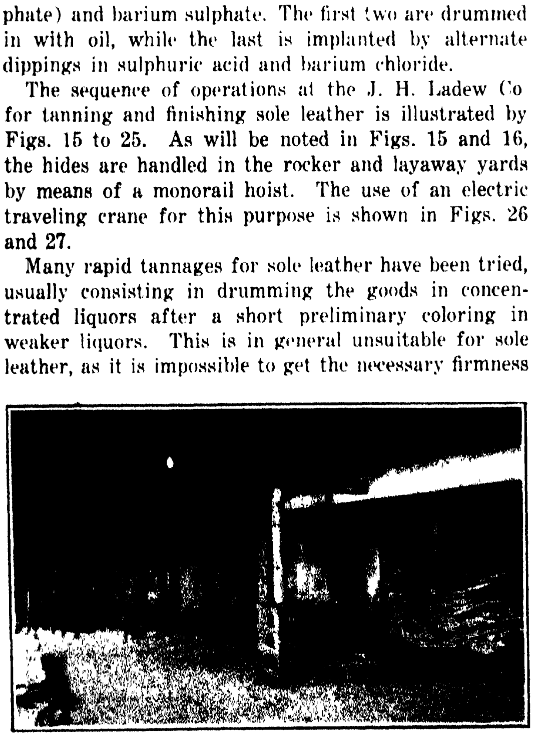

FIG. 25—DRYING LEATHER

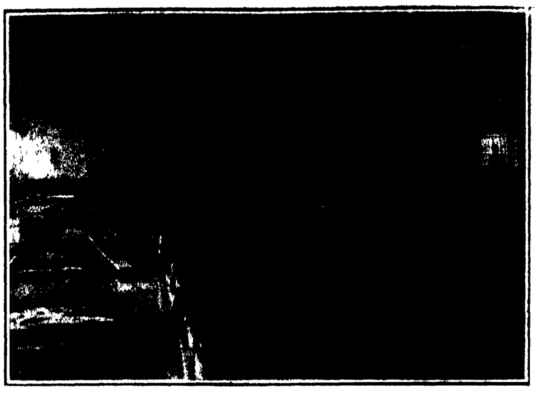

FIG. 26—ROCKER YARD WITH ELECTRIC TRAVELING CRANE

and solidity by a straight drum tannage. Used in conjunction with suspension methods, it has met with some success.

One method of vacuum tanning has achieved some popularity, though not yet employed very extensively—namely, that known as the Nance process. The difficulty in any vacuum tannage is that, for the tan liquor to enter the hide, the pressure must be so reduced that the water in the hide capillaries boils out, leaving a vacuum. This the Nance process accomplishes. The liquors used are then introduced at about 25 deg. C., and rapidly penetrate the hide.

Many materials are used in heavy leather tannage, hemlock, chestnut and chestnut oak extracts being favorites. In the layers, for dusting materials, valonia, algarobilla, and ground bark are used. When pyrogallol tans are employed, the bloom deposited on the grain may either be left on or removed by scouring, according to the type of product required by the buyer.

Belting and other leathers are usually curried—i.e., stuffed with greases to render them waterproof—and then finished. The bloom is scoured off by machine, the hides are skived or shaved and then stuffed. Stuffing is carried out either by hand or in the drum. A suitable mixture of cod oil, tallow and stearine is applied to the damp leather. The stuffed leather is "set out"—i.e., stretched out flat and all wrinkles removed, either by hand or machine. Belting leather is finally stretched by machine. Stuffing is often carried out hot, a temperature of 90 deg. C. or over being used. In this case the leather must be absolutely dry before entering the drum or it will be seriously damaged. In passing it may be remarked that dry leather will stand much higher temperatures than wet, and that chrome-tanned stands heat better than vegetable-tanned. Since the tanner takes days to dry his hides, it is scarcely reasonable to expect to dry a pair of wet boots satisfactorily by a hot radiator in an hour or so.

The choice of materials and their blending to produce the desired effect in any kind of vegetable tanning is an art in itself and also requires knowledge of the constituents. The soluble extract from any tanning material contains a greater or less proportion of non-tans, part of which consists of readily fermentable sugars. These yield acids, which tend to plump the leather. A high tan:non-tan ratio in a material means a highly astringent liquor, such as straight quebracho, while the greater the proportion of non-tans the milder and mellower the liquor. Gambier is an example of a mild material. Even such a highly astringent material as

FIG. 27—LAYAWAY YARD WITH ELECTRIC TRAVELING CRANE

quebracho can be rendered as mild as gambier by addition of suitable non-tans.

Molds are an occasional source of loss in tan liquors. Their action is due to the secretions of an enzyme, tannase, which hydrolyzes certain classes of tannins. At the same time the molds utilize the tannin as a source of carbon nutriment, where other carbonaceous matter is absent.

There are many theories of vegetable tanning, none yet susceptible of exact proof. They range from pure physical adsorption of the tannin by the hide fibers to a definite chemical combination between hide protein and tannin. One very plausible theory holds that the negatively charged tannin particles and the positively charged hide (on the acid side of its isoelectric point) mutually precipitate each other, just as in the mutual precipitation of colloids. Unfortunately for this, it is quite possible to tan hide in an alkaline solution, so it will require some modification. Needless to say, alkaline tanning is entirely impracticable, since large excess of tannin has to be used, though it is definitely fixed by hide powder. One thing is certain—that combination between hide and tannin is slow and not immediate. Freshly tanned hide powder loses its tannin if extracted *wet* with alcohol, but not after drying. The tannin can be easily stripped from *freshly* tanned hide powder with alkalis, but not after the tanned hide powder has been aged for some time. The whole subject is as yet too indefinite to make any detailed statements of value, and it will be necessary to wait until more is known of the chemical nature of tannins and hide before a definite explanation can be adduced.

Developments and Tendencies in the German Potash Industry*

Stassfurt Giving Way to Hannover and South Harz District—Production and Sale—Government Control—French Competition

BY WILLIAM T. DAUGHERTY
Assistant Trade Commissioner, Berlin
U. S. Bureau of Foreign and Domestic Commerce

THE war left to Germany at least one self-contained industry—the potash industry. The pre-war monopoly enjoyed by Germany, broken by the loss of the potash mines in Alsace Lorraine under the peace treaty, is nevertheless not as seriously threatened now as the first signs after the war would have seemed to indicate. The superiority of German deposits i.e., the purer and more abundant deposits of salts and the simultaneous occurrence of carnallite ($KCl.MgCl_2.6H_2O$), sylvanite ($xKCl.yNaCl$), kainite ($K_2SO_4.MgSO_4.MgCl_2.6H_2O$), kieserite ($MgSO_4.H_2O$)—as well as lower costs of production, favors Germany on the world market. Germany's expectation of setting a record of sales in the calendar year 1922—i.e., probably around 1,330,000 tons of potash (K_2O), or 220,000 tons more than in 1913, out of which total 24.8 per cent has been for foreign sales in the first 10 months of 1922 (against 45 to 50 per cent in 1913)—seems to confirm this claim. Energetic plans are in progress to penetrate America and recover Germany's most important pre-war market.

SHIFTING OF PRODUCTION CENTERS

Production centers of the German potash industry are roughly five—namely: (1) The Hannover district, (2) the South Harz district, (3) the Werra (Thuringia) district, (4) the Stassfurt district and (5) the Halle, Mansfeld and Unstrut district, in the order of their approximate production in terms of K_2O in the first 6 months of 1922. In October, 1922, 128 shafts were being actively worked in all Germany, while 83 shafts were idle, according to the "Kaliprüfungsstelle," of Berlin, an official organization, calculating the participation of all German works in total sales.

Rich and abundant supplies of German potash, lying near the surface, or more profitably worked for richer content if lying deeper, permit a variety of choice of location for new works. The shifting, for instance, of production centers within the past year, so that the famous Stassfurt district, which occupied second place in production in 1921, fell to fourth place during the first 6 months of 1922, is proof of the growing importance of the South Harz district.

This shifting of production centers is not necessarily borne out by the number of active shafts in operation, as some shafts in respective districts are worked more intensively than others. In October, 1922, the Hannover district operated the largest number of shafts—namely, 54 shafts out of 79; the South Harz district, 24 out of 33; Stassfurt, 24 out of 43; the Werra, 14 out of 27; Halle, etc., 12 out of 29.

PRODUCTION AND SALES

Production.—Production of all crude salts by districts in the years indicated is shown in Table I.

The potash content from this production is shown in Table II.

*Abstracted from a special report, received Jan. 17, 1923, by Western European Division, Bureau of Foreign and Domestic Commerce, Department of Commerce.

Sales.—Table III shows the total sales of German potash salts, in terms of K_2O content, to inland and foreign purchasers in the years indicated. It is observed from this table that except for the year 1921 foreign sales have increased progressively in post-war years. Germany's best customer for potash salts in 1913 was the United States, with purchases of 236,884 tons of K_2O; Holland came next, purchasing 43,478 tons, while France bought 33,115 tons. Although foreign sales have decreased in volume in post-war years, the same relative importance of these markets is probably not appreciably changed, as, for instance, figures for 1920 show. In that year the United States bought 83,602 tons of K_2O from Germany; Holland, 54,347 tons; England, 11,414, and France, 1,975, according to figures given by the German Potash Syndicate.

Potash Control in Germany

After various experiments to regulate production and sales of potash extending over a period of about half a century, the German Reichstag passed the so-called federal potash law on May 25, 1910. This law provided that the government, and not the Potash Syndicate, be empowered to fix inland prices for potash. It also took from the syndicate the right to prescribe the amounts of participation of the various concerns (groups) in total sales, and created a so-called "distribution center" (Verteilungsstelle) for this purpose. At the same time, however, an appeal commission was created with power to hear appeals against decisions of the distribution center. The real organization of the Potash Syndicate was not directly affected by this law. This organization was regulated through the members, as well as through the sales agreement. Until the outbreak of the revolution (November, 1918), the organization was not changed.

Socialist parties with majority votes in the Reichstag after the revolution contemplated the socialization of Germany's potash resources. As this proposal was confronted with too many difficulties, another alternative was chosen—namely, the creation of a federal potash council (Reichskalirat) with power to control the German potash industry.

The Federal Potash Council is composed of thirty members, and includes representatives of the potash producers, dealers and wholesale consumers (agriculture and the chemical industry). In addition, three members of the Potash Syndicate are admitted, as well as one expert in potash mining. Employers and labor are represented in equal number in the council.

Along with the council are other bodies, such as the "Kaliprüfungsstelle," already mentioned, and the appeal office. Both of the latter perform the same duty as was written into the law of 1910 for the distribution center and the appeal commission. The potash producers themselves are organized into a sales organization, which is the Potash Syndicate, which alone has the right to sell potash at home and abroad.

Importance of German Monopoly

Until the end of the war Germany had, *de facto*, a potash monopoly. This monopoly was partly broken by the granting of approximately thirteen potash shafts to France in connection with the cession of Alsace-Lorraine. At that time the thirteen shafts were not all in operation, but they were rapidly improved and thrown into competition with German production. Alsatian competition is, however, probably handicapped by the existence of far fewer mines and concentrating plants, as well as a none too great occurrence of sulphate salts. Kieserite ($MgSO_4$), used in Germany in the production of potassium sulphate and potassium-magnesium sulphate, is absent completely from Alsatian deposits.

In order to overcome this handicap, attempts have been made to employ sulphuric acid on potassium chloride, but the production costs are said to be too great to permit profitable competition. The occurrence of clay in Alsatian deposits is said to offer another disadvantage in the most profitable concentration of the raw salts. Freight competition is another factor to be taken into consideration. The distance to nearest harbors—namely, Antwerp and Rotterdam—is greater than from German mines to Bremen and Hamburg.

The German industry is apparently not greatly concerned over the new French competition. French exports of potash to the United States are roughly estimated by German authorities as not exceeding 20 per cent of all sales to our country, but it is claimed that the French are selling at a loss (with possible subsidies), and that competition will diminish, on account of inability to compete with German prices. The contention regarding the subsidy of the French industry cannot be verified here, but it is vigorously denied in official French quarters in Berlin.

Negotiations between Alsatian and German producers have been attempted with a view to agreeing upon a uniform price policy, but without success, and the present prospect is that Germany will probably continue to underbid French producers. If German claims are justified, the German control of the international potash trade appears to be not very seriously affected by the separation of the Alsatian potash mines.

Fundamentals of Rectification

Conditions for Perfect Rectification of Binary Mixtures

The Relations Existing in a Simple Adiabatic Rectifier Are Discussed and the Possibility of Perfect Rectification Is Analyzed—Special Case of Proportionality Latent Heats

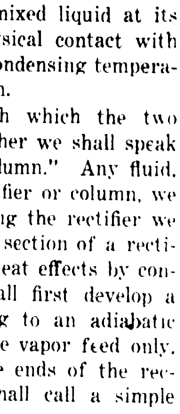
BY C. C. VAN NUYS
Chief Physicist, Air Reduction Co., New York City

THE term rectification, as commonly used, refers to a variety of operations or processes wherein either evaporation or condensation or both are employed to purify or change the composition of physical mixtures. In the following pages, however, the term is understood in general to refer to the interaction between a continuous stream of a mixed liquid at its boiling temperature in intimate physical contact with a continuous stream of vapor at its condensing temperature flowing in the opposite direction.

The conduit or passages through which the two streams flow in contact with each other we shall speak of collectively as a "rectifier" or "column." Any fluid, liquid or vapor, as it enters the rectifier or column, we shall call a feed, and any fluid leaving the rectifier we shall call a product. Any portion or section of a rectifier which is insulated from outside heat effects by conduction is called adiabatic. We shall first develop a series of general equations applying to an adiabatic rectifier with one liquid feed and one vapor feed only, these two feeds entering at opposite ends of the rectifier. Such an arrangement we shall call a simple rectifier.

EQUATIONS FOR A SIMPLE RECTIFIER

Suppose a continuous stream of a liquid mixture of two components enters the top of a rectifying column wherein for convenience it may be assumed to cascade over a large number of "trays" of the usual form, and suppose that this liquid as it descends is in intimate physical contact with an ascending saturated vapor which enters the rectifying column at the bottom.



Assume that the system is perfectly insulated, and let the fractional composition of the liquid feed in the more condensible component be x_1, and let the mass of liquid entering the column per unit time be M_1. Let the fractional composition in the same component of the vapor feed be y_2 and the mass thereof entering the column per unit time be m_2. Let the composition of the vapor leaving the top of the column be y_1 and the composition of the liquid product leaving the bottom be x_2. Then the following equations must hold in all cases. In these equations m_1 is the mass of vapor leaving the top of the column and M_2 is the mass of liquid leaving the bottom and the unit of mass may be taken either as 1 gram or as 1 gram molecule, or mol. If the mol is the unit of mass, compositions must be taken as molecular compositions—i.e., fractional compositions by volume when the mixture is in a condition approaching that of a perfect gas.

In the first place the total mass of the fluids entering the column must be equal to the total mass of the fluids leaving. Hence,

$$M_1 + m_2 = M_2 + m_1$$

Second, a similar relation holds for the masses of the more readily condensible component—i.e.,

$$x_1M_1 + y_2m_2 = x_2M_2 + y_1m_1$$

Third, the sum of the values of the "total heat" function for all fluids entering the apparatus must equal the same quantity for the fluids leaving—i.e., if I_1 is the total heat per unit mass of the liquid M_1, and I_2 the same quantity for the liquid M_2, and J_1 and J_2 the corresponding quantities for the vapors m_1 and m_2, the following equation holds:

$$I_1M_1 + J_2m_2 = I_2M_2 + J_1m_1$$

From these three equations any three of the four masses, say M_2, m_1, m_2, may each be determined in terms of the total heats I_1, I_2, J_1, J_2 the compositions x_1, y_1, x_2, y_2 and the remaining mass, say M_1.

The "total heats," I_1, I_2, J_1, J_2, are, in all cases, determined by the physical properties of the corresponding fluids and hence cannot be regarded as independent variables. Since we have three equations among the remaining eight "variables," x_1, M_1, x_2, M_2, y_1, m_1, y_2, m_2, we may regard any five of them as independent—i.e., their values may be stipulated or assigned in advance, and then the three remaining are determined by the above equations.

Of the five independent variables, however, among which must be included at least one of the quantities x_1, y_1, x_2, y_2, there is always one composition at least that is determined by conditions in the rectifier of which the above equations take no account. The basis of this statement will appear as we proceed.

Solving our system of equations for M_2, m_1 and m_2, we obtain:

$$M_2 = \frac{(J_1 - I_1)\ (y_2 - y_1) + (J_2 - J_1)\ (x_1 - y_1)}{(J_2 - I_2)\ (y_2 - y_1) + (J_2 - J_1)\ (x_2 - y_2)}\ M_1$$

$$m_1 = \frac{(J_2 - I_1)\ (x_2 - x_1) + (I_2 - I_1)\ (x_2 - y_2)}{(J_2 - I_2)\ (y_2 - y_1) + (J_2 - J_1)\ (x_2 - y_2)}\ M_1$$

$$m_2 = \frac{(J_1 - I_1)\ (x_2 - x_1) + (I_2 - I_1)\ (x_1 - y_1)}{(J_2 - I_2)\ (y_2 - y_1) + (J_2 - J_1)\ (x_2 - y_2)}\ M_1$$

Now in assigning values of the variables x_2 and y_1, these being the compositions of our products, we must take account of certain limitations. For example, it is impossible to produce a liquid M_2 whose composition x_2 differs more widely from the composition y_2 of the vapor m_2 than does the composition of that liquid which would have phase equilibrium with the vapor m_2. That is, the maximum possible value of x_2 is x_{y_2}, the composition of a liquid in phase equilibrium with the vapor y_2. Similarly, the minimum possible value of y_1, the composition of the vapor product, is y_{x_1}, that of the vapor having phase equilibrium with the liquid x_1.

If we assume perfect contact between liquid and vapor

in the column, we may suppose that x_2 and y_1 can attain these values. Then if m_2 be taken as less than the value fixed by the above three equations under these conditions, x_1, y_2 and M_1 being kept constant, the composition y_1 of the vapor leaving the top of the column will still be the composition for phase equilibrium with the incoming liquid, but the composition x_2 at the bottom will decrease—i.e., we shall obtain a liquid product whose composition in the more condensible component is less than that for phase equilibrium with the incoming vapor. If, on the other hand, m_2 be made larger than the value fixed by the three equations just written, the composition x_2 will still be that for phase equilibrium with the incoming vapor y_2, while the composition y_1 of the vapor product will increase—i.e., we shall obtain a vapor whose composition in the more condensible component is greater than for phase equilibrium with the incoming liquid.

The equation for M_2 may be written in the form:

$$\left[J_1 - I_1 + (J_2 - J_1)\frac{x_1 - y_1}{y_2 - y_1}\right]M_1 = \left[J_2 - I_2 + (J_2 - J_1)\frac{x_2 - y_2}{y_2 - y_1}\right]M_2$$

This equation may be regarded as defining equivalence between the liquid M_1 admitted at the top and the liquid M_2 obtained at the bottom.

In the particular case where $x_2 = y_2 = 1$, $x_1 = y_1 = 0$, it takes the form:

$$(J_1 - I_1)\,M_1 = (J_2 - I_2)\,M_2$$

In this case, however, since each one of the fluids M_1, M_2, m_1, m_2, contains only one component, the quantities $J_1 - I_1$ and $J_2 - I_2$ are the latent heats of evaporation in the pure condition of the two components respectively, and the last equation may be written:

$$L_A M_1 = L_B M_2$$

where L_A is the latent heat of the more volatile component and L_B is the latent heat of the more condensible component. For two substances for which $L_A = L_B$, the last equation would become:

$$M_1 = M_2$$

In the equation

$$\left[J_1 - I_1 + (J_2 - J_1)\frac{x_1 - y_1}{y_2 - y_1}\right]M_1 = \left[J_2 - I_2 + (J_2 - J_1)\frac{x_2 - y_2}{y_2 - y_1}\right]M_2$$

we note that each of the quantities $J_1 - I_1$ and $J_2 - I_2$ is the difference between the total heat per unit mass of a liquid mixture and that of the vapor in phase equilibrium with it.

These quantities constitute much the larger part of the respective coefficients of M_1 and M_2, since $J_2 - J_1$ is the difference of the total heat per unit mass of two saturated vapors at the same pressure, and the fractions

$$\frac{x_2 - y_2}{y_2 - y_1},\ \frac{x_1 - y_1}{y_2 - y_1}$$

approach zero as the end products approach 100 per cent purity—that is, as $x_2 = y_2 = 1$, and $x_1 = y_1 = 0$.

In general, whatever the compositions x_1, y_1, x_2, y_2, if it should happen that $J_1 = J_2$ and $I_1 = I_2$ we have:

$$M_2 = M_1$$

and

$$m_1 = m_2 = \frac{x_2 - x_1}{y_2 - y_1}M_1$$

Consider next a level in the column where the composition of the descending liquid is x, x being greater than x_1 and less than x_2, and let the mass of descending liquid passing this level per unit time be M. Let the composition of the ascending vapor at this level be y, and the mass passing per unit time be m. Then it is clear that the composition y cannot be less than the composition of a vapor having phase equilibrium with the descending liquid of composition x.

At this point, however, under the conditions specified, the value of y may be determined as a function of x with the values of x_1, y_1, x_2 and y_2 as constants from the six following equations:

$$\begin{aligned}
M_1 + m_2 &= M_2 + m_1\\
x_1M_1 + y_2m_2 &= x_2M_2 + y_1m_1\\
I_1M_1 + J_2m_2 &= I_2M_2 + J_1M_1\\
M_1 + m &= M + m_1\\
x_1M_1 + ym &= xM + y_1m_1\\
I_1M_1 + Jm &= IM + J_1m_1
\end{aligned}$$

From all these equations all (M, m)'s may be eliminated and thus a relation be obtained between x and y containing the constants I_1, I_2, I, J_1, J_2, J, x_1, y_1, x_2 and y_2. Hence we conclude that if the ratio $x{:}y$ thus determined is everywhere equal to or less than the ratio for phase equilibrium, it is possible for the rectification to be complete or "perfect"—i.e., we can obtain a vapor at the top having phase equilibrium with the incoming liquid and at the same time obtain a liquid at the bottom having phase equilibrium with the incoming vapor. It the ratio between x and y is anywhere greater than that for phase equilibrium, it is impossible for the rectification to be complete unless either some liquid or some vapor be removed at some intermediate level or levels in the column. If the ratio is everywhere less than that for phase equilibrium, then a limited amount of liquid of composition x between x_1 and x_2 or a vapor of composition y between y_1 and y_2 may be added at a point between the top and bottom of the column without changing the composition of the vapor or of the liquid leaving it.

We have found above that the value of m_1 as obtained from the first three equations is:

$$m_1 = \frac{(J_2 - I_2)\,(x_2 - x_1) + (I_2 - I_1)\,(x_2 - y_2)}{(J_2 - I_2)\,(y_2 - y_1) + (J_2 - J_1)\,(x_2 - y_2)}\,M_1$$

Since the same relation holds at an intermediate point in the column, we have

$$m_1 = \frac{(J - I)\,(x - x_1) + (I - I_1)\,(x - y)}{(J - I)\,(y - y_1) + (J - J_1)\,(x - y)}\,M_1$$

Comparing this with the last equation written, we obtain as the necessary relation between the x's and y's in order for perfect rectification to be possible:

$$\frac{(J - I)\,(x - x_1) + (I - I_1)\,(x - y)}{(J - I)\,(y - y_1) + (J - J_1)\,(x - y)} = \frac{(J_2 - I_2)\,(x_2 - x_1) + (I_2 - I_1)\,(x_2 - y_2)}{(J_2 - I_2)\,(y_2 - y_1) + (J_2 - J_1)\,(x_2 - y_2)}$$

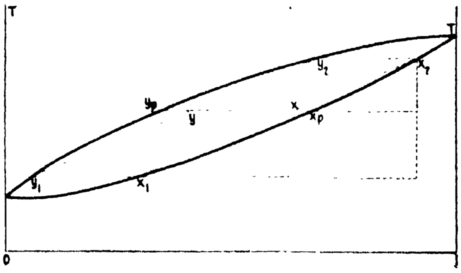
If the ratio $x{:}y$ determined by the last equation in terms of the various constants, x_1, x_2, y_1 and y_2, I, I_1, I_2, J, J_1, J_2, is greater than the ratio for phase equilibrium, the rectification is clearly impossible—i.e., we cannot obtain a vapor at the top having phase equilibrium with the incoming liquid and at the same time obtain a liquid at the bottom having phase equilibrium with the incoming vapor, since it is impossible at any level in the column for ascending vapor and descending liquid to differ in composition more widely than for phase equilibrium. The properties of those binary mixtures for which the ratio $x{:}y$ is everywhere less than the value for phase equilibrium and thus for which perfect recti-

fication, as we have exemplified it, is possible are made evident by considering the T-x diagram.

Consider the special case where $I_1 = I_2 = I$ and $J_1 = J_2 = J$. Under these conditions, the above relation between the x's and y's reduces to:

$$\frac{x - x_1}{y - y_1} = \frac{x_2 - x_1}{y_2 - y_1}$$

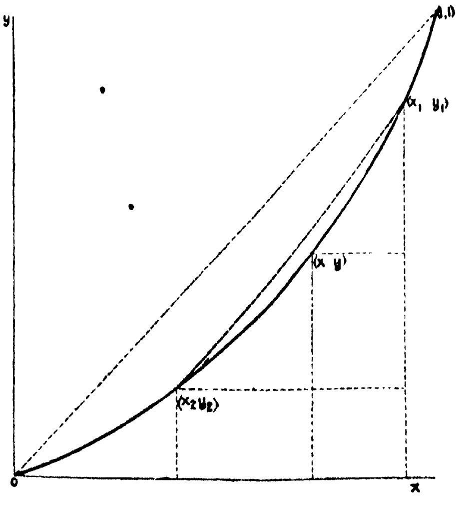
Let the values of the x's and y's be as indicated in the diagram. Then it is clear that if y lies on the straight line connecting y_1 and y_2, x must lie on the straight line connecting x_1 and x_2, since the segments on



each of a system of lines passing through a point intercepted between a system of parallel lines are proportional. Hence, we may conclude that under the assumed condition, $I_1 = I_2 = I$, and $J_1 = J_2 = J$, in order for the rectification to be impossible—i.e., for the difference between x and y to be greater than that for phase equilibrium—the lower boiling point curve must, at some portion of its length, be such that the horizontal distance measured *to the right* from the point x_p on the curve to the point x on the chord drawn from x_1 to x_2 is greater algebraically than is the corresponding quantity measured also to the right for the dew point curve—i.e., such that $x_px > y_py$, both distances being taken positive when measured to the right from the equilibrium curve.

If we confine the discussion to mixtures which do not possess a constant boiling composition between x_1 and x_2, these being the only mixtures for which perfect rectification is possible for all ranges of composition, then it follows from the foregoing result that for perfect rectification to be impossible (i.e., for the difference $x - y$ to be greater than $x_p - y_p$) either the dew point curve must contain inflexions between the points y_1 and y_2 or else the boiling point curve contains inflexions between x_1 and x_2.

If we consider a diagram in which values of x are abscissas and values of y are ordinates, the condition



$$\frac{x_2 - x_1}{y_2 - y_1} = \frac{x - x_1}{y - y_1}$$

implies that the point (x, y) lies on the line connecting the points (x_2, y_2) and (x_1, y_1) and hence between the points (x_1, y_1) and (x_2, y_2), the curve, which must be everywhere below the line defined by the points (0, 0) and (1, 1) contains two or more inflexions. In such a case, even though it would be impossible to obtain perfect rectification with the given end compositions x_1, y_1, x_2, y_2, still it would be possible to obtain perfect rectification if the end compositions were taken closer to 100 per cent purity respectively—i.e., if x_2 and y_2 were taken closer to 1, and x_1 and y_1 closer to zero—since as this condition is approached, it is impossible for (x, y) to lie on the line between (x_1, y_1) and (x_2, y_2) unless $x = y$, this latter being the condition for a constant boiling mixture.

The relation between x and y may be obtained in another form, which will be useful later, by properly changing subscripts in the solutions of our original three equations thus:

$$m = \frac{(J_1 - I_1)\ (x - x_1) + (I - I_1)\ (x_1 - y_1)}{(J - I)\ (y - y_1) + (J - J_1)\ (x - y)}\ M_1$$

and also

$$m = \frac{(J_2 - I_2)\ (x_2 - x) + (I_2 - I)\ (x_2 - y_2)}{(J_2 - I_2)\ (y_2 - y) + (J_2 - J)\ (x_2 - y_2)}\ M$$

but

$$M = \frac{(J_1 - I_1)\ (y - y_1) + (J - J_1)\ (x_1 - y_1)}{(J - I)\ (y - y_1) + (J - J_1)\ (x - y)}\ M_1$$

whence

$$m = \frac{(J_2 - I_2)\ (x_2 - x) + (I_2 - I)\ (x_2 - y_2)}{(J_2 - I_2)\ (y_2 - y) + (J_2 - J)\ (x_2 - y_2)}$$
$$\frac{(J_1 - I_1)\ (y - y_1) + (J - J_1)\ (x_1 - x_1)}{(J - I)\ (y - y_1) + (J - J_1)\ (x - y)}\ M_1$$

Comparing this with the first relation between m and M_1, we obtain

$$\frac{(J_1 - I_1)\ (x - x_1) + (I - I_1)\ (x_1 - y_1)}{(J_1 - I_1)\ (y - y_1) + (J - J_1)\ (x_1 - y_1)} = \frac{(J_2 - I_2)\ (x_2 - x) + (I_2 - I)\ (x_2 - y_2)}{(J_2 - I_2)\ (y_2 - y) + (J_2 - J)\ (x_2 - y_2)}$$

as an alternative form of the x, y relation.

PROPORTIONALITY LATENT HEATS

A particular case of considerable interest is that where we are dealing with two components having unequal latent heats but which have the property that the latent heat of evaporation L at constant pressure of any mixture of the two follows the proportionality law as indicated by the equation:

$$L = L_Bx + L_A\ (1 - x)$$

where x is the composition in the component whose latent heat at that pressure is L_B, the latent heat of the other component being L_A. This equation implies that the heat required to evaporate a given amount of either component present in a mixture under a constant total pressure is the same as it would be in the pure condition at that pressure. If, in addition to this peculiarity, the mixture has the further property that its "total heat" when in the saturated vapor state equals the sum of the total heats that the components therein contained would have if each one were in the saturated condition at that pressure, the above equations are somewhat simplified.

Let J_A be the total heat per unit mass in the satu-

rated state of the more volatile component, and J_B that of the more condensible component. Then, if J is the total heat per unit mass of a mixed saturated vapor of composition x, the property just described is indicated by:

$$J = J_B x + J_A (1 - x)$$

Let I_A and I_B be the corresponding total heats of the pure constituents when each one is liquid at its boiling point. Then the two properties above decribed necessitate that the proportionality law holds also for the total heat I of a mixed liquid at its boiling point—i.e.,

$$I = I_B x + I_A (1 - x)$$

If, now, in the equation we have obtained between M_1 and M_2 we substitute these expressions for the I's and J's, that equation becomes:

$$[(J_B - I_B)x_1 + (J_A - I_A)(1 - x_1)] M_1 = [(J_B - I_B)x_2 + (J_A - I_A)(1 - x_2)] M_2$$

or

$$[L_B x_1 + L_A (1 - x_1)] M_1 = [L_B x_2 + L_A (1 - x_2)] M_2$$

The last equation may be obtained directly by writing, in place of the third of our original equations, one which states that for a mixture having the properties specified the heat required to vaporize the mass of the more volatile component evaporated in the column equals the heat lost by the mass of the more condensible component liquefied at the same time—i.e.,

$$L_B(x_2 M_2 - x_1 M_1) = L_A[(1 - y_1) m_1 - (1 - y_2) m_2]$$

This, if combined with the first two original equations, becomes:

$$[L_B x_1 + L_A(1 - x_1)] M_1 = [L_B x_2 + L_A(1 - x_2)] M_2$$

and solving for m_1 and m_2, we have

$$m_1 = \frac{x_2 - x_1}{y_2 - y_1} \cdot \frac{L_B y_2 + L_A(1 - y_2)}{L_B x_2 + L_A(1 - x_2)} M_1$$

$$m_2 = \frac{x_2 - x_1}{y_2 - y_1} \cdot \frac{L_B y_1 + L_A(1 - y_1)}{L_B x_2 + L_A(1 - x_2)} M_1$$

while the relation between x and y at an intermediate point in the column is:

$$\frac{x - x_1}{y - y_1} \cdot \frac{L_B y + L_A(1 - y)}{L_B x + L_A(1 - x)} = \frac{x_2 - x}{y_2 - y} \cdot \frac{L_B y_2 + L_A(1 - y_2)}{L_B x_2 + L_A(1 - x_2)}$$

or

$$\frac{x - x_1}{y - y_1} \cdot \frac{L_B y_1 + L_A(1 - y_1)}{L_B x_1 + L_A(1 - x_1)} = \frac{x_2 - x}{y_2 - y} \cdot \frac{L_B y_2 + L_A(1 - y_2)}{L_B x_2 + L_A(1 - x_2)}$$

SUMMARY

1. In the above discussion we have developed a set of relations applying to a simple adiabatic rectifier or to any section of an adiabatic rectifier in which no material is admitted or withdrawn at any level except the top and bottom.

2. We have pointed out the limitations necessary to be taken account of in estimating masses and compositions of products obtainable from given masses and compositions of materials entering such a rectifier.

3. We have developed a necessary relation between compositions of liquid and vapor in contact at any level in such a rectifier and have shown for what type of binary mixture "perfect" rectification under these conditions is possible.

4. We have obtained the special form these various relations take for a mixture having the property we have called proportionality latent heat at constant pressure.

To be continued in a subsequent issue.

The Tariff Act of 1922 and the Chemical Industries

An Eminent Economist's Views on the Development of American Manufacture of Dyestuffs and Chemicals and That Industry's Relation to the Tariff

In the last number of *The Quarterly Journal of Economics*, its editor, Prof. F. W. Taussig, contributes a comprehensive chapter on "The Tariff Act of 1922." The former chairman of the United States Tariff Commission has made a piercing analysis of the provisions of this measure, particularly in the relation they bear to economic developments in the industries affected by them. Dr. Taussig's views on the chemical schedule will be read with interest by those who have followed the development of the American chemical industry and its efforts to obtain protective legislation.

AMONG the most hotly debated paragraphs were those fixing the duties on coal-tar products and dyestuffs.

They were closely connected with the administrative provisions of the act. The history of this set of duties makes a long story, and the economic situation is highly complicated. Only a brief sketch is possible here.

THE WAR ARGUMENT

The war argument was used to the limit. Before 1914 the supply of dyestuffs, the most important of the coal-tar products, came almost exclusively from Germany. During the war there had been a great shortage, speculation, advances in prices, a hothouse domestic industry. At its close, the domestic producers were dismayed, and urged their case before Congress and the public with great insistence. On the other hand, the circumstances that there were large-scale combinations in the industry and that the unpopular du Pont concern was among the most important producers aroused suspicion and some hostility.

Regarded from the strictly economic point of view the industry does not seem to be adapted to American ways. In our technical parlance, it lacks a comparative advantage. Its processes are painfully detailed and elaborate, in which highly trained and highly paid labor is applied slowly and carefully to a variety of products. Each one of these products is turned out in small amounts; a possible exception is synthetic indigo, of which there is something like mass production. In the main it is adapted to the German industrial ways and traditions: exact applied science; patient experimenting; a technical staff and its trained technical assistants, to be had at comparatively low salaries and wages; large-scale operations but not mass production.

Some bad things have been said of the tricks of the German dyestuffs producers and merchants, and of the unscrupulousness of their competition. Apparently much of this was true, but hardly more true than of the same industry elsewhere; the business seems to lend itself to the worst features of the competitive system. The United States had not failed before the war to develop some chemical industries without high protection, but these were of a different type from the higher grades of coal-tar products. Here as in other directions the successful American industries are those turning out great quantities of a single product by large-scale methods. My impression is that not lack of aptitude for chemical industries as such, not great scarcity of trained chemists or lack of ability on their part, but the character of the dyestuffs part of the industry mainly explains the pre-war situation. As a matter

of the international division of labor, the people of the United States probably would do well to turn to other things in which they work to better advantage, and get their dyestuffs from Germany. And—to go on with the purely economic aspects of the case—the war stoppage of supply raises the old question whether it is worth while to restrict the advantages of the international division of labor because of a possibility of its sudden disruption.

But quite a different phase of the war argument was urged in this case. The cool economic considerations, not of a sort to receive attention under any circumstances from the dominant party, were quite disregarded because of the stress laid on the chemical industries, and especially on the manufacture of coal-tar products, for the direct service of war. The same plant can be used for making dyestuffs and the like in time of peace, for explosives and for poison gas when war comes. The line of reasoning is similar to that applied in favor of subsidizing a merchant marine: the ships can be used for the ordinary purposes of transportation during peace and can serve as an auxiliary navy or transport system in time of war. The plea is more dramatically effective as regards the coal-tar products: be prepared to make your own explosives and poison gas! It was pushed to the hilt; and in this case once more the general protectionist atmosphere caused it to be welcomed, with little endeavor to ascertain just how far the military needs went, whether each and every kind of coal-tar product had to be bolstered up at home in order to meet these needs.

German Competition

On the other hand, domestic producers were so uncertain of their own position—so impossible was it to say just how much they had to fear from their dreaded German competitors—that they urged at first a complete prohibition, at least for a couple of years. In fact a virtual prohibition had existed since the close of the war through certain administrative regulations, and had been sanctioned by a temporary act of Congress. The proposal for the so-called embargo, however, proved unpopular, and though put in the bill as presented by the Ways and Means Committee to the House, was struck out by the House itself. After long debates in the Senate and with no little vacillation it finally was dropped from the act itself. In its place came some extremely high duties and some general administrative provisions which had no logical connection with the coal-tar products themselves but which nevertheless were expected or hoped to be applied to them.

The new rates of duty are extremely high. In 1916, when the war shortage of dyestuffs aroused attention, duties had been imposed upon dyestuffs of 30 per cent ad valorem plus 5 cents per pound. In the act of 1922 these rates become 40 per cent ad valorem (55 per cent until 1924) plus 7 cents per pound on the intermediate products and 45 per cent ad valorem (60 per cent until 1924) plus 7 cents per pound on the finished coal-tar dyes. The combination of specific and ad valorem duties is used, as it has been so often in the protective acts of recent years, to make sure that both the cheaper and the dearer forms shall be saddled with an effective high duty.

Much more important is the provision that these ad valorem rates shall be assessed, not under the ordinary procedure, but with "American valuation"; not on the basis of foreign market value, but on that of the selling price in the United States of a similar article of domestic production. Of the controversy that centered about American valuation in general more will be said presently. It suffices here to point out that the effective duty is made very much higher by its application and that this special treatment is made obligatory for the coal-tar products, and for them only. Alone in the act they are thus singled out. There are further provisions for the proper labeling and description of these articles, and (elsewhere in the act) for the application of special restrictions for the prevention of the "unfair competition"; provisions which are entirely proper and should serve to meet a real need of combating unscrupulous competition. The rates themselves, to repeat, are extremely high. Both the industrial and the military conditions are so extraordinarily complex as to render the problem quite the most difficult I have encountered in the whole history of tariff legislation. But it is certain that the military excitement caused the protective policy to be applied more rigorously than would have been the case if these two factors had not combined, and more so than is justified by either if taken by itself.

Electron Emission From Thoriated Filaments*

Thoriated tungsten filament is a tungsten filament containing 1 or 2 per cent of thorium, usually in the form of oxide. When such a filament is heated to about 3,500 deg. C., a little of the thorium oxide is changed into metallic thorium. In the meantime, however, any thorium on the surface of the filament evaporates off, leaving only pure tungsten. If the filament temperature is then lowered to about 1,800 deg. C., the thorium gradually wanders or diffuses through the filament, and when it reaches the surface, if the vacuum is very perfect, remains there and gradually forms a layer of thorium atoms which never exceeds a single atom in thickness. The thickness of this film is therefore about 1/100,000,000 of an inch, and yet this film increases the electron emission of the filament more than 100,000 fold.

Of course this film is very sensitive and needs some protection to keep it in good condition. Very slight traces of water vapor or other gases would oxidize and destroy it. This can be avoided by putting in the bulb some substance that will combine with the water before this has a chance to attack the thorium film. Such a substance is metallic magnesium. Furthermore, it is necessary to avoid heating the filament to too high a temperature, for otherwise the film might evaporate off. It is therefore best to operate such filament within a rather narrow range of temperature close to 1,700 deg. C., where the ratio of evaporation is very small and where the temperature is high enough for the thorium gradually to diffuse to the surface and continually repair any damage done by the effect of slight traces of residual gases.

The thoriated tungsten filament opens up many new fields of scientific investigation. By measuring the electron currents, it is possible to determine accurately exactly how much thorium is present on the surface. An amount of thorium corresponding to only 1/1000 of the surface covered with a layer one atom deep is easily measurable in this way. It is possible to knock off a thorium film by bombarding it with positive ions, moving at high velocities, and in this way the true nature of this bombardment can be determined.

The Magnetic Change A_2 In Silicon and Chromium Steels

It Is Impossible to Rely Upon the Loss of Magnetism to Indicate Proper Hardening Temperatures for These Steels, Since the Carbon Change Point Is at a Higher Temperature Than the Magnetic Change Point

BY HOWARD SCOTT
Associate Physicist, Bureau of Standards

IF A carbon steel is magnetized under high magnetizing force, a marked loss in its magnetism occurs on heating through the temperature where eutectoid cementite goes into solution (Ac_1). In consequence, that transformation of the carbide and iron can be readily detected by magnetic methods such as have been effectively employed in the investigations of Honda and his associates of the Japanese Iron and Steel Research Institute, and outlined in this periodical, March 30, 1921. Commercial advantage is also taken of this phenomenon in some forms of hardening equipment designed to indicate when the steel has reached a hardening temperature by noting its loss of magnetism. However, Ac_2, the magnetic change in the ferrite of certain alloy steels, occurs below Ac_1. The method noted is then inapplicable. Since two important alloying elements in sufficient percentages causes this inversion in the position of the critical points Ac_1 and Ac_2, it is intended to clarify the situation by presenting transformation temperature data on these alloy steels.

It was originally shown by Moore[1] that the magnetic change Ac_2 occurs below Ac_1, the carbon point, in certain chromium steels, while Charpy and Cornu-Thenard[2] found the same to be true for high-silicon steels. The phenomenon has escaped general recognition due to the peculiarities inherent to the method of thermal analysis commonly used in steel testing laboratories. On the differential or time-temperature curves ordinarily recorded, A_2 occurs as an indistinct bulge, lacking the easily recognized features it presents when the same data are plotted by the derived differential or inverse rate methods. To verify this, see the inverse rate heating curve for pure iron given at the left of Fig. 3. The fact is obvious enough when one considers that the inverse rate curves are of the same form as first derivatives of the differential curves.[4] Therefore, a peak or maximum in an inverse rate curve corresponds to a point of maximum slope on the differential curve and this relation must of course be observed if the results from data plotted by one method are to be made comparable with those of the other.

A_2 IN CARBON STEELS

The maximum rate of thermal change identified with the magnetic change A_2 occurs at the same temperature in pure iron and in low-carbon steels, both on heating and on cooling. That is to say, $A_2 = Ac_2 = Ar_2 = 768$ deg. C. When determined by suitable thermal methods,

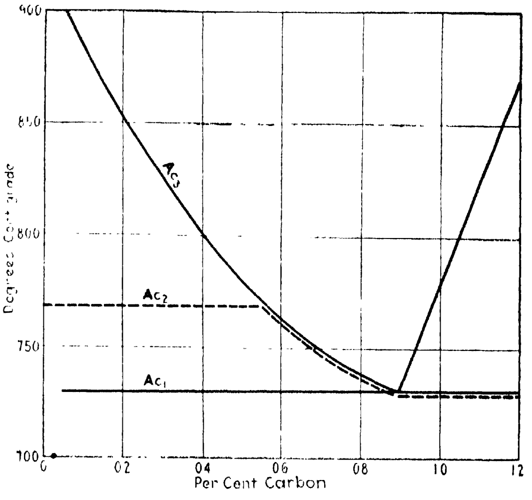

FIG. 1—THE TRANSFORMATIONS Ac_1, Ac_2 AND Ac_3 OF PLAIN CARBON STEELS

it is quite sharp.[5] The accompanying change of magnetization has, however, the peculiar property that it depends on the magnetizing force. With a low magnetizing force A_2 as determined by magnetic methods is very abrupt,[6] but when the magnetizing force is high and approaches saturation the steel begins to lose magnetism before reaching 600 deg. C., the loss continues with increasing rate upon further heating to 768 deg. C. and abruptly reaches a minimum just above this temperature. The temperature of the maximum rate of change of magnetism is, however, independent of the magnetizing force and corresponds to the temperature where the maximum amount of heat is evolved. Thus, notwithstanding the fact that loss of magnetism occurs over a considerable range of temperature, when suitable precautions are taken A_2 can be determined equally well by thermal or magnetic means, and the resulting data will agree.

Now when steels are heated, the pearlitic areas change into austenite at Ac_1. The ferrite plates which formerly existed in the pearlitic materials thus lose their identity, thereby losing whatever magnetism they possessed practically completely. But any excess ferrite left untransformed has the same unit magnetization as pure iron at the same temperature. The total magnetization remaining in low-carbon steels at any temperature between Ac_1 and Ac_2 is then roughly proportional to the amount of free ferrite present, providing the magnetizing force is high. (If the magnetizing force is low, only a very small part of the total change in magnetism occurs at A_1.) Thus, in

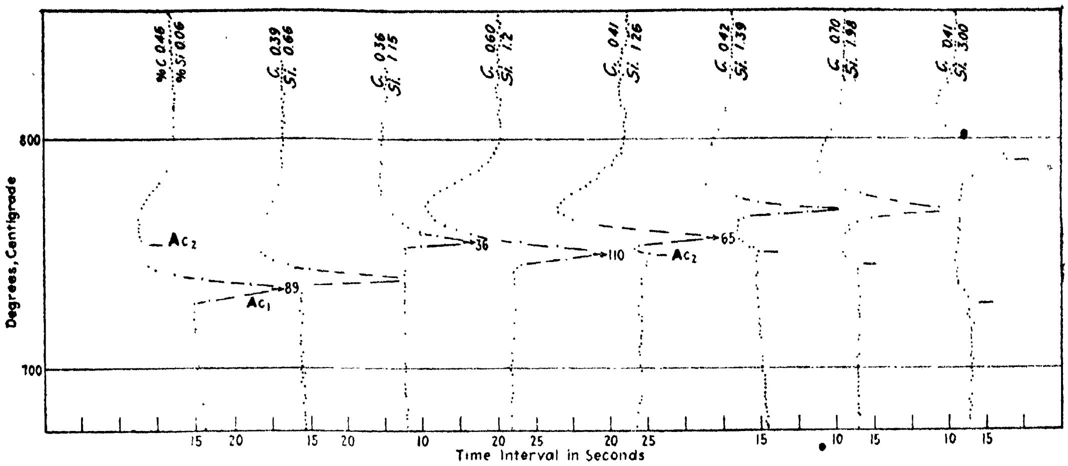

FIG. 2—INVERSE RATE HEATING CURVES OF SILICON STEELS

hypo-eutectoid steels the ferrite undissolved at Ac_1 gradually goes into the austenite solution as the temperature increases, so the total magnetization drops off from two causes—namely, the normal change of unit magnetization and the decrease in the amount of free ferrite through transformation to austenite. If carbon is so low that ferrite is not all dissolved when A_2 is reached, the remaining magnetism then disappears.

These facts regarding the temperature of disappearance of magnetism in steel are represented graphically by the broken line of Fig. 1, in which Ac_1 and Ac_3 are represented by solid lines. The horizontal for A_2 is deflected and continued just below Ac_3, from 0.55 per cent carbon, where it meets Ac_1, to 0.90 per cent carbon. For higher carbon contents Ac_2 is shown just below Ac_1, to indicate that the temperature of disappearance of magnetism actually coincides with the change of pearlite into austenite.

In Table I are given the significant data on silicon and chromium steels taken from inverse rate thermal curves obtained by the method described in Bureau of Standards Scientific Paper 348, and in the American Institute Mining and Metallurgical Engineers' Pyrometry Volume, page 2140. Heating curves for silicon steels are reproduced in Fig. 2 and of chromium steels in Fig. 3, together with comparison curves of a pure iron and a straight carbon steel.

Transformation temperatures are plotted against per cent alloy in Fig. 4 for silicon steels and in Fig. 5 for chromium steels. A_2 plotted in these figures for zero alloy is 768 deg. C., the same as in low-carbon steels. For compositions in which it occurs above Ac_1 the curve is broken; it is thus apparent that the magnet method for determining hardening heats is not directly applicable in silicon or chromium steels containing above 1 and 2½ per cent of alloy respectively.

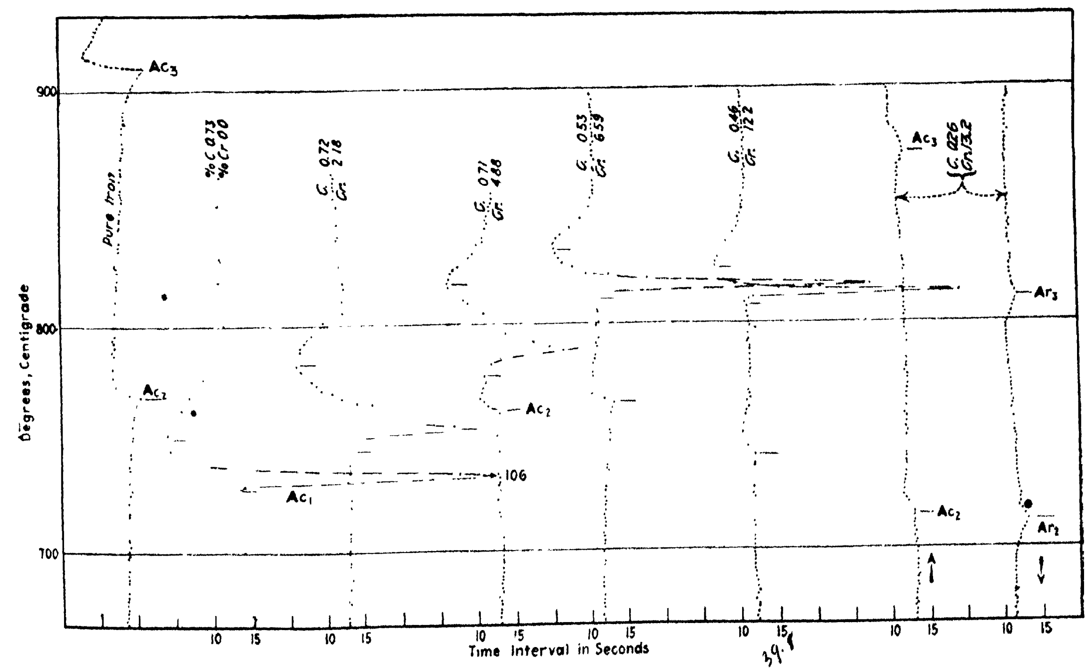

FIG. 3—INVERSE RATE HEATING CURVES OF CHROMIUM STEELS

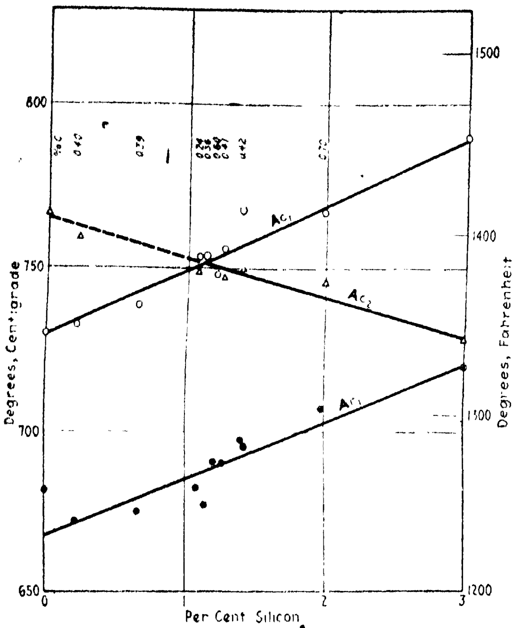

FIG. 4 THE EFFECT OF SILICON ON Ac_1, Ar_1, AND Ac_2 IN STEELS AVERAGING 0.45 PER CENT C AND 0.70 PER CENT Mn

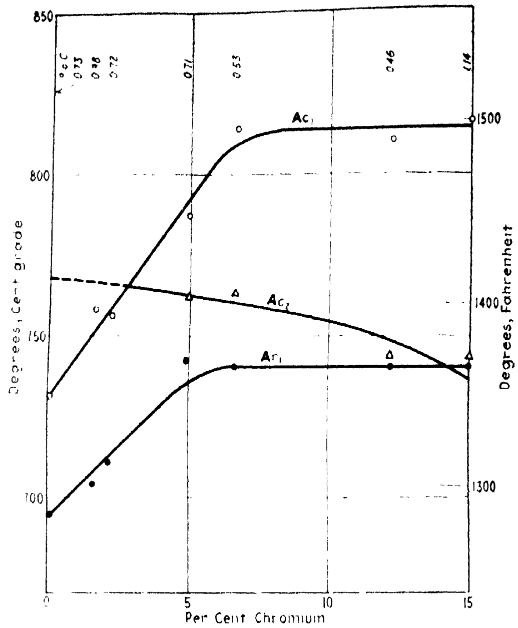

FIG. 5—THE EFFECT OF CHROMIUM ON Ac_1, Ar_1 AND Ac_2 IN STEELS AVERAGING 0.75 PER CENT C AND 0.45 PER CENT Mn

Values of Ac_1 and Ar_1 for zero silicon on Fig. 4 were obtained by interpolation of data on pure iron-carbon manganese alloys to correspond to an analysis of 0.45 per cent C and 0.70 per cent Mn, the average of these elements in the silicon steels. For zero chromium in Fig. 5 are used the values for a carbon steel of near the average carbon and manganese contents of the chromium steels, 0.75 per cent and 0.45 per cent respectively. Curves are drawn to represent the average carbon contents.

The principal effects of silicon are (1) to raise Ac_1 21 deg. C. and Ar_1 18 deg. C. for each per cent addition of silicon up to a content of at least 3 per cent; (2) to reduce the intensity and abruptness of these transformations; and (3) to lower Ac_2 at the rate of 21 deg. C. for each per cent silicon. Consequently Ac_1 and Ac_2 merge at 1.2 per cent silicon, and if the curves be extended above 3 per cent, A_2 would also cross Ar_1. A_2 is lowered at the same rate in pure iron-silicon alloys, according to the magnetic observations of Murakami,[1] until 450 deg. C. is reached for a 17 per cent silicon alloy, the limit of solid solubility, at which temperature it remains for higher silicon contents.

Since there is such close agreement between commercial alloy steels and pure Fe:Si alloys, A_2 is not affected by carbon in the form of cementite in silicon steels (as is equally true in plain carbon steels). These facts do not mean that dissolved carbon has no influence upon A_2 unless thereis a change of solubility at A_2. Moore[2] proves there is not. We know that carbon content has little effect on Ac_2, so these curves of Fig. 4 are probably reliable for the range of carbon contents found in commercial steels.

Data on chromium steels are rather limited, but show clearly the effect of that element in reversing the ordinary relationship of Ac_1 and Ac_2. Chromium does not affect Ac_2 markedly except in the higher alloys, but Ac_1 is raised rapidly up to about 810 deg. C. at 7 per cent chromium, after which the concentration-temperature curve flattens out. Ar_1 is raised in the same manner, but not as rapidly; therefore the lag between transformation A_1 on heating and cooling increases

with the chromium content up to 7 per cent. The rate at which Ac_1 rises is about half as fast as in the silicon steels, and Ac_2 crosses Ac_1 at 2.5 per cent chromium.

Edwards, Sutton and Oishi[8] have determined the critical ranges of a very complete series of chromium steels, but their values are considerably higher than those given here for equivalent steels. This discrepancy is probably a result of their method of recording data taken from the differential curves. The values for steels within their series are, however, comparable and show that Ac_1 is not affected appreciably by considerable differences in carbon content. The same is true of the observations noted by Russell[4] and of those presented here for carbon contents above about 0.40 per cent. When lower carbon-chromium steels are studied another factor apparently enters.

Data given in Table I for two steels of less than 0.40 per cent C and containing 13.2 and 15.8 per cent chromium respectively show that the upper transformations of these steels occur at a much higher temperature than in similar steels of slightly higher carbon content. The last two curves shown in Fig. 4 are heating and cooling curves of one of these steels. The high temperature, the marked dimunition of intensity and the change in shape of the inflections indicate that the transformation involved is A_3 rather than A_1. This suggests that carbon up to about 0.40 per cent is soluble in ferrite containing high chromium, but there are insufficient data available to verify this. It is, however, significant that Monypenny[9] finds the solubility of carbon in austenite to be greatly decreased by chromium. In consequence, chromium steels containing over about 0.40 per cent carbon and 12 per cent chromium are hypereutectoid, and A_1 only is observed on thermal analysis.

SUMMARY

From a discussion of thermal and magnetization curves, it is noted that $A_2 = Ac_2 = Ar_2$ is a continuous change in the magnetization of ferrite reaching a maximum rate of change at 768 deg. C., just below the temperature of total disappearance of magnetism. In carbon steels this change differs from that in pure iron in degree only, a circumstance which is caused by the transformation of ferrite to austenite within its range.

The critical temperatures Ac_1, Ar_1, and Ac_2 are modified in the following manner:

Ac_1 is raised 21 deg. C. and Ar_1 is raised 18 deg. C. for each per cent silicon added up to at least 3 per cent, while Ac_2 is lowered 21 deg. C. for the same increment.

Chromium raises Ac_1 11 deg. C. and Ar_1 6 deg. C. for each per cent addition up to about 7 per cent, above which they are stationary, but it lowers Ac_2 only in the higher percentages.

Chromium steels containing in excess of 0.40 per cent carbon and 12 per cent chromium are hypereutectoid.

Ac_2 occurs below Ac_1 for silicon contents above 1.2 per cent and chromium contents above 2.5 per cent.

When Ac_2 occurs below Ac_1, the latter change is not detectible by the usual magnetic methods and so equipment depending on the loss of magnetism for indicating the proper hardening temperature cannot function for high silicon and chromium steels.

Recent Experiments on Chlorine Volatilization

Experiments were made at Bureau of Mines station, Salt Lake City, Utah, on some lead-zinc concentrates for the Kirk-Simon Smelting Co., Harbor City, Calif., in an endeavor to make a separation of lead and zinc. The procedure consists of separating part of the lead as the oxide and part as chloride by the addition of salt, and then a reducing agent was added to make a good grade of zinc oxide from the zinc residue.

Following some volatilization experiments carried on in co-operation with the Chief Consolidated Mining Co., Eureka, Utah, this company erected a semi-commercial plant which includes horizontal Cottrell treaters and a three-compartment bag-house. It was found that treatment of pulped fume with milk of lime would make an acceptable product, containing the values in a concentrated form, and could be sold to the smelters. Experiments made on the electrolytic treatment of fume in a fused bath showed excellent recoveries of the silver, with a good current efficiency.

RECOVERY OF SILVER, LEAD AND COPPER

A good deal of work has been done to determine why it was more difficult to volatilize silver than lead when the two were present in the same ore. It was found that silver chloride formed readily and was quite stable under furnace conditions, but that it required considerable time at high temperature to volatilize even after it was formed. Aeration of the charge reduces this time materially. Vapor pressure of $AgCl$ is low at 1,000 deg.

After testing a variety of ores and looking over former work it seems that the best field for the immediate utilization of the volatilization process lies in lead-zinc separation. It was also found that most of the lead could be separated from the zinc as lead oxide, and many fields for oxide volatilization are now being opened. A good zinc concentrate can be made from many ores which are at the present time too high in lead to have much commercial value, and at the same time the sulphur can be eliminated to save freight.

CHEMISTRY OF THE VOLATILIZATION PROCESS

During the past fiscal year an effort was made by the Bureau of Mines to get some valid fundamental data upon which might be based the chloride volatilization work. Up to this time this work has been divided into four principal divisions: (*a*) A study of the effect of elemental chloride on a zinc carbonate ore. (*b*) Various theoretical calculations of vapor pressure, heats and reactions, and various predictions as to courses of reactions and applicability of various metallic chlorides as chloridizing agents. (*c*) Direct measurement, by a static method, of the vapor pressure of various metallic chlorides. (*d*) The measurement of equilibria in systems consisting of a metallic oxide, metallic chloride, oxygen and chlorine.

Zinc Condensers

In large-scale experiments with the distillation of zinc by the electric current, difficulty has been encountered in the fact that condenser linings made from ordinary refractories break down due to carbon deposition around particles of iron oxide contained in the refractory material. Small-scale experiments are being carried on at the Rolla station of the Bureau of Mines using condensers lined with various iron-free refractories to determine what materials are permissible for this purpose.

Pyrex Glass as a Material for Chemical Plant Construction*

Boro-Silicate Glass Has Already Established a Unique Place for Itself in Chemical Industries and the Possibilities Are Tremendous—Less Than a Year Ago Industrial Pyrex Was Undertaken Seriously—The Progress Made Is Reported in This Paper

By A. E. Marshall
Consulting Chemical Engineer, Baltimore, Md.

Anyone who has undertaken construction work on chemical plants, whether for the manufacture of mineral acids or less corrosive products, will admit that no available material gives satisfactory service under all conditions.

Materials in general use have specific advantages for specific work, and the chemical engineer utilizes a number of different materials in one piece of construction in order to develop maximum durability under varying conditions. Incidentally, durability is in many cases synonymous with resistance to corrosion.

Glass, because of its insolubility in acids, has always found uses in the chemical industry, but its limitations in the way of temperature resistance have restricted the field of application.

Limited Use of Ordinary Glass in Industry

Ordinary glass, if desired to withstand moderate temperature changes, has to be made into shapes with thin walls, and such shapes when thin enough to survive slight heat shocks are much too thin to stand up under ordinary plant usage, or in many cases to survive rough handling during erection.

The desire to make use of the non-corrosive properties of glass has led to its being tried out under a variety of plant operating conditions, but the inherent disadvantages of ordinary glasses so far outweigh the useful features that it is difficult to point to successful applications in plant-scale work except under special circumstances.

I remember making a survey some years ago of materials used in the construction of gas-conveying lines from hydrochloric acid pots and muffles. One plant at the time of my visit was using 15-in. slip joint glass pipes on the pot line. Very good results were being obtained because of the thorough cooling of the gas in its passage through the thin-walled pipes to the absorption tower. Later inquiries indicated rather heavy breakage during the winter months, the cause being ascribed to leakage of melted snow through the roof and onto the pipes, or to the considerable difference in temperature between the atmosphere and the gas inside the pipes.

There was a purely local reason for the use of glass on this line. The chemical plant adjoined a glass factory, and the glass pipes were thin cylinders from the plate glass department.

When wire glass was introduced it seemed to offer decided possibilities to the chemical industry, and it was tried out for various uses without any great measure of success. I was very much interested in sulphuric acid concentrators at that time, and I substituted some wire glass plates for the acid-proof cover slabs on a cascade concentrator. The glass cracked in the course of a few hours and thereafter final collapse was merely dependent on the time required for the acid fume to attack the wire reinforcement.

Other engineers have endeavored to utilize glass in various ways, and where temperature resistance and mechanical strength have not been essential, the material has proved satisfactory. I have in mind, as an instance, the glass-packed Gay-Lussac and absorption towers introduced in England about 1909 by Carmicheal. These towers, usually of square section, are packed with annealed plate glass sheets, set on edge and spaced fairly closely. Each successive layer of packing is placed at right angles to the row below, thus giving excellent surface contact and good gas distribution.

Mention has been made of attempts to use, and the actual use of, ordinary glass in plant construction, because such attempts afford evidence of a desire on the part of the chemical industry to utilize the valuable non-corrosive properties of glass.

Industrial Possibilities of Pyrex Realized in Laboratory Ware

With the introduction of Pyrex as a laboratory material and as a domestic utility in the form of baking ware, the possibilities of using glass in plant construction assumed a more promising outlook. Chemical manufacturers tried out Pyrex baking ware for small-scale chemical operations, drawn Pyrex tubes were used in Hart nitric acid condensers, and many other minor uses were discovered for the standard shapes which were being produced for the laboratory or the home.

In December of last year the author suggested to the Corning Glass Works the desirability of gathering together these sporadic developments and investigating the possibilities of producing a line of Pyrex products designed for the use of the chemical industry. The field appeared promising, and a decision was reached to establish an industrial Pyrex department, the author being retained as consulting engineer.

Before entering into a description of the present state of development, it is necessary to set forth the essential characteristics of Pyrex and the difference in its properties and ordinary glass.

What Pyrex Is

Pyrex is a low-expansion boro-silicate glass of simple chemical composition, containing no metals of the magnesia-lime-zinc group and no heavy metals.

A comparison of the linear expansion coefficients of Pyrex and a number of materials is given in Table I and, as will be seen, Pyrex has a smaller coefficient than porcelain, ordinary glass or any of the usual metals.

The low coefficient of expansion introduces a marked distinction from ordinary glass whether of the lead or lime-soda type.

Soft glass	0.0000085
Cast iron	0.0000102
Wrought iron	0.0000119
Portland cement	0.0000120
Copper	0.0000167
Brass (66Cu-34Zn)	0.0000190
Zinc	0.0000258
Lead	0.0000276

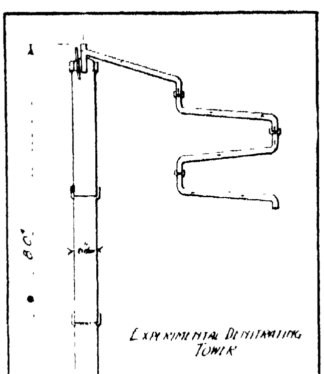
The melting point of glass is not particularly valuable as an engineering consideration, as there is usually a fairly wide range between the initial softening point and final melting point. In the case of Pyrex, the softening point is about 800 deg. C., but the material will soften slightly, especially under pressure, if maintained for a long time above 600 deg. C.

In connection with the softening point it is useful to remember that devitrification, which is a serious factor in the use of some materials, does not affect Pyrex in its working range.

Comparative Acid Resistance of Glasses

Acid resistance is not usually given much thought in the case of glass, the general assumption being that all glasses are equally resistant. Bulletin 107 of the Bureau of Standards gives considerable data on the acid-resisting qualities of Pyrex and other glasses, and is well worth study. Researches have also been conducted in the Corning laboratories on the resistance of Pyrex to perchloric, phosphoric, constant boiling hydrochloric and concentrated sulphuric acids under a variety of conditions.

The action of hydrochloric and sulphuric acid is very slight, constant boiling hydrochloric acid attacking Pyrex at a rate of 0.000006 gram per square centimeter per hour. Concentrated sulphuric acid in 4 hours at the fuming temperature shows an attack of 0.000002 gram per square centimeter per hour. Both figures relate to initial surface attack, as after the lapse of a few hours a state of practical stability is reached.



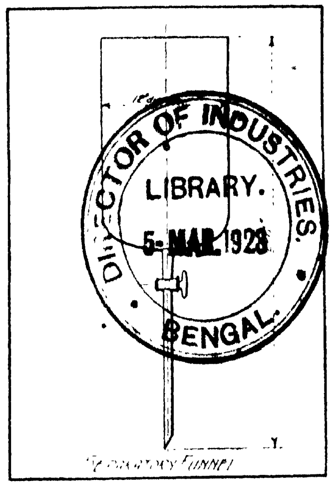
INSTALLED BY THE DU PONT CO.

Work on the coefficient of heat transference is being carried out at Corning, but has not been completed. Preliminary results on the relative efficiencies of Pyrex, porcelain and stoneware indicate Pyrex and porcelain as equal, whereas stoneware shows about one-half the Pyrex value.

It can be said that while Pyrex is superficially a glass, its physical characteristics justify consideration from the engineering standpoint as a special and distinct material adapted to a variety of industrial uses to which ordinary glass cannot be applied.

The Development of Industrial Shapes

Proceeding from a consideration of useful properties to the development of definite industrial shapes, it is obvious that the upper limit of size is a factor of great importance. If the sizes had to be restricted below the usual standards in other materials, then the field of application would also be restricted. It was not practicable to pick out very large pieces and concentrate on them, for the reason that failure in manufacture might be caused by lack of dexterity in handling such large shapes. The history of most plant materials, stoneware, fused silica, high-silicon irons, etc., has been one of gradual enlargement of product. In the case of Pyrex the existing laboratory and domestic shapes could be used as a starting point and a stage selected which would represent useful commercial products without going out to sizes which would call for the introduction of new methods of handling.



ONE OF THE FIRST PIECES OF PYREX INDUSTRIAL EQUIPMENT

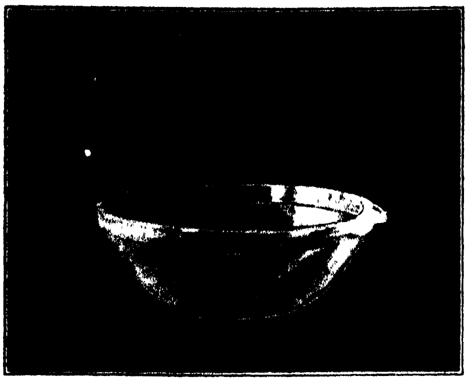
The starting points selected were therefore an 18-in. evaporating dish, a 6-in. bore socket pipe 39 in. over all, and a cylindrical pot 12 in. in diameter by 20 in. high.

It was expected that difficulties would develop in the manufacturing process; but contrary to expectations, production was worked out with nothing more than the usual minor troubles.

With proof that manufacture was possible, it was then necessary to test out the product under working conditions. These tests were made on single pieces in various plants, and following satisfactory reports, distribution was started on a small scale.

The application of these first available shapes brought along a demand for other forms of Pyrex equipment, and as a consequence new items have been added in the last few months, while others are approaching the production stage.

Reference is directed to the 72-liter capacity retorts, designed for distillation and reaction work, various



PYREX DISH, 25 IN DIAMETER AND 30 LITERS CAPACITY

sizes of pots up to 9-gal. capacity, and large separatory funnels of 8-gal. capacity as articles now available.

Pyrex glass is also being produced in sheets 14x18 in., and it is expected that much larger sheets can be made if there is the necessary demand

In addition to the above items a 25 in diameter dish of 30-liter capacity is about ready for distribution. 12-in. socket pipes will follow in a few weeks, and other shapes of equivalent size, such as a drier tray, cascade dishes, etc., will be put in production as soon as a demand is assured.

Incidentally the use of Pyrex in forms developed especially for the chemical industry has created interest in the possibilities of equipment made from Pyrex tubing. Condensing equipment made up of "S" bends, pipe lines with socket or butt joints, and many similar uses are becoming standardized.

A Pyrex Denitrating Tower

An interesting piece of Pyrex equipment was constructed recently for the du Pont company. This was in the form of an experimental denitrating tower 6 in. in diameter by 8 ft. high. All parts, including distributor, inlet and outlet connections, were Pyrex. It is understood that the tower has given satisfactory service, despite rather strenuous conditions

The use of Pyrex in actual plant work has developed some interesting sidelights, not only on applications but on a phase of excessive cost, created by a lack of standardization. This point will be discussed later.

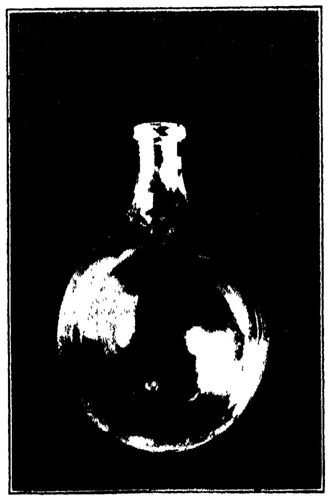
It had been expected by users that there would be a higher handling breakage with Pyrex dishes than with porcelain. Experience has been entirely to the contrary, and the reason apparently lies in the province of psychology. One plant, which is now completely equipped with Pyrex dishes, reports handling breakages as nil, and states that the men treat the dishes as glass, setting them down with care and so obviating breakages through dropping. It has been the experience of every user of Pyrex, irrespective of the shape of the article, that transparency creates care in handling. It is a natural assumption that an opaque object will withstand shocks and that a transparent one will not, so a transparent material which is at least equal to stoneware and porcelain in mechanical strength has a much better chance to survive at the hands of a workman. Transparency has other advantages which are not psychological. The first and most important is that a transparent article cannot have blowholes or other hidden flaws. Even strains can be detected by the use of a special polariscope, this being one of the routine tests to which every piece of Pyrex equipment is subjected in the Corning factory.

Next comes the question of cleanliness. Opaque equipment may or may not be clean, but transparent equipment always supplies its own positive answer on this point. Finally there is the feature of controlling reactions through direct observation.

Advantage of Rapid Process of Fabrication

Another interesting feature which has been brought forward by users is in relation to the process of manufacture. Pyrex is to a certain extent competitive with chemical stoneware. The process of making stoneware is quite lengthy, the time required being about 2 months. Breakage of a special piece of stoneware, provided there is no duplicate in the plant store room or at the stoneware manufacturer's works, means a long delay in starting up after the shut-down. Providing a mold exists for the piece in Pyrex, manufacture can be completed in 3 days as a minimum, although factory conditions might necessitate a delay of a few additional days on account of prior routing of work.

Touching on the phase of excess costs of construction materials, it seems very desirable to emphasize the lack of standardization in the chemical industry. Molds are costly, whether they are intended for stoneware, silica, Pyrex or other materials. The manufacturer of the equipment has to charge up his mold cost to the



A 72-LITER RETORT

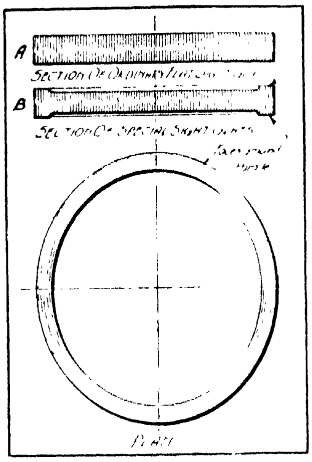
user, and there seems to be too great a demand for "specials"—which may vary only ⅛ in. from a stock mold. Some concerted effort to standardize shapes would cheapen the products, and, of equal importance, would enable producers to carry representative stocks. A striking example of the lack of standardization is shown by the Corning Glass Works list of sight glass molds. Continuous efforts have been made to keep down the number of sizes, but the success can be judged when it is shown that between the range of 2½ in. diameter by ¼ in. thickness to 8½x¾ in. it has been necessary to provide forty-one molds.

In the case of plant equipment, a further effort is being made to work out shapes which will suit a variety of uses, and it is hoped that a full measure of cooperation will be extended by plant managers and engineers, through the use of stock rather than special molds.

The industrial use of Pyrex is spreading into many fields, and while not a strictly chemical application, decided interest attaches to the development by the research laboratories of the Corning Glass Works of Pyrex high-tension insulators.

The generally accepted causes of failure of porcelain high-tension insulators are: (1) change in structure of porcelain with time and absorption of moisture; (2) breakage due to thermal changes; (3) flaws in the porcelain body, causing dielectric and other failures; (4) failure due to expansion of cements used in attaching hardware to the insulator; (5) mechanical weakness. These failures may be generally classified as failure due to the properties of the insulator and failure due to design.

Pyrex glass seems to have ideal properties for an insulator, for it apparently is not subject to any of the intrinsic weaknesses of the porcelain insulator. It does not change in structure, can be inspected for any defects, thus assuring a uniform product, has a sufficiently high dielectric strength, a great resistance to thermal changes (its thermal expansion coefficient being lower than that of porcelain) and in addition is not heated by direct solar radiation as much as porcelain. Consequently if a Pyrex glass insulator could be built free from the design defects of the porcelain, there is no question that it would be a better insulator.



SUGGESTED DESIGN OF PYREX SIGHT GLASS

Fig. 1 shows the construction of the Pyrex insulator. It is evident at a glance that this construction and design gives a cement-free, all-metal and glass insulator and that the design is one of great resistance to tension, as the material of the insulator is largely under compression.

Considerable data have been collected showing the relative properties of Pyrex.

Heating of glass and porcelain insulators by solar radiation shows a rise in temperature above air temperature for a porcelain insulator of 39.5 deg. C., and for a Pyrex insulator of 10.8 deg. C. This is a mean of ten observations in both cases. These data show the increase in temperature due to solar radiation to be 3.65 times as much for the porcelain as it is for the glass. **The glass is transparent and the porcelain absorbs the heat radiation. This proves that in service the glass is not subjected to anything like as severe heat changes as porcelain.**

In a report on dielectric strength tests made by one of the large manufacturers of electrical equipment it was stated that unit No. 1 punctured at 143 kilovolts, unit No. 2 punctured at 160 kilovolts, and unit No. 3 punctured at 140 kilovolts.

"The tests on Pyrex suspension insulators show quite conclusively that the material has good characteristics. The uniformity of electrical puncture is a distinct advantage over porcelain."

It is evident that Pyrex glass has very good dielectric properties, more than ample for the service, as well as being uniform.

Tensile strength tests made by Cornell University, Sibley College, show:

No. 1.	22,600 lb.	No break
No. 2.	23,000 lb.	Pin broke in holding device
No. 3.	19,500 lb.,	Pin broke in holding device, reaction broke insulator
No. 4.	22,750 lb.	Yielding, no break
No. 5.	23,600 lb.	Cracked
No. 6.	20,600 lb.	Click, no break
No. 7.	21,800 lb.	Click, cracked
No. 8.	22,000 lb.	No break
No. 9.	17,000 lb.	Click
	22,500 lb.	Click again, cracked
No. 10.	25,460 lb.,	Broke stud, flange shattered by reaction, head O. K.

Since the better grades of porcelain insulators will not stand over 10,000 lb. load as a maximum, and many break below that, it is evident that the glass insulator has a strength far superior to anything yet developed. This property should allow for longer spans, and in many cases where two strings of porcelain are used in parallel one of Pyrex will be ample to carry the load.

Pyrex glass has a great resistance to water absorption and surface attack, and is therefore durable under long exposures to severe atmospheric conditions, as for instance around chemical plants.

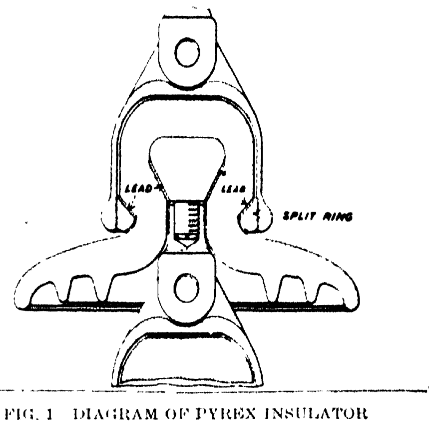


FIG. 1 DIAGRAM OF PYREX INSULATOR

It is probable that glass insulators will not be as attractive to birds and spiders for nesting sites, since they will not have the dark shadows that exist in a string of porcelain insulators.

The chief advantages of the Pyrex insulator are the fact that it does not absorb heat as does porcelain; has no cement in its construction gradually to absorb water and expand, ultimately fracturing the insulator; and has a mechanical strength that will average twice as high as any porcelain insulator yet on the market.

This paper describes in sufficient detail the present status of industrial Pyrex, and carries a suggestion of future possibilities. It is believed that Pyrex will in a short time occupy a definite place along with the other materials used for plant construction. It is not a universal panacea for construction ills, but, like everything else in our practice, it demands thought in its application and care in its use.

European Conditions as I Saw Them*

Deplorable Policy of Feeding the German Masses With Propaganda of Hatred Toward Former Enemies, Particularly the French—Salvation of Germany Depends on Payment of Honest Wages and Sale of German Products at Prices Commensurate With Their Intrinsic Value

By J. S. Negru

As I now pass in review my impressions gained in Germany during my visit there during the summer of 1922, I am compelled to say that the worst which has befallen the German people is not the loss of the war, but the policy of a handful of Germans who keep the remainder of their countrymen practically in complete ignorance of what the outside world has learned about Germany's doings during and after the war.

Although throughout the war, the Germans employed means which alienated for them the consideration which is due to a civilized people, even to this day they know only about their own sufferings and privations, and seem not to have the least idea or thought of what was and is going on elsewhere. Since the war they have been led to believe that the conditions which have been imposed upon them were not imposed as a means to alleviate conditions caused by their acts during the war, but as a concerted plan to destroy them as a people.

For this state of mind, a handful of Germans is responsible. They are the leading industrials of the country, who grew immensely rich during the war, and after the war dreamed of mastering the world's markets. This they have done by feeding the people systematically with hatred propaganda, at the same time compelling them to work for ridiculously low prices and selling for export German products requiring large amounts of manual labor at far below their real value. This procedure did not have the effect which the industrialists expected. Instead, it has resulted in Germany gradually falling in the estimation of other nations, and has created a feeling of distrust which it may take her generations to live down, and thus regain her lost place in the community of nations.

While I was in Germany I stated openly my impressions, as I received them, to practically all Germans with whom I came in contact, hoping by this means, if I were mistaken, to compel them to tell me facts which might lead to nullifying or modifying those impressions. Therefore, the judgment at which I arrived as to actual conditions in Germany is free from any personal bias.

Pride in Germany Before the War

Germany before the war was strong and boastfully conscious of her strength. There was then no visible hatred toward any foreign nation, foreigners were treated with the consideration due to visitors. Her cities were well patrolled and everything was minutely regulated according to the "verboten" dogmas. Her railways were considered the best in the world as to regularity of traffic. She pointed to her intellectuals with almost as much pride as she did to her uniformed defenders of the Vaterland. The results of her researches were made public freely and served as steps in the advancement of human knowledge. Her scientific and technical magazines and books were standard, sought for and studied by all who wished to attain recognition as savants. The degree of Doctor obtained in German schools and German universities was the open sesame to the fraternity of the learned. The German students were the coming leaders and were aware of their importance. Her factories were busy and the workmen imbued with the spirit of the then real meaning of the label "Made in Germany," which was the production of goods which competed honestly as to quality and price with those of other industrial countries. Her workmen were contented and received what was considered a fair return for their labor. Business ethics were summarized in the term "Ein Mann ein Wort" (a man's word). In brief, Germany was a great country, but even then she was suffering from an illness which accompanies the exalted belief in self-importance—namely, she was conceited and became so to such an extent as finally to consider herself as the anointed for dispensing to the rest of the world the blessings of Kultur.

The Germany of today is sick with the sickness of hatred. Economic war, wailing notes, conferences, blaming others are like patent medicines; the medicine Germany needs is just plain honesty toward herself and others.

Hate, far more than anything else, is now corroding

DISTINGUO ALLEMAND

— Après Petersdorf Hamborn, après Hamborn Gleiwitz! Il faut que cela cesse..
— Mais, Mylord, pourquoi vous fâcheriez-vous? Il n'y a jamais d'Anglais « accidenté »,

*This is the seventh of a series of articles by Mr. Negru on this subject. The preceding articles appeared in the issues of Oct. 18, Oct. 25, Nov. 8, Nov. 15, Nov. 22 and Nov. 29. This article was written in September, 1922.

the German people. They have made out of it a new religion, "Hatredism," if I may use this expression, which they worship with fervor. France conveniently personifies the mortal enemy of their good god Kultur, hence it is on France that all Germany's imprecations are heaped. The leaders in Germany well know that others, in particular England, were and are just as mortal enemies of their type of Kultur, but it would not do to use them all at the same time, as the masses of worshippers might then be confused as to which was which; hence the superficial tolerance for the non-French.

The accompanying cartoon "German Distinction," by Louis Raemaekers, taken from the April 16, 1922, issue of *Le Soir*, Brussels, illustrates better than words could do the idea which the Germans have of tolerance. The caption reads:

ENGLAND — After Petersdorf Hamborn, after Hamborn Gleiwitz! This must stop.

GERMANY — But, my lord, why are you offended? There are never any English casualties.

This refers to the occurrence when French soldiers were killed and wounded by the explosion of concealed ammunition.

Hatred of French Is Bred Systematically

The Germans have a league for the protection of the German Kultur (Liga zum Schutze der deutschen Kultur). I had heard something about the activities of this league and of its itinerant exhibition, giving a series of graphical and statistical descriptions of what the peace treaty meant to Germany. I had an opportunity to visit this exhibition in Berlin, which was the forty-second city in which it was held since it was conceived.

If ever there was an efficient means of arousing fanatic hatred, this kind of exhibition can surely claim first prize. It was unilateral and partisan, showing effects only and absolutely no trace of causes. The walls of the halls were covered with a series of tables, twenty-eight of them the subject of Wilson's fourteen points, the others dealing with Germany's lost colonies, lost German territory, loss of minerals and agriculture, payment for reparations and so on. In the main hall, a raving anti-French denunciator and agitator was addressing the audience, which looked like a congregation of raptured fanatics.

The masterful poster for this exhibition is here reproduced. Can there be any more suggestive picture resembling a huge antediluvian animal with a heavy body and a diminutive head? It is entitled "The Chained Germany."

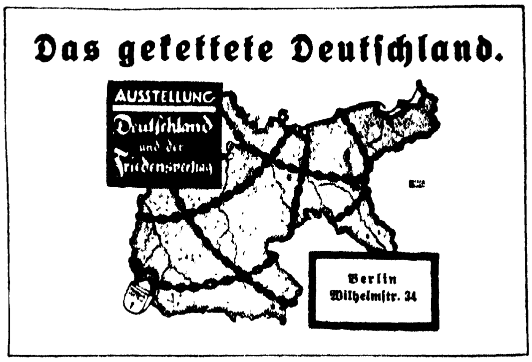
I am a believer in free speech, free press and the like. I have nothing to say against the exhibition, the speaker, and the audience. The exhibition is a business proposition, the speaker surely a hireling and the audience consisted of grown-ups, so all was what might be expected in any constitutional country.

But where I am compelled to draw the line is that in the morning preceding the day on which I visited the exhibition I saw a large group of girls about 14 years of age, accompanied by their teachers, waiting on the street and in the yard of 34 Wilhelmstrasse for the doors to open. I learned afterward that the forenoons were reserved for school children and their teachers. It is criminal to poison the minds of children with such exhibitions as these, especially when the parents of these children are exploited to the extent that they receive only the very minimum-for-existence wages, at the time of which I write on the average of about $2 per week. Would it not be far healthier for all concerned that instead of such exhibitions there should be in the German press honest accounts as to what really becomes of German work? Also, why it is possible that a workman receives only about $2 per week, when the intrinsic value of the product of his work is even more than before the war, when he received at least $6 per week. This is the condition which is the very cause of Germany's present plight.

Meeting a Locksmith in the Tiergarten

This steady feeding of hate, which is so very conspicuous in every place which I visited in Germany, has embittered even the minds of their scientists. During a conversation with B., a leader in metallography, he used a language of hatred strikingly similar to that which I heard from S., a plain locksmith in a tent in the Berlin Tiergarten.

The meeting with B. was at my request, but that with S. was accidental and deserves to be related more in detail. It was on a Sunday afternoon. After a long promenade in the Tiergarten, I entered a tent show, paid the entrance fee, 6.20 marks (about 2 cents), sat down at a table and ordered black coffee. A few moments later a couple took their places at the same table, and also ordered coffee. When this was brought, the man



looked in disgust at the small pots of coffee and cups the size of demi-demi-tasse, if I may use that expression. He evidently expected to receive the large cups of coffee that I well remember in such places in the years gone by, especially since while waiting for the coffee the couple had taken out the sandwiches which they had brought with them for their lunch. When he learned that the price was 12 marks (about 4 cents) per pot, he started to argue with the waiter that it was too dear, and on learning that the price of beer was 7 marks, ordered the waiter to take the coffee back and bring them two glasses of beer instead.

This gave me opportunity to start a conversation which lasted about two hours and a half. I learned that he was a locksmith, earning 600 marks a week (about $2). The entrance fee to the tent (6.20 marks each for himself and wife) plus the 12 marks for coffee, making a total of, say, 11 cents, was too much for them, as with this sum they could have purchased meat and bread for a good dinner. It furnished the pretext for a series of imprecations against the French and why an honest German workingman cannot afford even once in a while an enjoyable outing on a May day Sunday afternoon. The burden of his song was that the French

are the masters of Germany and squeeze out of her every drop of the proceeds of her work, etc. Needless to say, he believed that it was so.

Cannot the German intellectuals see that the ever-exaggerated accusations against the French and others are driving the German masses to the fixed idea of a savage crazed with hatred? Can they not think of what might happen if these men were at last to learn that their work has served in reality to enrich a few Germans and to alienate the good will of the rest of the world, because of the very abnormal low selling prices of the products of their work?

It will not be long before the German masses will learn that huge sums are being placed by German industrials in foreign countries and that the payments already made for reparations are a small proportion only of the German annual productive wealth.

I may cite here the following which was printed in *Le Matin* of Paris, under the heading "Stinnes offers to Jugoslavia a Loan of $100,000,000:"

> Belgrad, 8 May, 1922—*Novosti* of Belgrad, the governmental organ, announces that a financial consortium, behind which is the famous Hugo Stinnes, has lately offered to the Jugoslavian Government a loan of $100,000,000 for the construction of new railways from the interior of the country to the Adriatic ports.

What Germany needs now more than ever is not to hear hate, read hate and think hate, but to have her workingmen get wages commensurate with the true value of their work and sell her products at honest prices.

Other articles by Mr. Negru on this subject will be published in subsequent issues.

Legal Notes

BY WELLINGTON GUSTIN

Where Combination of Old Elements Is Patentable

The Circuit Court of Appeals of the United States at St. Louis has affirmed the judgment of the District Court in a suit brought by the Laclede Christy Clay Products Co. against the City of St. Louis and has denied a rehearing on the matter. (280 Federal, 93.)

SUSPENDED ARCH CONSTRUCTION ANTICIPATED

Suit was brought by the Laclede Christy Clay Products Co. against the city for infringement of a patent, known as the Girtamer patent, No. 986,455, claims 1 to 3. This patent covers claims for a furnace arch having parallel I-beams on which are brackets from which tile are suspended by a tongue and groove arrangement. The court found there was not only anticipation by prior patent issued to Stimmel, No. 944 296, and to Green and Gent, No. 676,606, and to Poppenhusen, No. 783,132, in the use of more than one transverse support; but also the question whether two (or more) I-beams (or girders of other form) should be used as called for in the three patents rather than one as called for in Girtamer's first patent, No. 910,809, was a question answered by mechanical suggestion when it is desired to make the arch longer. Again, the court said there was nothing new in the patent in suit, for Girtamer's first patent has the grooved tile fitting into lateral extensions of pendent portions of the brackets. Even this point is identical with Green and Gent's patent.

USE OF SEVERAL PARTS INSTEAD OF ONE TO PRODUCE SAME RESULT NOT INVENTION

It was contended that Girtamer's first patent called for one transverse I-beam which supported integral brackets extending rearward and forward over the length of the arch, while the structure disclosed in his second patent, which calls for two I-beams spaced apart, with brackets in three separate pieces, one extending forward from the front I-beam, one extending rearward from the rear I-beam, and one between the two, demonstrate inventive genius in devising a means of lengthening the arch. But a plurality of transverse supports was disclosed in prior patents, and Girtamer lengthened the arch in the same way by using two beams instead of one. The court says that was anticipated if patentable, though it thought this was wholly within mechanical suggestion.

"Ordinarily, the making of two or more parts out of a thing that had before been used in one part, and using the separate parts to serve the purpose that had been served before the division is not invention," says the court.

WHEN COMBINATION OF OLD ELEMENTS IS PATENTABLE

"However, where a discovery embodies co-acting elements, although they be old, yet, if when brought together in a way not theretofore known, they produce by their interaction a new and useful result, the combination is patentable. (Regent Mfg. Co. vs. Penn. Elec. Mfg. Co., 57 C. C. A., 334); and if one of the elements in the combination be removed or changed so that their interaction is then in another way (in obedience to a different co-operative law), there is nevertheless invention, although the same result is attained, for in that case a different idea of means expresses the discovery, and the new is not an equivalent of the old."

But it further says that whether the change or rearrangement of those elements has, in their co-action, produced the old result in a different way is always a question of fact in any particular case. In the case at bar the court failed to find that the change produced the old result in any different manner. The three elements in combination, whether the brackets be integral or in three parts, were utilized for the same purpose, and perform the same functions in the same way and produce the same result for which they were used in other prior patents.

Fatigue Resistance of Dirty Metal

During the war a series of fifty steels was made by H. W. Gillett of the Bureau of Mines having the rarer metals as principal alloying elements. These steels are now being tested for endurance to repeated bending, especially in the hardened condition. It was found that non-metallic inclusions have a very detrimental effect on such specimens, and an independent investigation on this subject is being planned. The effect on repeated bending tests, of various amounts of lead in wrought brass, and of various amounts of copper oxide in copper is to be studied. This particular phase of the problem was brought up by W. R. Webster, of the Bridgeport Brass Co., as being of importance in itself as well as in its bearing on the general problem.

Book Reviews

Sampling and Analysis of Coal, Coke and Byproducts. Methods of the Chemists of the United States Steel Corporation. Second edition. Published by the Carnegie Steel Co., Bureau of Instruction, Pittsburgh. 184 pages, including many illustrations. Price, $3 (cash with order)

While this book now appears as a second edition, it is virtually a new work, for the old material has been rewritten and revised and many new methods and tests not covered in the former edition are included in the new. In fact the new book is more than double the size of the first edition. The scope and purpose of the work are splendidly given in the preface to this new edition, as follows:

"The first edition of Methods for the Sampling and Analysis of Coal, Coke and Byproducts has served very usefully the purpose for which it was intended. However, the rapid gowth of the byproduct coke industry in this country during the comparatively brief interval since the preparation of the original pamphlet has brought about many changes in byproduct laboratory practice. This consideration led to a decision to rewrite the text, so that the methods described therein could be brought up to date. Accordingly, a committee composed of chief chemists from the largest coal and coke laboratories of the various constituent companies of the United States Steel Corporation was appointed to co-operate in carrying out the work to that end.

"In addition to revising the pamphlet so as to describe the most recent methods employed in coal and byproduct laboratories, it has been deemed advisable to add several new features, among the most important of which are physical tests on coal and coke, the fusibility of ash, and methods for determining sulphur according to the way it exists in coal."

Very frequently industrial plants find it difficult to determine what methods should be used in the laboratory in order to get the most significant commercial results. In the field of coal and coke this has not been as widely true as in some other industries, for there have been standard methods for many of the determinations commonly used, fixed by joint action of the American Chemical Society and the American Society for Testing Materials. Nevertheless it is of great interest to have clearly set forth the methods employed in a large group of laboratories such as those of the Steel Corporation. This work will, therefore, be widely appreciated even by those whose needs are generally met by these standard procedures fixed by societies' committee action and in many cases this work will fill the many gaps still remaining in these standard procedures.

The work should be widely useful in coke-oven plants and in gas works. In fact it promises to be quite as valuable to the gas-works chemist as any other volume, for the methods are given in a clean-cut, understandable style that leaves little opportunity for misunderstanding by the analyst. In this respect the work is worthy of particular commendation, so many of the earlier tests have inextricably mixed discussion of theory, statement of laboratory procedure and incidental comment on interpretation of results. The present volume avoids this complication very happily. It is just exactly what it purports to be, a set of fixed and definite instructions for the laboratory man to follow unincumbered by extraneous discussion which more often than not leads to confusion.

In the teaching of chemical engineering, especially for courses in gas and fuel analysis, this work should also be widely useful. Teachers will do well to include in their course of instruction a clear understanding of such methods as are given, for the student upon graduation will be better able to use the results of a laboratory test if he has had clearly brought to his attention the difference in significance between these tried and proved methods, used with success on a large scale, and the heterogeneous mass of test procedures that accumulate in our literature as the "half-baked" product of small laboratories that lack the vision and commercial experience to get the best results.

R. S. McBride.

Synopsis of Recent Chemical & Metallurgical Literature

Citric Acid and Citrate of Lime

The Department of Agriculture in its Circular 232 entitled "By-Products From Citrus Fruits" by E. M. Chace, gives the following recommended methods for making citrate of lime and citric acid. In this circular it is also suggested that those interested may be able to get additional information from the Laboratory of Fruit and Vegetable Chemistry, 148 South Anderson Street, Los Angeles, Calif.

Citrate of Lime

Boil the juice expressed from lemons or limes with large-grained infusorial earth, in the proportion of from 5 to 10 pounds of the earth to 100 gallons of juice. Separate the infusorial earth and coagulated material from the juice by filtration, bring the juice to boiling again, and neutralize it with ordinary lime or very pure ground limestone. Filter the precipitated calcium citrate, and wash it once or twice with boiling water. If citrate of lime is the end product desired, filter it, dry it thoroughly, and pack in waterproof packages.

Citric Acid

If citric acid is the end product desired, thoroughly mix the calcium citrate with water, in the proportion of 1 to 10 parts, and add an equivalent part of sulphuric acid. Separate the calcium sulphate from the dilute citric acid solution by filtration. Evaporate the filtrate in vacuo, and allow it to crystallize. Redissolve the first crystals, which usually are not of commercial grade, filter them through boneblack, and recrystallize. Mother liquors may be returned to be worked over again with a fresh batch of juice, or they can be repurified by recrystallization.

The main problem in the manufacture of citric acid is to secure a satisfactory container for evaporating the dilute citric acid solution. Wood is the most satisfactory material wherever it can be used. Enamel lined vacuum pans or pans constructed of Monel metal are most favored by those who are manufacturing citric acid on a large scale.

Treatment of Rock-Drill Steel

Messrs. Foley, Clayton and Burnholz will present a "Review of Present Status of Drill Steel Breakage and Heat-Treatment" to the American Institute of Mining and Metallurgical Engineers in February. From an inspection of operations at sixty mines in the Western states, it was found that six had once had pyrometers on their heating furnaces, but five had discarded them. The trouble appeared to be due to small furnaces. In order to get out more drill bits, they were either withdrawn before attaining furnace temperature, or the furnace was greatly overheated. In any case, the pyrometer was useless. Sometimes Le Chatelier optical pyrometers were used to sight upon the hot tip as it rested on the edge of the quenching tank. Under these circumstances, the reading may be within 100 deg. of correct. Magnets are extensively used. A badly overheated bit—where the heat creeps back along the shank—will ordinarily be placed under a faucet to cool before quenching the top. The operator evidently knows that steel should not be quenched from too high a temperature, but does not know that an overheated steel is damaged beyond cure by mere heat-treatment.

Furnace atmospheres are always oxidizing; bits are usually quenched cold in water and not drawn. Under such circumstances the first few blows mushroom the soft cutting edge of a decarbonized bit—if the carbon remains, the very brittle edge is spalled against the hard rock. Either of these tools has about the same life—they work continually in a dulled state. There are so few parallels of this practice of using quenched high-carbon steels to resist impact that one can only speculate upon the advantages to be gained by giving the steel a correct microstructure.

In ten of the mines visited the drills were quenched from the hammer. Thus the finishing temperature varied, also the end strokes given by the smith are always quite light. Consequently the drills would be expected to have quite variable but in general quite large grain size. Even when the steel was

reheated for hardening, it was heated not nearly as far back as it was in the forging heat. In quenching, only ½ to 1 in. of the end is immersed in the water; apparently the heat back of the end is relied upon to creep forward and give the necessary draw.

Variable as is this practice, it is constancy itself compared with the heat-treatment of the shank end. The result is a shank having a Brinell hardness anywhere from 250 to 700. That end of the rod should be hard enough to resist mushrooming, and yet not hard enough to chip itself or the hammer piston. Apparently anything from 250 to 700 Brinell satisfies these requirements, because little or no complaint is heard about breakages there.

Lignite Chars

A new member of the fuel family in Germany has been given the name "grudekoks," which means "embers coke." For some time in the United States we have been hunting for a suitable name for the material that remains after subjecting lignite to a heating process in order to drive off most of the moisture and volatile matter. O. P. Hood, chief mechanical engineer for the Bureau of Mines, the author of an article on grudekoks in a recent issue of *Coal Age*, suggests that the term "lignite char" might be taken as the American equivalent of the German product.

In order to improve lignite as a fuel, it is desirable that a large proportion of its water, from 25 to 40 per cent, be driven off in order to concentrate the fuel values sufficient to warrant transportation and to make a stable product. With the water removed, there remain the ash and about equal parts of volatile matter and fixed carbon. The volatile matter may be more valuable as a source of by-products than as a raw fuel, and also if partly removed the resulting char is mechanically stronger. This material, here called lignite char, is very similar in composition to a Pennsylvania semi-anthracite, but physically it is quite different. In expelling the moisture from lignite the material breaks up into very small pieces.

The material is gray black; it is clean to handle and does not deteriorate in heating value on exposure.

In central Germany the brown coal deposits contain a similar material which when subjected to low-temperature distillation yields a high percentage of tar. It appears in the brown coal bed as lighter colored layers, which are mined separately from the darker material. This lighter colored brown coal is subjected to low-temperature distillation in a circular kiln of simple construction, the resulting char being considered as a byproduct, since the main objective in this process is the paraffine contained in the tar.

No attempt has been made in Germany to briquet this material, since the Germans have found an acceptable way of burning the fine char direct without further processing.

Recent Chemical & Metallurgical Patents

American Patents Issued Jan. 16, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem & Met.* readers. They will be studied later by *Chem & Met.'s* staff and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,442,031—Oil Burning Furnace. G C Adams, California.

1,442,089—Chemical Fireproof Paint. Peter Oosterhouse, Richmond, Mich

1,442,301—Electrical Precipitation of Particles From Gases. W A Sheek; assigned to International Precipitation Co. of Los Angeles, Calif

1,442,304—Apparatus for Treating Material. A R Spencer and W J. Plews, Cleveland.

1,442,317—Recovery of Constituents of Waste Liquor. C. T Whittier; assigned to Royal Baking Powder Co

1,442,318—Preparation of Dry Granular Calcium Acid Phosphate. C T Whittier; assigned to Royal Baking Powder Co

1,442,319—Compressor. E Wilson; assigned to Wilson Eng. Co., St Louis.

1,442,330—Cooling and Refrigerating Solution. N A. DuBois, Massachusetts.

1,442,339-340-341—Albuminous Animal Waste, etc. P Hildebrandt Germany, assigned to Chemical Foundation

1,442,386—Glycols. G O Curme and C O Young, Pittsburgh, assigned to Carbon & Carbide Co

1,442,406—Anhydrite as Source of Substance Which Sets in Presence of Water. R Hennicke; assigned to Kalwerke Salzdefurth A G

1,442,413—Refractory. Z Ollson; part assigned to A R Oppenheim.

1,442,414—Bringing Gases Into Contact With Liquids. W. H Rose, Jersey City.

1,442,420—Reactive Composition. L. H. Baekeland, assigned to Baekelite Corporation.

1,442,485—Production of Fine Powders. W. K. Lewis; assigned to Goodyear Tire & Rubber Co., Akron

1,442,491—Method of Chlorination. J. B. Marvin, Saranac Lake, N. Y.

1,442,494—Treatment of Liquid Waste Containing Combined Carbon. J. E Plimstead, assigned to Jessup & Moore Paper Co, Philadelphia.

1,442,520—Purification Isopropyl Ether. H E. Buc; assigned to Standard Development Co of Delaware

1,442,619—Treating Air. A B Lamb, Washington, D C

1,442,631—Products Made With Cellulose Derivatives. L G Richardson, assigned to American Cellulose & Chemical Manufacturing Co, Ltd., New York City

1,442,743—Process for Making Phenyl Glycerine. C J Strosacker, assigned to Dow Chemical Co., Midland, Mich

1,442,773—Crystalline Product. H A Richmond and R MacDonald; assigned to General Abrasive Co, Niagara Falls

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D C

Extraction of Vanadium, Uranium and Radium From Certain Ores—W. F. Bleecker, of Boulder, Colo., has assigned to the Tungsten Products Co., of Boulder, Colo., the following patent. It has to do with the separation of vanadium, radium, uranium and other compounds from various ores. The process consists first of grinding up the ore to about 20 mesh, adding 50 per cent its weight of sodium carbonate and treating the paste so formed in an autoclave at about 90 lb. pressure at 150 deg. C. temperature. The resulting liquors contain the sulphate obtained by the decomposition of barium and radium sulphate, as well as uranium and vanadium compounds. These are at once filtered off and evaporated in some suitable manner. The barium-radium compounds are separated by means of hydrochloric acid. (1,438,357. Dec. 12, 1922.)

Separation of Chloracetones—When isopropyl alcohol is chlorinated at a temperature of about 65 deg. C., the liquid products of the reaction separate into two layers: a heavy lower layer containing chiefly chlorinated acetones and a supernatant layer containing chlorinated acetones in solution. The chlorinated products consist of dichloracetone (asymmetric), trichloracetone (such as 1.3.3), tetrachloracetone (symmetric), and pentachloracetone. It has been found that the components of such a mixture can be separated by extracting the mixture with water, thereby forming an aqueous solution principally of the tri- and tetra-chloracetones, separating the aqueous solution from the residue, "salting out" the chloracetones from the solution, fractionating the separated chloracetones, extracting the residue above mentioned with an aqueous solution of $NaHSO_3$, thereby dissolving the dichloracetone and, finally, decomposing the solution of dichloracetone to remove this compound from the mixture. (1,436,950. Hyym E. Buc, assignor, by mesne assignments, to the Standard Development Co. of New York. Nov. 28, 1922.)

Guanidine Nitrate—Tenney L. Davis, of Sommerville, Mass., has been granted a patent on a process for the preparation of guanidine nitrate from dicyandiamide, which he claims will give practically double the yield of the present process, involving the intermediate formation of guanylurea. Dicyandiamide and ammonium nitrate, in such proportions that there are present two molecules of ammonium nitrate for each molecule of dicyandiamide, are heated to 160 deg. C. in an autoclave for two to six hours. The dicyandiamide first combines with one molecule of ammonium nitrate to form biguanide nitrate, and upon further heating at a proper tem-

perature, the biguanide nitrate combines with the other molecule of ammonium nitrate to form two molecules of guanidine nitrate. (1,440,063. Dec. 26, 1922.)

Perchlorate Explosives — Numerous attempts have been made to produce an explosive more powerful than or equally as powerful as dynamite, yet possessing superior qualities with respect to stability, economy, resistance to freezing or physiological effect—nitroglycerine headache. Among the proposed substitutes for nitroglycerine dynamite may be mentioned the mixtures of chlorates, sodium or potassium, with resins, gums and nitro-aromatic compounds and mixtures of inorganic nitrates with resins or nitro-aromatic compounds. In general, however, the substitutes have not met with favor because of the low initial sensitiveness and of the tendency of the powder to become hard. Russell M. Cook, of Tamaqua, Pa., has patented an explosive which he claims combines the desirable properties of perchlorate explosives and nitroglycerine dynamite, yet eliminates the undesirable properties of both. A number of formulas are given in the patent disclosure. One example consists of 30 per cent ammonium perchlorate, 7 per cent manganese dioxide, 36 per cent sodium nitrate, 24 per cent TNT, 2 per cent nitroglycerine and tetranitro diglycerine, and 1 per cent chalk.

The purpose of the explosive liquid organic nitrate is to raise the propagation sensitiveness of the perchlorate explosives, so that they compare more favorably in this respect with dynamite, and can be successfully used in special cases in which at present only the more sensitive nitroglycerine dynamite can be applied. The patentee claims that the sensitiveness of the explosive compound is not affected by age. Patent 1,440,768, by the same patentee, covers the use of sodium or potassium perchlorate instead of the ammonium salt. (1,440,767. Jan 2, 1923.)

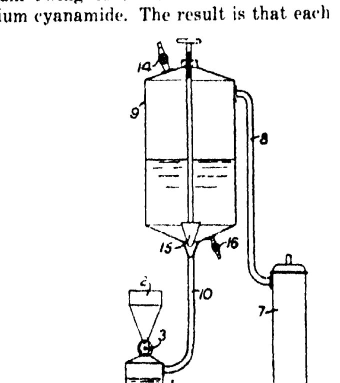
Iodine Compound—Rezso Benko, of Budapest, Hungary, has taken out a patent on a substance which he assumes to be gelatine-hexamethylene-tetramine-di-iodine for which he claims some novel properties. It is said that a solution of the compound is considerably less poisonous than iodine and will, on being introduced into the body by injection, deposit almost its total content of iodine. The substance is made by heating a solution of an albuminoid or a neutralized product of decomposition of an alubuminoid, such as gelatose, with hexamethylene-tetramine-di-iodine, filtering the solution and evaporating to dryness in a vacuum. The compound is said to be readily soluble in water and in glycerine, with a slightly yellow color, forming a yellow precipitate with silver nitrate and giving free iodine with acids. (1,440,813. Jan. 2, 1923.)

Dyeing Cellulose Acetate—The use of trisodium phosphate for the treatment of cellulose acetate artificial silk to render it permeable to dyeing solutions is covered by patent granted to Edouard Paul Sisley of Lyon, France, assigned to Société Chimique des Usines du Rhone of Paris. In an example the artificial silk is slowly agitated for three-quarters of an hour to one hour in a bath containing 25 grams of crystallized dibasic phosphate of sodium and 5 cc. of caustic soda solution 36 deg. Bé. The bath is maintained between 60 and 70 deg. C. during the whole operation. The silk is then thoroughly washed and dried, the loss of weight being 6 per cent. A process can be applied to pure cellulose acetate fabrics or to mixed fabrics, such as cellulose acetate silks and natural silks, or cellulose acetate silk and wool. (1,440,501. Jan. 2, 1923.)

British Patents

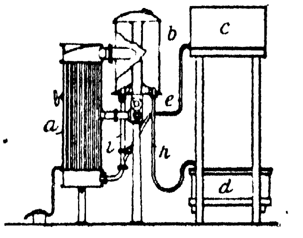
For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England

Cyanamide— In the production of solutions of free cyanamide by gradually adding calcium cyanamide to a circulating body of water or cyanamide solution into which carbon dioxide is admitted, the process is carried out in such a way that the quantity of liquid between the points where the calcium cyanamide and carbon dioxide respectively are supplied is constant and small compared with the total quantity of liquid, notwithstanding the increase in bulk owing to the addition of the calcium cyanamide. The result is that each



addition of calcium cyanamide is only a short time in the liquid before reaching the carbonic acid, and only a small proportion of the liquid is alkaline. Calcium cyanamide is fed from a hopper 2 by a valve 3 into a small tank 1, from which the liquor passes to a pumping device 5 containing a centrifugal wing wheel 11 and mixing vanes 12. Carbonic acid is supplied by a pump 13 and is mixed with the liquid in the apparatus 5. The liquor then passes through a pipe 6 to a cooler 7 if necessary, and thence by a pipe 8 to a large tank 9, which is capable of accommodating the increase in the bulk of the circulating liquor. From the tank 9 the liquor is passed by a valve 15 and pipe 10 to the tank 1. The pipe 8 is preferably tangential to the tank 9 so as to facilitate the escape of gas, which is led off by a pipe 14. The finished solution is withdrawn at 16. (Br. Pat. 186,020. Wargons Aktiebolag and J. H. Lidholm, Wargon, Sweden. Nov. 8, 1922.)

Distillation and Evaporation—In apparatus for evaporating and distilling liquids in which the liquid passes upward through the tubes of a calandria *a* to a vapor-separating chamber *b*, a part of the concentrated liquid flows from the chamber *b* by a pipe *h* to a tank *d*, and the other portion of the concentrated liquid is returned by a pipe *i* to the base of the calandria together with fresh liquid from a tank *c*



and pipe *e*. Part of the vapor evolved in the chamber *b* may be forced by an injector, fan or pump into the space surrounding the tubes of the calandria to serve as heating agent. The apparatus may be used under pressure or vacuum and as an element of a multiple-effect apparatus. In a modified form of apparatus, the end boxes of the calandria are divided by partitions to give the liquid a longer travel, and the fresh liquid is preheated by heat exchange with the concentrated liquor and also with the condensate from the calandria, which may also be used to wash out the tubes of the calandria. The apparatus may be used for the recovery of benzene from oils and greases. (Br. Pat. 185,873. J. L. Ferguson, Glasgow. Nov. 8, 1922.)

Coke—In the production of smokeless fuel and coke, a blend is made of two coals or of coal and coke, semi-coke or ore so that the resinic content of the blend is not less than 5 per cent but preferably not less than 8 per cent of the weight of the blend. This blend is heated to a temperature not exceeding 500 deg. C. or to a temperature of from 50 to 100 deg. C. above the minimum temperature at which the resinic matter is destroyed. To increase the contraction of the blend, the volatiles evolved between 350 and 400 deg. C. should be below 7.5 per cent. Blended coals may be treated as described in specification 175,888—that is, first preheated and then heated to 500 deg. C. and the product subsequently carbonized at 900 to 1,000 deg. C. The products of the process described in specification 164,104 may form part of the blend. (Br. Pat. 186,085. S. R. Illingworth, Brynfedwen, Radyr, Glamorgan. Nov. 15, 1922.)

Arsenic Report Regarded as Too Optimistic

Consideration of Findings of Department of Agriculture Arouses Feeling That Government's Expert Is Prejudiced—Federal Trade Commission to Investigate

STUDY of the arsenic report submitted to the Senate on Jan. 18 by the Secretary of Agriculture leads many chemical specialists to believe that the findings are more optimistic than the situation warrants. The general reaction, and this is supported by letters reaching members of Congress from persons acquainted with the situation, seems to be that the main object of the report was to depress the price of calcium arsenate, or at least check possible advances. It is pointed out that this would be the natural attitude on the part of B. R. Coad, who undoubtedly is responsible for the principal economic deductions in the report. Mr. Coad is in charge of the laboratory which the Department of Agriculture maintains at Tallulah, La. This laboratory was located in the heart of the cotton belt for the specific purpose of studying methods of boll weevil control. It was there that the adaptability of calcium arsenate to that purpose was demonstrated.

THINK COAD PREJUDICED

After having worked out the most promising method ever devised for boll weevil control, Mr. Coad is certain to be keenly disappointed by the interference with its application by the increase in price and lack of the poison. The belief is expressed that, without intending to do so, he has reported on the situation in a way which, to say the least, would not be an additional reason for a further advance in prices.

It also is declared that Mr. Coad's estimate of the demand up to May 1, 1923, is absurdly low. This is particularly the case, it is said, in estimating the requirements for glass manufacture and for the manufacture of lead arsenate. Issue also is taken with his estimate of 3,500,000 tons as being the annual requirement for calcium arsenate.

Many are of the opinion that the demand for white arsenic will increase much more rapidly than its production and that the shortage a year hence will be much more acute than it is today. It is pointed out that the increase in production in the United States will be slow. The output at the smelters can be calculated very closely. Inquiries into the possibilities of production on the part of the Salt Lake Insecticide Co. developed the fact that its production, which will begin about Feb. 1, will not exceed 15 tons a day for a considerable period and while that output eventually can be increased, there is no immediate prospect for the large production in that quarter which some have predicted.

There has been some suggestion that the flexible tariff be applied to calcium arsenate, which is dutiable at 25 per cent ad valorem. In that connection it is pointed out that the manufacturers will not oppose such action, but that it would have very little practical effect, since it would be unprofitable to pay freight on the lime. Arsenic itself is on the free list. All are agreed, however, that the situation cannot be helped materially by imports. The greatest promise for the future lies in Mexico, where it is believed that additional recoveries of arsenic can be secured.

TRADE COMMISSION WILL INVESTIGATE

Without discussion, the Senate approved a resolution offered by Senator Fletcher of Florida providing that the Federal Trade Commission "investigate and report the facts relating to any alleged violations of the anti-trust acts by the manufacturers of, or dealers in, calcium arsenate." Such of the government's specialists who have looked into the calcium arsenate situation, however, are convinced that it is the shortage rather than speculation or combination which is responsible for the enhancement of the price.

On the heels of this resolution, Senator Harris of Georgia introduced a bill to amend the 1922 tariff act so as to place calcium arsenate on the free list. The commodity is not mentioned specifically in the tariff act, but the Customs Division of the Tariff Commission agree that calcium arsenate is dutiable as a chemical salt at 25 per cent ad valorem under paragraph 5 of the act.

Because it is the principal ingredient of calcium arsenate, white arsenic was put on the free list, Senator Harris said, and the evident intention of Congress was that calcium arsenate should be free.

Dr. Miller Reese Hutchison, managing director of the national campaign for boll weevil control of the American Cotton Association, in a letter to the New York *Journal of Commerce* denies that he intends to engage in the manufacture of calcium arsenate. He claims that the efforts of the association are directed toward developing, first, an ample supply of calcium arsenate at a reasonable price; second, an organization to insure that this substance is available to the farmer and to conduct research looking toward improved methods of application and improved insecticides.

Mention is made of the sources from which Dr. Hutchison previously intimated that calcium arsenate could be obtained as follows:

"The publicity that has been laudably given this campaign for the control of the boll weevil has brought out some very interesting and heretofore unknown and unconsidered resources. Among them are several processes for the manufacture of calcium arsenate, which do not require the white arsenic of commerce. It is from such sources that the tonnage, in excess of that pronounced available by governmental and other agencies, will be secured."

COUNTERVAILING DUTIES ANNOUNCED

Instructions for the assessment of countervailing duties on imports of calcium acetate were issued to collectors of customs on Jan. 23 by the Treasury.

The Treasury listed the duties imposed on calcium acetate in various countries as follows: Belgium, free; Germany, 1 gold mark per 100 kilos; Hong Kong, free; Japan, 0.41 gold yen per 100 kin; Mexico, 0.07 gold peso per kilo, plus additional surtaxes amounting to 12 per cent of the duty; Netherlands, free; Norway, free; Panama, 15 per cent ad valorem; Sweden, acetate of lime, raw or purified, 0.03 gold crown per kilo; United Kingdom, 11⅓ per cent ad valorem.

5,000 Research Problems Concern Agriculture

More than 5,000 research projects are under way at the agricultural experiment stations throughout the country, it is announced by the Department of Agriculture. They include many problems involved in fertilizer requirements, the study of soils, the control of pests and other work which requires the application of chemistry.

Meat Packers Perfect Development Plans

Establishment of a national institution combining broad educational, research and trade association facilities is assured for the meat packing business, according to an announcement by the Institute of American Meat Packers in the name of Thomas E. Wilson, of Chicago, chairman of the organization's "development plan commission." Mr. Wilson's statement, in part, follows:

Sufficient funds now have been subscribed by the meat packers of America to begin actual development of the Institute plan. This plan provides for the ultimate development at Chicago of a comb ned educational institution, research institute, trade association and industrial museum.

Approximately $150,000 has now been subscribed by the meat packers of the United States to cover the necessary surveys and initial developments during a 3-year period. These special subscriptions are entirely in addition to the regular revenues received by the Institute for carrying on its present educational and trade activities.

Systematic instruction will be provided for men already engaged in the industry as well as for men intending to enter the industry. The packers of the United States have authorized the creation forthwith of a bureau of industrial education and the engagement of an educator of distinct on in this field to direct it. A thorough-going survey of the educational possibilities and difficulties of the American meat-packing industry will be made, and future provision for instruction—respecting both methods and kinds—will be shaped largely by the results of the survey.

Similarly a bureau of scientific research will be established at once and a competent director of standing engaged. A survey of the scientific problem of the industry will be made. It is believed that much duplication of research can be eliminated and that many research projects can be undertaken which would be too costly or of too general benefit to justify their prosecution by an individual company. It is believed that co-operative research will effect many savings and solve many scientific problems of the industry on which information is now incomplete. Nor is it believed that such a plan will interfere with the research work done by individual companies in their respective plants and laboratories.

In the same way provision has been made for creating without delay a bureau of packinghouse practice and research. This bureau, directed by an expert on packinghouse operations, will function in furtherance of purposes similar to those just mentioned.

Development of the plan will mean the creation of an institution which combines with the research and technical educational facilities of Continental industrial institutes the trade activities and exposition features of American business associations.

Engineers Urge Study of Gold and Silver Situation

That more than mining engineers are interested in legislation proposing to study the situation which will overtake silver mining when the Pittman act expires is indicated by a communication received by the Senate Committee on Mines and Mining from the Federated American Engineering Societies. The Committee on Mines and Mining is considering legislation proposing to set up a Congressional committee, along the lines of the Committee on Agricultural Inquiry, to study the silver and possibly the gold situation. The letter from the Federated Societies reads as follows:

"Engineers in all branches of the profession are much interested in the welfare of the metal-mining industry and in the activities which depend directly and indirectly upon that industry. For that reason, the Federated American Engineering Societies wishes to urge on your committee the advisability of a careful study of the problems which this nation is facing as a result of the handicaps which surround the production of gold and which soon will envelop the production of silver.

"Since these matters concern many more activities than those immediately involved, the engineers of the country are much interested in seeing the entire subject illuminated as much as possible.

"This organization, therefore, urges that your committee report favorably some such legislation as is now before you and asks that no effort be spared to secure the enactment of the bill at this session of Congress."

European Conditions to Be Discussed at Joint Meeting

A joint meeting of the four chemical societies having sections in New York City will be held in Rumford Hall, Friday, Feb. 9, under the auspices of the American Electrochemical Society. W. S. Landis, chief technologist of the American Cyanamid Co., will be the principal speaker, his subject being "European Conditions," a discussion of impressions received on his recent trip abroad.

J. S. Negru, managing editor of *Chem. & Met.*, will lead the discussion.

C.W.S. Corrosion Report Delayed

Recent announcement in *Chem. & Met.* of the report prepared by the Chemical Warfare Service on "Corrosion of Metals and Materials by Acids and Alkalis" has resulted in a large number of requests for this report to the Washington office of C.W.S. That Service regrets that there has been a temporary delay in supply of this document and that it is impossible at once to comply with the requests which have been made. However, it is hoped that an ample supply may be prepared and made available for distribution in the near future, at which time those who have requested it will be supplied.

Mining Engineers to Meet in February

Three Days Devoted to Technical Sessions at 127th Meeting

The 127th meeting of the American Institute of Mining and Metallurgical Engineers will occur at the Engineering Societies Building, New York, Feb. 19 to 22, 1923. A summary of activities interesting to metallurgists is shown below:

MONDAY, FEB. 19

2 p.m.—Session on Breakage and Heat-Treatment of Drill Steel.

2 p.m.—Session on metallurgy; considering heap leaching, zinc electrolytes, pyritic smelting, and gold recovery.

4 p.m.—Second annual lecture of Institute of Metals; "Solid Solutions," by Walter Rosenhain.

8 p.m.—Smoker.

TUESDAY, FEB. 20

2 p.m. Institute of Metals.

"Nature of Solid Solutions," by Edgar C. Bain.

"Cored Crystals and Metallic Compounds," by Edgar C. Bain.

"Some Observations on Occurrence of Iron and Steel in Aluminum," by E. H. Dix, Jr.

"Polishing Aluminum and Its Alloys for Metallographic Study," by E. H. Dix, Jr.

"Density and Expansivity of Aluminum-Silicon Alloys From 20 to 1,000 Deg. C.," by J. S. D. Edwards.

"Practical Spectrographic Analysis," by W. F. Meggers, C. C. Kiess, F. J. Stimson.

8 p.m.—Motion pictures and dance.

WEDNESDAY, FEB. 21

9.30 a.m.—Session on Iron and Steel.

"Continued Discussion on Physics of Steel," by W. R. Webster.

"Specifications for Foundry Pig Iron," by Richard Moldenke.

"Influence of Temperature, Time and Rate of Cooling on Physical Properties of Carbon Steels," by H. M. Howe, F. B. Foley and J. H. Winlock.

2 p.m.—Discussion on Technical Education.

2 p.m.—Institute of Metals Division.

"Occurrence, Chemistry and Uses of Selenium and Tellurium," by Victor Lenher.

"Determination of Gases in Metals," by Harold L. Simons.

"Study of Bearing Metals," by C. H. Bierbaum. (Illustrated.)

"Tests on High-Tin Bearing Metals," by P. W. Priestley.

"Bright Annealing of Copper Wire," by P. E. Demmler.

"Thermal Conductivity of Some Industrial Alloys," by H. M. Williams.

2 p.m.—Iron and Steel Session.

"Deterioration of Malleable in the Hot Dip Galvanizing Process," by W. R. Bean.

"Heating and Cooling Curves of Large Ingots," by F. E. Bash.

"Possibilities in Application of Colloid Chemistry to Production of Clean Steel," by H. W. Gillett.

"Low-Temperature Brittleness in Silicon Steels," by Norman B. Pilling.

6:45 p.m.—Annual dinner.

THURSDAY, FEB. 22

Excursion to American Brass Co.'s plants at Ansonia, Conn.

Long-Expected Exposition Report Appears

Salesmen's Association Suggests Plans to Improve Annual Chemical Show Which It Is Hoped Will Appease Everybody

FOR THE PAST three months a committee of the Salesmen's Association of the American Chemical Industry has been considering possibilities and plans for a new departure in the conduct of the Chemical Exposition. During and immediately after the last exposition—which was the eighth annual affair of the kind—considerable sentiment was voiced in disapproval of the present management. It was noised about that an opportunity to be of genuine service to the industry was being sacrificed to commercialism and that the price demanded of exhibitors was greatly in excess of the benefits they derived from their displays.

At the height of the dissatisfaction, the plan of holding a co-operative exposition designed to interest and attract representatives of the chemical industry rather than manufacturers of equipment was proposed by Adriaan Nagelvoort, who purposed to conduct such an effort in 1923. This program enlisted the interest of many in the industry, while others felt that the management of such a spectacle should be left to a private company which had the necessary experience and facilities.

The Salesmen's Association, in an attempt to weigh the merits of the opposing plans and decide on a course which would be of maximum benefit to the industry, appointed the committee whose report has just been completed. Briefly, the Salesmen express the belief that the exposition should be continued, presumably by the old management, with special and intensive efforts to improve its quality and to work with representatives of the industry for the ultimate good of the latter.

Extracts From Report

Extracts from the report follow:

This report presents a plan for getting more tangible results. It records also definite accomplishments towards putting this plan into effect. The committee agrees that in its fundamentals this plan is sound and practical; its details are purposely left flexible.

Elements Necessary to Success

To make the exposition a truly national chemical meeting and market place, a congress of scientific trade and consuming associations must be held and so guarantee the attendance of many desirable visitors.

To carry on the logical purpose of educational work to the public, students and chemical consumers a constructive, consecutive program must be worked out.

To accomplish this end the management of future expositions must work closely in co-operation with the industry. Policy must be guided and plans controlled by what the industry, as a whole, believes is for the common good, and this control is just and proper because the support of the industry is virtually a franchise creating a monopoly in chemical shows. Even a private corporation conducting the exposition must fairly share the profits with the industry.

The attendance problem can best be solved by holding a congress of chemical and consuming industries. A common program, to avoid conflicts, can provide common entertainment features with one gigantic chemical industry banquet. The meetings of the participating associations would have to be a new and special type, devoid of routine business and paper reading, designed as get-together gatherings to discuss one or two big fundamental problems of broad interest.

Exposition Co. Contributes $5,000

At the instance of your committee the directors of the International Exposition Co. voted Jan. 15 to turn over to the advisory committee 5 per cent of the gross receipts of the coming Ninth Chemical Exposition. This sum, which Mr. Payne estimates at not less than $5,000, is to be spent by the advisory committee for the common good of the industry, on educational and other work in connection with the exposition.

The question of better representation for the executive and sales departments of the industry upon the exposition's advisory committee has been taken up with their chairman, Dr. Charles H. Herty.

Dr. Herty has invited your committee to meet with the advisory committee in order to confer on the new personnel of the advisory committee and to lay before them suggestions and offers of co-operation which we have received from many associations, firms, colleges and individuals in response to our questionnaire which was the subject of our preliminary report.

Naglevoort Withdraws 1923 Plans

After further consultation with your committee, Mr. Nagelvoort has agreed to withdraw definitely his tentative plans for a co-operative show in 1923. He takes the liberal view that the measure of co-operation with the industry which the International Exposition Co. offer should be tried fairly, and for the common good desires not to put the least obstacle in the way of hearty, united co-operation. We commend his attitude and indorse the sentiments he expresses.

While this report has been in preparation most of the feeling on the subject has died out and the report is not likely to arouse any great enthusiasm. Cooler heads in the industry look for a Chemical Exposition in 1923 much like its predecessors, although it seems probable that the late controversies will serve as a word to the wise.

Program of Joint Safety Engineering Meeting Announced

The need for and use of national codes relating to safety in the operation and maintenance of elevators and in building construction are the two principal subjects on the program of the joint meeting of the Engineering Section of the National Safety Council and the American Society of Safety Engineers called for Friday, Feb. 16, in the Engineering Societies Building, New York City.

The different phases of elevator safety will be discussed by D. L. Lindquist, chief engineer, Otis Elevator Co.; M. H. Christopherson, deputy commissioner, New York State Department of Labor; C. B. Connelley, commissioner, Pennsylvania Department of Labor and Industry; C. W. Old, vice-president, Shur-Loc Elevator Safety Co., Inc., New York; C. W. Bassett, associate engineer, Elevator Supplies Co., Hoboken, N. J.

George T. Fonda, chairman of the Engineering Section of the National Safety Council and a member of the firm of Fonda-Tolsted, Inc., Washington, D. C., will preside at the afternoon meeting on the proposed national building code. Those who will lead the discussion are: Ira H. Wilson, chairman, United States Department of Commerce; Sidney J. Williams, chief engineer, National Safety Council; and a representative of the New York State Industrial Commission. The motion picture "Paying the Price," depicting the dangers in neglecting minor injuries, will be presented by A. D. Risteen, director of technical research, Travelers Insurance Company.

The public safety problem of adequate control will be considered at an evening session. Richard E. Enright, New York City Police Commissioner; H. K. Maples, field secretary, American Automobile Association; David Van Schaack, Aetna Life Insurance Co., and others will discuss the subject.

British Interests Investigate Canada as Site for Paper Mill

Another striking evidence of the intention of prominent British firms to locate branches in the overseas dominions came to light recently with the arrival of the Empress of France at a Canadian eastern port, with a party of civil engineers representing the famous shipbuilding firm of Armstrong-Whitworth of Newcastle-on-Tyne. The immediate object of the party is to investigate the prospects of locating a pulp and paper plant in Newfoundland, presumably at Port aux Basques. In addition to this, however, the information was given out that coincidental with this development in Newfoundland it is the intention of the Armstrong-Whitworth interests to investigate similar prospects in the Province of Quebec, to which end arrangements have already been made for the reorganization of the company's Canadian headquarters at Montreal.

Dye Makers and Importers Reach Impasse

Difficulty Lies in Defining Competitive Products Entitled to Higher Duties Under American Valuation

Committees representing dye manufacturers, importers, manufacturing importers and consumers met at the U. S. Appraiser's Stores in New York City, Jan. 25, for the purpose of assisting in drafting rules and regulations to govern the appraisement of imported dyes. Special Deputy Appraiser John Donnelly, who presided, declared that the primary purpose of the meeting was to consider tentative lists of non-competitive dyes which under the new tariff are entitled to entry at comparatively low rates of duty. Thomas L. Doherty, customs adviser of the Synthetic Organic Chemical Manufacturers Association, reported that the dye makers were not willing to prepare lists of competitive or non-competitive colors until the customs authorities indicated how they were going to interpret that part of the tariff law which provides that "any coal-tar product shall be considered similar to or competitive with any imported coal-tar product which accomplishes results substantially equal to those accomplished by the domestic product when used in substantially the same manner."

Appraiser Donnelly said that the American manufacturers had been given the same opportunity as the importers to prepare their lists and in view of the fact that they had thus failed to coöperate with him, he declared the meeting adjourned. The rules and regulations, he said, would be worked out by the customs authorities in consultation, with the importers, consumers and manufacturing importers.

Dr. Herty's Views

In explaining to *Chem. & Met.'s* representative the stand which the manufacturer's had taken, Dr. Charles H. Herty, president of the producers' association, pointed out the difficulties involved in defining the term "competitive," particularly from the manufacturer's viewpoint. "The importer," he said, "has nothing to lose and everything to gain in preparing his lists. If he includes a domestic made product among his non-competitive dyes, the only one to suffer would be the American maker. On the other hand, if the manufacturers put a color on the non-competitive list and later found that a domestic producer had already spent a large sum of money in developing the product, his entire investment might be wiped out by a single large importation."

Whether two dyes are competitive or not should be decided on the basis of degrees or respects in which the products are similar, according to Dr. Herty. Thus if the appraiser were to agree that dyes are competitive when they are similar in respect to color, or fastness, or chemical composition, or method of application, etc., it would be comparatively easy to prepare such a list.

A.C.S. President Will Visit Thirty-Two Sections

Announcement is made of the itinerary of E. C. Franklin, newly elected president of the American Chemical Society, in his speaking trip over the country. Prof. Franklin will speak in the following cities on the dates noted:

Los Angeles, Calif.,	March 16
Houston, Texas,	March 19
New Orleans, La.,	March 21
Nashville, Tenn.,	March 22
St. Louis, Mo.,	March 24
Pittsburgh, Pa.,	March 26
Morgantown, W. Va.,	March 27
Maryland,	March 29
Boston, Mass.,	April 9
New York, N. Y.,	April 11
Philadelphia, Pa.,	April 12
New Jersey,	April 13
Lehigh Valley,	April 14
Rochester, N. Y.,	April 16
Syracuse, N. Y.,	April 17
Cornell, N. Y.	April 18-19
Buffalo, N. Y.,	April 21
Akron, Ohio	April 23
Cleveland, Ohio,	April 24
Detroit, Mich.,	April 25
Ann Arbor, Mich.,	April 26
Midland, Mich.,	April 27
East Lansing, Mich.,	April 30
Notre Dame, Ind.,	May 1
Lafayette, Ind.,	May 2
Urbana, Ill.,	May 4
Evanston, Ill.,	May 7
Milwaukee, Wis.,	May 8
Madison, Wis.,	May 9
Iowa City, Iowa,	May 11
Ames, Iowa,	May 14
Minnesota, Minneapolis and St. Paul,	May 16-17

Professor Franklin's talk before most of the sections on this occasion will be "The Ammonia System of Compounds—Experimentally Illustrated."

Conduct Research on Kerosene Fuels

The research laboratories of Carnegie Institute of Technology, Pittsburgh, have undertaken experiments to determine the relative efficiency of kerosenes and oxidized kerosenes as fuels. In accordance with the policy of the Institute to link up its educational facilities with modern industry, the department of chemical engineering has been conducting a series of tests to determine the relative merits of various oils as usable fuels. The completion of this important work should go a long way toward solving the problem of oil conservation, by the possible development of a new fuel.

According to a report by J. H. James, head of the department conducting the experiments, oxidized kerosenes cause less "knocking" than straight kerosene when used in a kerosene engine. The tests also showed that oxidized kerosenes have approximately the same power development as ordinary kerosene, in spite of the fact that their thermal value is one-eighth less. Dr. James attributes the efficiency of the oxidized kerosenes to the better "clean up" in the combustion of these partially oxidized fuels.

The success of the experimental work at Carnegie at this stage gives promise that oxidized kerosene, which is manufactured by catalytic oxidation from low-grade petroleum, may become a useful fuel in the future. Its properties may cause it to be used industrially in kerosene engines or blended with gasoline for use in gasoline engines.

Midgley Awarded 1923 Nichols Medal

Work on Gaseous Detonation and Anti-Knock Compounds Wins Award of American Chemical Society

The Nichols medal, awarded each year by the American Chemical Society to the author of the most exceptionally meritorious paper published during the year in the society's journals, has been awarded to Thomas Midgley, Jr., of the General Motors Corporation. Mr. Midgley's remarkable work in the development of anti-knock compounds for internal combustion engines is too well known to require elaboration here. The medal will be presented on March 9 by C. A. Browne, chairman of the New York Section, as Dr. Nichols, who was asked to make the presentation, will be in California at that time.

Wilder D. Bancroft, of Cornell, will also speak at this meeting, on Midgley and various aspects of his work. Mr. Midgley will review the effects of anti-knock compounds on gaseous detonation and then emphasize the fact that to all intents and purposes the anti-knock property is a new property of matter which can be truly ascribed to one element in the compound and that the groups bonded to this atom modify its behavior. His remarks will be illustrated with slides and be accompanied by experiments.

Industrial Alcohol Situation Improved, Says Doran

The industrial alcohol situation is in far better condition as regards denaturing of the product and its use illegally as liquor than it was a year ago, according to J. M. Doran, head of the industrial alcohol division of the prohibition unit, while reports to the division indicate that the legitimate industry is enjoying a period of prosperity with plants running to capacity.

Newspaper reports which were current shortly after the first of the year to the effect that much of the illicit liquor supply was due to industrial alcohol being misused were grossly exaggerated, according to Dr. Doran, who declared that the basis probably was a series of arrests and several suspensions of permits to consumers. These developments were the result of long work by the prohibition unit, Dr. Doran declared, and not connected with an influx of liquor during the holidays.

Conditions Under Control

The unit has been successful in cleaning out a number of fraudulent permitees who were securing industrial alcohol on the plea of need for manufacturing purposes but in reality for illegal use, Dr. Doran asserted, and has had close co-operation with industrial alcohol producers in this effort.

"From the prohibition standpoint, conditions a year ago were alarming but are now well under control," said Dr. Doran. "Progress has been surprisingly satisfactory and I never felt better about the situation than now."

Ceramic Society to Hold Silver Jubilee in Pittsburgh

Plans for General Session, Divisional Meetings and Plant Visits Reflect Endeavor to Surpass All Previous Efforts

Since the publication in our last issue of the program of the refractories division for the American Ceramic Society meeting at Pittsburgh, Feb. 12 to 16, announcement has been made of plans for the other divisional meetings, the general session and plant visits. The meeting will open with a general business and technical session in the ballroom of the William Penn Hotel, Monday, Feb. 12. That evening will be devoted to a banquet in honor of charter members. Industrial divisions will meet Tuesday and Wednesday at the Fort Pitt Hotel. Plant visits will be made Thursday and Friday. During the entire week an exhibition of ceramic products will be held at the Fort Pitt Hotel.

Although the program is still incomplete, the following excerpts will indicate the effort which is being exerted to make this meeting the best ever held

GENERAL BUSINESS AND TECHNICAL SESSION

Presidential address, Frank H Riddle

Research—Its Relation to a Manufacturing Executive, B. E. Sallsbury.

Theory and Practice in Refractories, J D Ramsey

The Art of Manufacture and the Manufacture of Art, Charles F Binns

The Industrial Benefits From Co-operation in Research Through the Enamel Division, DeWitt F Riess.

International Critical Tables of Numerical Data of Physics, Chemistry and Technology, E. W. Washburn

A Simple Method of Measuring Color, A E. O. Munsell

ENAMEL DIVISION

A Cause of the "Specking" of Ground Coat Enamels, R. R. Danielson and T. D Hartshorn.

Sand Blasting of Cast Iron for Enameling Purposes, F. G. Jaeger

Relative Action of Acids on Enamels, E P. Poste

The Intermittent Type of Gas-Fired Enameling Furnaces, H. H. Clark.

A Study of Some Substitutes for Tin Oxide and Their Effect on Opacity, R R Danielson and M. K. Frehafer.

Zirconia in Enamels, W. F. Wenning.

Some Relations Between the "Fit" and the Mechanical and Chemical Properties of Enameled Ware, R. R. Danielson and B T Sweely.

The Use of Bentonite for Suspending Enamels, M. E. Manson.

There will also be discussions on fuels and furnaces for enameling, use of silicon carbide refractories for enameling furnace muffles, transparent enamels, single coat gray enameled ware

HEAVY CLAY PRODUCTS DIVISION

Experiences With Dutch Kilns, Roy A Horning.

Construction Features of Importance to Clay Plants, T W. Garve.

Wastes That Should Be Eliminated in Heavy Clay Products Manufacturing, M. W Blair

A Recent Installation of a Harrop Car Tunnel Kiln, Frank M. Hartford

Automatic Stoker for Firing Heavy Clay Products Kilns, John Martin

Some Calculations Involved in the Drying of Clay Wares, Hewitt Wilson.

GLASS DIVISION

Better Gas—Better Combustion—Better Begin, W. B. Chapman

The Resistance of Soda Lime Glass to Water, L. A. Palmer.

A Study of the Tendency of Glass to Take Up Moisture, K. L. Ford.

The Advisability of Pure Research on Glass in American Universities, Alexander Silverman.

Res'stance of Soda Lime Glass to Water, A E. Williams.

Cold Clean Artificial Gas and a Discussion of the General Properties of Gaseous Fuels, A. E. Blake.

Furnaces for the Melting of Glass in the Laboratory, A. E. Badger and C. D. Spencer.

A Skiagraphic Study of Fabricated Glass Articles, C. D. Spencer and A. E Badger.

Glass Wool Heat Insulation in Europe, Arthur D. Saborsky.

A Study of the Origin and Cause of Stones in Glass, Herbert E Insley

Results of Mechanical Tests on Window Plate and Rolled Sheet Glass, Arthur E. Williams.

Tensile Strength of Glass, J. T. Littleton

TERRA COTTA DIVISION

Mold Shop Practices, T. A. Klinefelter.

Monograph of Ceramic Literature on Terra Cotta Subjects, Hewitt Wilson.

A Study of a Group of Slip Clays of the United States, Paul E Cox and Mark A Taylor.

Various Materials Used for Patching Terra Cotta, C. W. Hill.

Tests Used for Barytes in Terra Cotta Work, W. L Howatt

Scheduling in Terra Cotta Plant, Pensyl Mawby.

A Group of Slip Clays of the United States, Paul E Cox and Mark A Taylor.

Magnesium Chloride Cements, C R. Hill, Dow Chemical Co

WHITE WARES DIVISION

A Better Design for a Jug Mold Clinch, Paul E. Cox

A Study of Plasticity with Practical Potters' Methods, Paul E. Cox and D. A Moulton

Recent Developments in Control and Operation of Modern Kilns, T A. Jeffrey, L E Jeffrey and T. R. Harrison.

Further Studies of Porcelain Glazes Maturing at High Temperatures, Robert Twells, Jr.

Preliminary Experiments in Use of American Ball Clays in General Ware Bodies, F K. Pence

Heat Distribution of the Updraft Kiln, Albert V. Bleininger.

Colloquium on Feldspar, led by Edward Schramm

Colloquium on Saggers, led by Walter A. Hull

ART DIVISION

Papers on subjects outlined as chapters of a book on modern pottery practice will form a large part of the Art Division program. In addition, however there will be numerous papers on related topics

PLANT VISITS

Plants to be visited have been divided into seven groups, members having a choice of four trips (1 to 4 below) on Thursday, Feb. 15, and three trips on Friday, Feb. 16.

Trip 1—Fallston Fire Clay Co., Fallston, Pa.; H. C. Fry Glass Co., Beaver Falls Art Tile Co., Mayer China Co., all at Beaver Falls, Pa.

Trip 2—American Window Glass Co., Arnold; Allegheny Plate Glass Co., Glassmere; Heidenkamp Plate Glass Co., Springdale.

Trip 3—Standard Sanitary Mfg. Co., Pittsburgh Clay Pot Co., U. S. Glass Co., Willets Co., Woods-Lloyd Co., Mellon Institute.

Trip 4—Clairton plant, Carnegie Steel Co.; Donora plant and zinc works of American Steel & Wire Co.

Trip 5—East Liverpool district. Homer Laughlin China Co., Golding & Son, plant 1; Hall China Co., R. Thomas & Sons Co.

Trip 6—National Works, National Tube Co., McKeesport; Harbison-Walker Refractories Co., Hays; by-product ovens, Jones & Laughlin Steel Co., Hazelwood.

Trip 7—Westinghouse Electric & Mfg. Co., Universal Portland Cement Co., Universal, or High Voltage Insulator Co., Derry.

Personal

C. F. BLUE, president and director of the Carbon Steel Co., Pittsburgh, Pa., has resigned.

C. D. GARRETSON, general manager and director of the Electric Hose & Rubber Co., Wilmington, Del., has been elected president of the company, succeeding GEORGE S. CAPELLE, who becomes chairman of the board of directors. Mr. Garretson has been connected with the company for 19 years.

R. S. GOSROW of Chicago has been engaged as electrometallurgist for the Manitoba Power Co., Ltd., and the Winnipeg Electric Railway Co., Winnipeg, Man.

BENJAMIN G. LAMME, chief engineer of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., was the recipient of the Joseph Sullivant medal from the Ohio State University, Jan. 12, his alma mater, which he received for notable engineering achievements.

A. M. MADDOCK, an official of Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of sanitary ware, gave an interesting illustrated address on the subject of "Early Pottery and Its Development" before the Men's Association of the First Presbyterian Church, Trenton, Jan. 15.

CHARLES PIEZ, president of the Link-Belt Co., Chicago, addressed the annual meeting of the Engineers' Society of Western Pennsylvania, Pittsburgh, Jan. 22, on "Some Problems of the Day."

C. J. RAMSBURG, vice-president of the Koppers Co., Pittsburgh, addressed the Cleveland Section of the American Chemical Society, Jan. 26, on "Coke."

Dr. OWEN L. SHINN, professor of applied chemistry, University of Pennsylvania, will supervise a course of ten lectures on chemistry for the instruction of salesmen, to be given under the direction of the Chemical Club of Philadelphia, Pa.

L. J. TROESTEL, a member of the Bureau of Chemistry, dust explosion staff, has resigned to accept the position of chief chemist of the American Refractories Co. at the Joliet, Ill., plant. Mr. Troestel leaves Washington about the middle of February to assume his new work in Joliet.

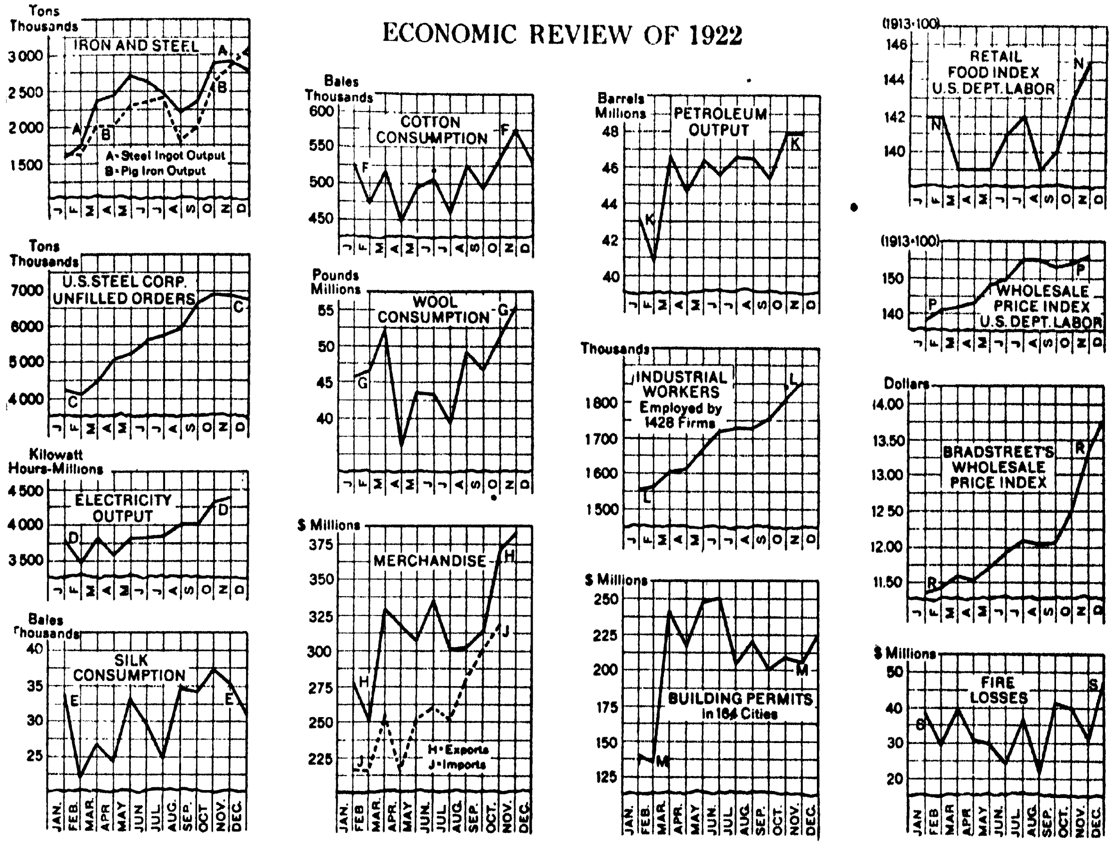
R. C. WELLS spoke before the Chemical Society of Washington on Jan. 11, presenting his address as retiring president, on the subject, "Chemistry of the Sea."

The American Chemical Society, Louisville Section, has elected the following officers: C. E. BALES, chemist of Louisville Fire Brick Works, president; T. J. BOSMAN, of the Federal Chemical Co., vice-president; C. E. GEIGER, of the Louisville Testing Laboratory, secretary-treasurer, and A. W. HOMBERGER, of the University of Louisville, councilor.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers



THE TREND OF PRODUCTION AND CONSUMPTION DURING 1922 *Copyrighted by Irving Bank, New York*

Economic Review of 1922

Summary of Production, Consumption and Prices in the Country's Basic Industries

STATISTICAL evidence is now available definitely to confirm the earlier predictions that 1922 was a year of business expansion. Practically all of the great basic industries showed astonishing improvement during the 12 months ended Dec. 31, 1922. Not only has the volume of output measurably increased, but sales and prices have bettered considerably. Of the sixteen economic factors which form the basis of a business review of 1922, published in the January bulletin of the Irving Bank (see accompanying tables and charts) fifteen showed improvement in December (or last available month), as compared with the beginning of the year. Silk consumption alone was less in December than in January. The improvement ranged between 0.19 per cent in the case of cotton consumption and 87.5 in the output of pig iron.

Action and Reaction in Business

Readjustments Will Continue Until Overexpansion Period Is Balanced —Babson Predicts Possibilities of Early Reaction

According to the cyclic theory of business, action and reaction must be approximately equal—in other words, depression in business must be followed by compensating activity, and *vice versa*. With this theory in mind, it is of interest to consider the question which is so often heard of late: Are we approaching a period of inflation? It would appear the present period of readjustment must be continued until it has compensated for the preceding period of overexpansion. Boom times will not come again until the reaction from the orgy of 1920 is completed.

In forecasting the trend in the commodity situation during 1923, the statistical organization headed by Roger Babson has recently stated that there are possibilities, at least, for an early reaction and a temporary setback in present activity. The statement is as follows:

"The main points in the commodity situation for 1923 are (1) The upward swing will lose momentum, reaching a peak in early 1923; (2) There is a strong possibility of a reaction before

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	175.15
Last week	174.21
January, 1922	144
January, 1921	181
January, 1920	242
April, 1918 (high)	•286
April, 1921 (low)	140

As cottonseed oil continued to rise in price it has favorably affected the index number, which showed a gain during the week of practically one point. The strength shown by caustic potash and the carbonate was sufficient to offset the effects of lower prices for caustic soda and acetic acid.

the year is over; (3) The average price of commodities for the year will be higher than in 1922. Index numbers during the next few months may be somewhat higher, but this prospect does not justify heavy buying. We are in a very sensitive period. Purchases in most cases should be limited to the early part of this year. Only those products that are relatively low should be bought from the long-swing standpoint."

Potash Salts and Imported Chemicals Advance in New York Market

Most Chemical Prices Are Firmly Maintained, Although the Demand Is Not Up to Manufacturers' Expectations—Lead Pigments Advance With Metal

NEW YORK, Jan. 29, 1923.

THE European disturbances are already reflected in the New York market and practically all imported chemicals are in a much firmer position than a week ago. In addition the negotiations of the German potash syndicate have tended to direct interest toward the potash salts. As a result caustic potash, the carbonate, permanganate and perchlorate are being quoted at higher prices on the spot market and stocks are none too plentiful.

Arsenic continues to be scarce and prices are correspondingly high. Caustic soda recorded a fractional decline for export, due presumably to competition from England. Imported lots of barium chloride were slightly lower on spot. Bichromates were in moderate demand, with supplies limited. Sal ammoniac was quite difficult to locate in round lots and holders are firm in their belief that prices are due for a sharp advance.

All lead pigments recorded increases due to the sharp rise in the metal. Standard, dry, white lead was quoted at 9¾c. per lb., in casks, carload basis. Formaldehyde, oxalic acid, bleaching powder, nitrite of soda and prussiate of potash continued along moderate active lines, with practically no change of importance recorded. Camphor was quoted lower, due to recent heavy arrivals from Japan.

HIGH-SPOTS IN THE MARKET

Arsenic—Several fair-sized sales were reported at 15½c. per lb. Nearby shipments were quoted at 15@15½c. per lb.

Barium Chloride—A few lots of imported material were offered somewhat lower on spot at $90 per ton. The general range, however, was around $95@$100 per ton. The demand continued moderately active.

Carbonate of Potash—Leading sellers quoted higher prices on all grades of imported goods. The 80-85 per cent calcined on spot sold at 6c. per lb., with the 96-98 per cent at 7½c. per lb.

Caustic Potash—Higher quotations for 88-92 per cent imported were recorded. Demand continues very active with large interests quoting as high as 7¾c. per lb. The general range is around 7@7½c. per lb.

Caustic Soda—There has been very little demand for export and prices were lower around $3.40@$3.50 per 100 lb., f.a.s. Spot goods for domestic consumption was quite limited, with odd lots sold at $3.75 per 100 lb., ex-store. Contracts at the works remained unchanged.

Chlorate of Potash—Spot quotations remained very firm in sympathy with the general strength of other potassium salts. Importers named 7½c. per lb. for crystal and powdered, with domestic figures around 8½c. per lb.

Permanganate of Potash—Prices on spot are sharply higher, due to the scarcity of supplies and strong demand. Several holders of odd lots named 17½c. per lb. for U.S.P. goods. The general range was around 17½c. per lb.

Prussiate of Soda—Some holders reported sales at fractionally higher levels, while others were still quoting 18½c. per lb. The general range was 18½@19c. per lb. Shipments from abroad were much firmer, with 20c. per lb. the lowest price c.i.f. N. Y., duty paid.

Silicate of Soda—Large producers quoted lower prices on 60 deg. material, with $2 per 100 lb., f.o.b works, carload basis heard as the regular quotation. The 40 deg. test remained around 80c. per 100 lb., f.o.b. works. The demand was merely routine.

Camphor—Large dealers reported lower prices on spot goods, due to the heavy arrivals from the Orient. Several transactions were recorded around 86c. per lb., with the range around 86@87c. per lb.

VEGETABLE OILS

Linseed Oil—The spot market held quite firm, with several large crushers practically sold up for January shipment. January oil held around 90c. per gal., carload basis, in barrels. Forward shipments were somewhat easier, with March quoted at 85c. per gal., in barrels, carload lots.

Castor Oil—There was very little change in prices recorded during the interval, although the market showed a very firm appearance. Producers quoted AA grade at 12¾c. per lb., with No. 3 at 12½c. per lb., carload lots, in barrels.

China Wood Oil—The spot market ruled quite firm and prices were advanced to 18c. per lb., a new high level for the past year. Supplies abroad were reported quite scarce and leading dealers are looking forward to a much higher market. March-April-May shipments from China were quoted at 15c. per lb.

Coconut Oil—Although demand was rather dormant, prices ruled steady throughout the week. Ceylon type oil held around 8¾c. per lb., sellers' tanks, prompt shipment. Spot oil in barrels was quoted around 9¾c. per lb.

Soya Bean Oil—A fair-sized tonnage of crude material was reported sold at 10⅝c. per lb., tanks, f.o.b New York. Spot oil in tanks was quoted around 10½c. per lb. The general inquiry was only moderate.

More Activity With Firmer Market at St. Louis

Very Few Price Declines as Volume of Trading Shows Material Increase—Glycerine Market Unsettled

ST. LOUIS, Mo., Jan. 24, 1923.

Since our last report a material increase in the volume of business transacted is to be reported and future prospects are very encouraging. Prices generally are firm. The European disturbances will undoubtedly reflect upon the American market and bring about higher prices.

ALKALIS HOLDING WELL

Conditions in the alkali market are very firm and prices are still holding well. The volume of business is good with a chance of increasing from now on. *Caustic soda* in 5-drum lots is being quoted at \$3.90 per 100 lb. for the solid and \$4.25 for the flake, delivered buyer's door *Soda ash*, 58 per cent light in 5-bag lots can be had at \$2.10 per 100 lb., with the regular differential of 20c. for barrels over bags. Carload business goes at about \$1.85 per 100 lb. *Sodium bicarbonate* in small lots from 3 to 5 bbl. is going strong at \$2.40 per 100 lb., and some sales are being made as high as \$2.50. *Sal soda* has not held its own with the other alkalis and the volume of sales is not as large as could be expected. However, it is expected that sal soda will be higher soon.

GENERAL AND SPECIAL CHEMICALS

Trading in heavy *mineral acids* is exceptionally good, also showing a material increase in volume and the market is much firmer. Stocks of *citric acid* are in good volume, but the demand only along quiet lines. *Oxalic acid* manages to hold its own. *Ammonia water* 26 deg. is showing some improvement and a very satisfactory business is being done. *White arsenic* continues to be very scarce. The demand for *carbon bisulphide* continues to improve and a very nice business is reported on this article. *Copperas* is moving in a routine manner and the market remains unchanged, with supplies somewhat easier. *Glycerine* is very unsettled and apparently no one knows just what the market is. Prices range from 17½@18½c. lb. Contracts are being made at various prices and spot goods also are being sold at various prices. A settled market is now in sight. *Lead acetate* has advanced recently, but the demand is rather quiet; however, this article should show more activity very soon. *Sulphur* is moving along in rather a routine manner. The volume of sales is only moderate and prices are not over strong. Sales are beginning to pick up slightly, but are not yet what they should be. *Zinc spelter*, while quiet, is still moving in fair volume. This also is the case with *zinc dust*. Both have been very firm and a change in price is not looked for very soon. *Zinc sulphate* is in very good demand and quoted in carload lots at 3¼c. f.o.b. St. Louis, and less than carload lots at 3¾c. f.o.b. St. Louis.

OILS AND PAINT MATERIALS

Castor oil has taken a very stiff increase and has now reached 14c. a lb. in drums. It may go higher and manufacturers are frank to admit that the market is tending that way. *Turpentine* has again gone skyrocketing and touched \$1.67 per gal. in single barrels and \$1.61 in 5-bbl. lots—quite an increase from when we last reported. *Linseed oil* is holding firm and the demand is very good. Higher prices are almost inevitable and users are purchasing as much as possible while prices remain at the present level.

Paint grinders are optimistic for the coming season and are buying freely. Several carloads of dry-earth colors have been purchased for shipment via New Orleans.

Buoyant Tendency Seen in Steel Market

Infrequent Price Advances Noted as General Activity Shows Marked Increase

PITTSBURGH, Jan. 26, 1923.

The general tone of the steel market has further improved in the past week. There has been continuous improvement since early in December. The market has indeed now come to display a buoyant tendency, since there is now a liberal sprinkling of price advances, whereas in November the average mill would probably have been well satisfied with a guarantee of continuance of the prices then existing, some of which were being shaded not infrequently.

MANY PRICE ADVANCES

Hoops, formerly quotable at a range of 2.75@2.90c. according to gage and other conditions, are now at 2.90c. as minimum, with some unattractive orders going as high as 3.25c. For a time there were sales, to particularly favorite buyers, at 2.60c. and even 2.50c.

Technically, merchant steel bars are quotable at 2@2.10c., but the 2c. price seems to be for rather late and uncertain delivery or to apply on special contracts, as for steel involved in large fabricated steel contracts. In November the top of the market was 2c., with various concessions.

Wrought-iron pipe has been advanced four to six points, according to size, on black, and two points extra on galvanized, while double extra strong is advanced six to ten points, uniformly on black and galvanized.

The National Tube Co. has issued a new list on welded steel boiler tubes, dated Jan. 23, decreasing discounts by three points on all sizes except 1¾ in., which is unchanged. The new basing discount is 48 per cent on less than carloads, making 52 per cent on carloads. The advance is followed by all independents. Producers have been well sold up for some time past.

An advance in merchant steel pipe and oil country goods is expected at any time and in some quarters is regarded as overdue, considering the sold up condition of mills and the pressure for deliveries.

The American Steel & Wire Co., while not following the recent advance of independent mills of \$2 a ton on plain wire and 10c. a keg on nails, has adopted new extras, annealing plain wire being \$3 a ton extra, while the basis for galvanizing is increased from 50c. to 60c. a hundred pounds on the base gages and additional advances are made for other gages.

An important point in the general price situation is that the United States Steel Corporation is participating in the price advances, though not in all cases. Until recently it appeared to be the general policy of the corporation to avoid any advance at all.

Independent sheet mills are now sold up much better than they were at the beginning of December, several being very well filled to April 1, beyond which date they are indisposed to obligate themselves. The advance recently predicted is likely to occur for second quarter, and will probably be \$3 a ton, to 3.50c. for black sheets and 4.50c. for galvanized sheets. The Steel Corporation is not a feature in this situation, since it is already sold up into June at the prices ruling for months past.

COKE AND PIG IRON

Since about the first of the year the common expectation has been that arrangements would be made removing the possibility of a bituminous coal strike April 1. The actual agreement has been signed in the past week. In December the prevailing opinion was that there would be a mining suspension, and part of the steel demand then running was supposed to be an anticipation of that mining suspension. The altered condition, however, does not seem to have affected steel demand adversely.

The Connellsville coke market has not weakened on account of the change in labor outlook, prices being sustained largely by there being a continued scattered demand for heating coke, amounting to a fair volume altogether, with occasional inquiry from blast furnaces on account of delayed deliveries on contracts. The market is \$8@\$8.25 on furnace coke and \$9.25@\$9.50 on foundry coke, with a possibility that \$8.50 might have to be paid, in an emergency, for the best furnace coke.

The pig iron market continues decidedly sluggish, on the whole, as to new buying, but furnaces seem to be fairly well sold up, while consumers are taking full deliveries and in some cases endeavoring to anticipate. Consumers are evidently in expectation that prices are much more likely to be lower than higher in the near future, on the ground that coke can hardly avoid declining. The market is quotable at \$27.50 for bessemer, \$25@\$26 for basic and \$27@\$28 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being \$1.77.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 39 - $0 41
Acetone, drums	lb	.21 - .21½
Acid, acetic, 28%, bbl	100 lb	3 25 - 3 50

Financial. Construction and Manufacturers' News

Construction and Operation

Alabama

MOBILE—The Great Southern Roofing Co., recently organized with a capital of $125,000, has leased a local building for the establishment of a new plant for the manufacture of composition roofing specialties. A power house and new tank storage building will be constructed. T. J. Larkin is president.

SHEFFIELD—Samuel W. Kendall, Meridian, Miss., is completing the organization of a company to construct and operate a cement manufacturing plant in this section. The Kelley quarry property, near the government's nitrate plant No. 2, has been acquired and work will soon be commenced on the initial units, with total capacity of about 2,000 bbl. per day. It is also proposed to install a limekiln, which will be ready for service at an early date. The cement plant unit will be completed early in July. The works are estimated to cost close to $100,000, including machinery.

Arkansas

EL DORADO—The Evans-Thwing Refining Co., 624 Finance Bldg., Kansas City, Mo., is completing plans and will soon commence the construction of a new oil refinery on site selected at El Dorado, estimated to cost about $500,000, including machinery. The general contract for the structural work has been awarded to the George H. Siedhoff Construction Co., Wichita, Kan.

California

LOS ANGELES—The California Flax Seed Products Co. has awarded a contract to the Austin Co., Pacific Electric Bldg., for the erection of a new 1-story plant 75x100 ft., on 26th St., near Santa Fe Ave., estimated to cost approximately $18,000.

OAKLAND—The California Salt Co., Mills Bldg., San Francisco, has tentative plans under consideration for the rebuilding of the portion of its plant on San Francisco Bay, near Oakland, destroyed by fire, Jan. 14, with loss approximating $300,000, including equipment.

WALNUT CREEK—The Pacific Cellulose Co. will establish a chemical plant in connection with its proposed new local mills for the manufacture of artificial silk. The former works of the Diablo Glove Co. has been secured, with a 6-acre tract of land for the erection of additional buildings. Dr. C. A. Schwartz is vice-president, and E. A. Schwartz secretary and treasurer.

SAN FRANCISCO—The Standard Oil Co., 200 Bush St., is planning for the construction of a new storage and distributing plant on the North Beach, foot of Jones St., with initial capacity of 30,000 bbl.

Connecticut

WATERBURY—The American Brass Co. has awarded a contract to the Tracy Brothers Co., Waterbury, for the erection of a new 3-story building at its plant, 80x100 ft.

Georgia

ATLANTA—The Union Seed & Oil Co., Mason Ave., has plans under way for the rebuilding of the portion of its plant, destroyed by fire, Jan. 14, with loss of about $15,000.

Idaho

COEUR D'ALENE—The Independence Lead Mines, Ltd., is considering plans for the erection of a new mill at its properties, with initial capacity of about 100 tons per day. R. M. Atwater, Jr., is company engineer in charge. Harry B. Kingsbury is president.

Illinois

STERLING—The Black Silk Stove Polish Co. is completing plans and will soon take bids for the erection of a new plant, 3-story, 128x130 ft., estimated to cost approximately $80,000. Ashby Ashby & Schulze, West Jackson Blvd., Chicago, are architects. L. K. Wynn is president.

CHICAGO—Bauer & Black, 2500 South Dearborn St., chemists and drug manufacturers, have purchased property on 26th St., between Dearborn and Federal Sts., for a total consideration of $110,000, and will use the site for extensions in their plant. The proposed factory will approximate 100x100 ft.

CHICAGO—The Chicago Fiber Box Co., recently organized, has leased space in the building at 833 Rees St. for a term of years, for the establishment of a new plant.

Indiana

SEYMOUR—The Silverstone Stucco & Plaster Products Co., 220 Indiana Pythian Bldg., Indianapolis, recently organized, has commissioned Merrit, Harrison & Turnock, 500 Board of Trade Bldg., Indianapolis, to prepare plans for its proposed new plant to be erected at Seymour, for the manufacture of stucco and plaster products. The main structure will be 1-story, 50x96 ft. John R. Briggs is president.

Iowa

WATERLOO—The Rath Packing Co., Sycamore and Elm Sts., has revised plans in preparation for the erection of a new building at its plant for the manufacture of fertilizer products. Henschien & McLaren, 1637 Prairie Ave., Chicago, Ill., are architects. J. W. Rath is president.

MADISON—The Hinde & Dauch Paper Co., Sandusky, O., contemplates the erection of a new mill at the foot of Occidental St., for the manufacture of paperboard products.

Kansas

WICHITA—The Western Glass Co., 531 North Market St., has plans in preparation for the erection of a new 2-story and basement building 75x100 ft., on North Market St., to cost about $35,000. Edward Forsbloom, Sedgwick Bldg., is architect.

Kentucky

LEXINGTON—The Red Top Coal Co., recently organized, is planning for the establishment of a new local plant for the manufacture of smokeless powder to be used for blasting service in connection with its coal-mining operations.

OWENSBURG—Bolger & Medley are considering plans for the erection of a new local plant for the manufacture of brick and tile products.

Louisiana

BOGALUSA—The Bogalusa Paper Co. has plans in progress for the erection of an addition to its plant, to include 5 new buildings, with machine department, 55x300 ft.; finishing department, 150x150 ft.; beater department, 96x140 ft., general mill, 60x80 ft.; and generator building, 95x140 ft. The structures will be used for the manufacture of kraft papers, increasing the output from 90 to 125 tons per day. The plant, exclusive of machinery, will cost about $350,000, with equipment installation estimated to cost about $600,000 additional. James L. Carey, 208 North Laramie Ave., Chicago, Ill., is engineer.

MONROE—The Gulf Carbon Co., Baltimore, Md., recently organized under Maryland laws with a capital of $250,000, has plans under way for the erection of a new plant at Monroe, where a site of about 3 acres of land has been purchased. It is purposed to provide equipment for a daily output of about 8,000 lb. The plant is estimated to cost close to $200,000, with machinery. William A. Gillespie, Union Trust Bldg., Baltimore, is secretary and treasurer.

Maryland

LAUREL—The Lapsey & Brothers Co., 30 South Hanover St., Baltimore, will install a special mechanical drying department at its proposed new plant at Laurel, for treating and drying of painted shade cloth. A mechanical painting works will also be provided. The complete equipment installation is estimated to cost about $100,000.

BALTIMORE—The Continental Roofing & Mfg. Co., recently organized, has acquired the factory of the McHenry-Millhouse Mfg. Co., for the establishment of a new plant for the manufacture of coal-tar and composition roofing products. Thomas M. Riangard heads the company.

Massachusetts

WATERTOWN—The Hood Rubber Co., Nichols Ave., manufacturer of tires and other rubber products, has awarded a contract to the Aberthaw Construction Co., 27 School St., Boston, for the erection of a 3-story addition to its plant, totaling about 9,600 sq.ft. in area. F. C. Hood is general manager.

HOLYOKE—The Chemical Paper Mfg. Co. has acquired the local mill of the United States Envelope Co., and will use the property for extensions in its present works on Jackson St. The United States company will remove the machinery now at the factory to its plants in other cities.

Michigan

DETROIT—The Codde Brass & Aluminum Mfg. Co., care of Robert Finn, 622 McKerchey Bldg., has awarded a contract to Alfred R. Yops, 3072 Maybury Ave., for the erection of a new 1-story foundry, 50x110 ft., estimated to cost about $15,000.

SAGINAW—The United States Graphite Co. has preliminary plans in progress for the erection of a new 1-story plant on Holland St. Cowles & Mutscheller, Chase Bldg., are architects. Harry C. Woodruff is vice-president.

PLYMOUTH—The Lee Foundry & Machine Co., 120 Mill St., manufacturer of iron and steel castings, has commissioned Christian W. Brandt, 1114 Kresge Bldg., Detroit, architect, to prepare plans for a 1-story foundry addition, to cost $30,000.

Minnesota

ST. CHARLES—The Minnesota Gold Mining Co. will take bids early in February for the erection of a new 1-story ore reduction plant at Elba, near St. Charles, to cost about $125,000, including machinery. A. Miles Bean, Denver, Colo., is engineer. E. M. Gainey is secretary.

Missouri

KANSAS CITY—The Kansas City Gas Co., a subsidiary of the United Gas Improvement Co., Broad and Arch Sts., Philadelphia, Pa., is considering the erection of a new 1- and 2-story addition to its artificial gas plant.

New Jersey

TRENTON—The Trenton Potteries Co., North Clinton St., manufacturer of sanitary ware, has commenced the erection of a new addition at the plant of its Equitable Pottery, Lalor and Hancock Sts., to cost approximately $100,000. It will consist of a pressing shop, drying department, and kiln room, 70x110 ft. William A. Klemann, 1st National Bank Bldg., is architect.

New York

LAUREL HILL—The Nichols Copper Co., 25 Broad St., New York, has filed plans for the immediate construction of a 3-story addition to its plant at Laurel Hill, L. I., 41x57 ft., estimated to cost about $25,000.

ROCHESTER—The Dominion Feldspar Corp., has completed plans and will commence the erection of a new grinding mill, 63x104 ft., at its plant at the Genesee Dock, foot of Boxart St.

North Carolina

CHARLOTTE—The J. B. Davis Concrete Products Co., 901 Davidson St., is planning for the construction of a new plant, 50x150 ft., for the manufacture of septic tanks and other concrete products. The equipment installation will comprise mixers, molds and kindred apparatus. J. B. Davis is president.

Ohio

AKRON—The National Sulphur Co., 80 Maiden Lane, New York, has plans in progress for the erection of an addition to its new plant at North Akron, soon to be placed in operation. It will cost about $75,000, including equipment. The company is removing its former works at Bayonne, N. J., to the new location.

ASHLAND—The Faultless Rubber Co. has awarded a contract to the Camp Construction Co., 520 Newman Stern Bldg., Cleveland, for the erection of a 1- and 2-story

addition to its plant, to be used for general rubber and acid service, 46x135 ft. The Osborn Engineering Co., 2848 Prospect Ave., South, Cleveland, is engineer.

Oklahoma

HOCKERVILLE—The St. Louis Smelting & Refining Co. has work in progress on 2 new concentration plants, one to be located near the Ontario lead smelter and the other on the H. E. Ambo property. The mills are estimated to cost in excess of $175,000

TULSA—The Peer Oil Corp is being organized with a capital of $5,000,000 and 1,000,000 shares of common stock, no par value, to take over and merge the Kansas & Gulf Co., 332 South Michigan Ave, Chicago, Ill., the Monarch Oil & Refining Co and the Southern Petroleum Co The new corporation will operate properties and refineries in Oklahoma, Arkansas, Kansas, Louisiana and Texas, and plans for extensive increase in production The present gasoline plants have a rated capacity of 10,000 gal. per day

WYNNEWOOD—The Texas-Pacific Coal & Oil Co, Fort Worth, Tex, will commence the immediate erection of a new oil-refining plant on local site, estimated to cost close to $1,000,000, including machinery

MIAMI—The Chanute Smelter Co., Joplin, Mo., is said to have closed negotiations for an extensive tract of local lead and zinc properties, totaling about 5,000 acres. Development will be commenced at an early date. A plant is projected

Oregon

HUNTINGTON—The Columbia Cement Co Concord Bldg Portland, has plans nearing completion for the erection of a new cement-manufacturing plant on local site, estimated to cost in excess of $500,000, including machinery The company is operating with a capital of $2,000,000

Pennsylvania

HELLAM—A. J Hershey, Hartman Bldg, York, Pa., is having plans prepared for the construction of a new 1-story clay reduction plant on site near Hellam, to be 30x60 ft., estimated to cost about $20,000 John Crowe, Hartman Bldg., York, is architect

PHILADELPHIA—The Garrett-Buchanan Co., 18 South 6th St, manufacturer of paper products, has filed plans for the erection of a new building at its plant to cost about $55,000

MIDLAND—The Crucible Steel Co of America, Oliver Bldg., Pittsburgh, is completing plans for the erection of a new 1-story liquid purification plant at its Midland works, estimated to cost $60,000. The Koppers Co, Union Arcade, Pittsburgh, is engineer.

READING—The Philadelphia & Reading Railroad Co, Reading Terminal, Philadelphia, has commenced the erection of a new oil storage and distributing plant at Reading, with capacity of about 200,000 gal It will be 75x150 ft., and is expected to be ready for the equipment installation early in the spring.

South Carolina

MANNING—The Manning Oil Mill has been acquired by F. D. Hunter and associates. The new owners plan extensions.

Texas

ROCKDALE—The Austin Petroleum Co., Inc., Austin, will soon commence the installation of additional equipment at its local oil refinery for general increase in production. W. H. McClanahan is secretary and manager.

BEAUMONT—The Atlantic Refining Co., 3144 Passyunk Ave., Philadelphia, Pa., has acquired a tract of land of about 500 acres on the Neches River, and plans to use the site for a new oil-refining plant.

HARLINGEN—The Rio Grande Tire & Rubber Co. has commenced the erection of a new local plant for the manufacture of automobile tires and other rubber products. It is estimated to cost close to $50,000.

STAMFORD—The Chickasha Cotton Oil Co., Chickasha, Okla., has preliminary plans under way for the erection of a new oil mill at Stamford, to cost approximately $150,000, including machinery.

TEXAS CITY—The Pierce Oil Co., is planning for extensions in its local plant to cost close to $20,000. A. W. Grant is superintendent.

BRECKENRIDGE—The Central Gasoline Producing Co. is planning for the immediate rebuilding of the portion of its local refining plant recently destroyed by fire with loss of about $32,000.

Industrial Developments

PAPER—The International Paper Co., New York, has increased production at its different mills to a normal basis, with a schedule of close to 1,900 tons output per day, or at the annual rate of 580,000 tons of newsprint. During 1922 the total production was 422,809 tons. The company has advanced the wages of skilled employees at the mills, averaging about 30 per cent of the total working forces, from 6 to 7 per cent over the previous wage level. About 900 operatives are affected.

The paper mills at Holyoke, Mass., giving employment to from 5,500 to 6 000 workers, have advanced the wage scale from 5 to 8 cents an hour, depending upon occupation The increase became effective Jan 15

The Uncas Paperboard Co, Norwich, Conn, recently organized, has commenced operations in a remodeled portion of its new local mill, formerly the plant of the Ironsides Board Corp, idle for about 1½ years past Additional improvements will be made at the mill.

CERAMIC—The International Brick Co, El Paso, Tex., is advancing production at its plant and is now running on a basis of 80,000 brick and tile per day, as compared with a previous output of 70,000 daily. The working force has been materially increased A large part of the output is for Arizona work.

The Crescent China Co., Niles, O., is completing the erection of a new plant at Alliance, O., and plans for early operations

The P Bannon Pipe Co., Louisville, Ky, is maintaining regular operations at its plant, with normal working force, and is said to have orders on hand to insure production on this schedule for some time to come

The Acme Brick Co., Denton, Tex, has resumed production at its plant and plans to develop capacity at an early date. Additional machinery will be installed to provide for a maximum output of about 60,000 bricks per day A. B Kelley is general manager

Kiln placers in the potteries in the East Liverpool, O, district, including plants at East Liverpool, and Wellsville, O, and at Chester and Newell, W. Va, recently out on strike, have returned to their work. The men were recently granted a wage advance of 7 per cent, and have now asked that pottery companies defray one-half the wages of the "pin boy," who is a member of each pottery crew, and paid by the kiln placers The request has been refused.

The Vallejo Brick Co Vallejo, Calif., is operating at capacity at its plant, and has plans under way for extensive additions for increased output. It is purposed to create a fund of about $100,000 for the expansion.

Workers in the sanitary ware branch of the pottery industry at Trenton, N. J., are still out on strike, although the plants are filling the positions with other men. About 5 000 men and women are now said to be idle

The Glenwood Shale Brick Co, Erie, Pa., is maintaining capacity production at its plant, and expects to continue on this basis throughout the winter season.

RUBBER—The Fiske Rubber Co., Chicopee Falls, Mass, is advancing production at its different plants, and practically capacity output is now operative. The works, in addition to the local mill, include the factories at Springfield, Mass., Pawtucket, R. I., and Milwaukee, Wis., with present daily output of 24,500 casings and 32,500 tubes.

The Dunlop Tire & Rubber Co., River Rd, Buffalo, N. Y., is making ready for initial production at its local mill and will make an expenditure of approximately $750,000 for the installation of necessary equipment and improvements in present machinery. It is expected to give employment to a working force of about 5,000 persons, and to advance this at the rate of 150 employees a month for a number of months to come. It is expected to develop an output of 2,500 tires per day. Edwin B. Germain is president.

The Miller Rubber Co., Akron, O., manufacturer of automobile tires, has opened a new plant, recently completed, to be used for the manufacture of rubber gloves. The company is resuming this line of production after a discontinuance since 1920.

The Goodyear Tire & Rubber Co., Akron, O., has refused the demand of employees at the plant for a wage advance of 15 per cent. The company has increased the wage scale 7½ per cent since last July.

IRON AND STEEL—The Colorado Fuel & Iron Co., Denver, Colo., with mills at Pueblo, Colo., is arranging to blow in 4 additional furnaces at its plant in the Silver City, N. M., district at an early date.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., a subsidiary of the United States Steel Corp., is breaking all previous production records for pig iron at its furnaces. During December a total of 81,000 tons was produced.

The Youngstown Sheet & Tube Co., Youngstown, O, is planning to blow in an additional blast furnace at its plant at an early date. The company has recently resumed at a number of sheet mills.

The present steel mill capacity in the Niles, O, district, is now about 88 per cent of normal A total of 45 of the 51 mills are in active production.

The N. & G Taylor Co., Cumberland, Md, manufacturer of tin and terne plate, is maintaining regular production at its local mills, with close to normal working force

The Gulf States Steel Co, Birmingham, Ala, is developing maximum production, with its ingot mill at capacity and finishing mills now on double turn.

The Reading Iron Co., Reading, Pa., has recently advanced the wages of puddlers at its mills to $9 80 a ton, as compared with a previous scale of $8 80 a ton. A proportionate advance has also been made in the tonnage rates of other material. Common labor has been increased from 30 to 33 cents an hour. A total of 6,000 men are affected by the change, which became operative Jan. 15

MISCELLANEOUS—The Great Texas Oil & Refining Co, Breckenridge, Tex., is planning for the early operation of its new oil refinery on local site, now nearing completion. The plant will have a capacity for handling 5,000 bbl. of crude oil per day, with refining facilities for producing 500 bbl. of lubricating oils and other petroleum byproducts daily. It will represent an investment of close to $1,000,000.

The Electric Hose & Rubber Co., Wilmington, Del, manufacturer of heavy rubber hose for air brake and other service, has adopted a night shift at its plant, in addition to regular day operations. The company is said to have orders on hand to insure this basis of output for about 6 months to come.

The Hudsondale Ochre Works, Hudsondale, Pa., is increasing production at its plant, and has recently added a night shift in addition to the regular day force.

The National Enameling & Stamping Co., New York, is operating its metal plants in the Baltimore, Md., district at practically full capacity, and will continue on this schedule for an indefinite period.

The Lancaster Foundry Co., Lancaster, Pa, manufacturer of iron and steel castings, has resumed production at its plant after a shut down since early last July. Employment will be given to about 75 operatives.

Capital Increases, etc.

THE DIAMOND CRYSTAL SALT CO., St. Clair, Mich., has filed notice of increase in capital from $1,500,000 to $2,050,000.

THE SUPERIOR GUANO CO., 4th Ave. and Clinton St., Baltimore, Md., manufacturer of fertilizer products, has arranged for an increase in capital from $100,000 to $250,000.

THE SOUTHWESTERN COTTON OIL CO., Oklahoma City, Okla., has arranged for an increase in capital from $100,000 to $500,000, for proposed expansion.

THE HEGLER ZINC CO., Danville, Ill., has filed notice of increase in capital from $380,000 to $2,000,000, for expansion.

THE AMERICAN GLUE CO., 121 Beverly St, Boston, Mass., is disposing of a note issue of $2,500,000, a portion of the proceeds to be used for expansion and additions to working capital.

THE BUCK GLASS CO., Fort Ave. and Orange St., Baltimore, Md., has arranged for an increase in capital from $150,000 to $250,000.

THE AMERICAN HARD RUBBER CO., 11 Mercer St., New York, N. Y., has filed notice of increase in capital from $5,000,000 to $7,500,000.

THE CLIPPERT BRICK CO., Springwells, Mich., has increased its capital from $100,000 to $700,000, for general expansion.

THE HAMMERMILL PAPER CO., Erie, Pa., is disposing of a preferred stock issue of $3,000,000, a portion of the proceeds to be used for additional working capital.

THE LEHIGH PORTLAND CEMENT CO., Allentown, Pa., has arranged for an increase in capital from $18,000,000 to $25,000,000.

New Publications

PAMPHLETS, ETC.

THE BUSINESS LAW JOURNAL is the title of a new monthly publication, which will contain the current important commercial decisions of the state and federal courts. Each issue will present 50 to 60 such decisions. Each decision will be set forth at sufficient length to explain the facts, the question presented, the court's conclusion, and the reasoning upon which the same is based. The following is a partial list of the subjects under which the decisions will group themselves: Corporations, insurance, sales, contracts, railroads, banking, negotiable paper, mortgages, bankruptcy, brokers, taxation, mining, workmen's compensation, and the decisions of the Federal Trade Commission dealing with unfair competition. Each issue will also contain articles dealing with practical problems of commercial law and recent legislation affecting business. The magazine is intended for the use of business men, manufacturers, bankers, accountants, credit men, etc. Its object is to keep them in touch with the current business decisions, especially those in which a loss has been unnecessarily sustained. The editor will be John Edson Brady, who since 1910 has been editor of the *Banking Law Journal*. The magazine is published by the Business Law Journal Co., 71 Murray St., New York City. The subscription price is $8 per year.

THE UNITED STATES PUBLIC HEALTH SERVICE, Treasury Department, has issued Reprint 748 on "Physiological Effects of Exposure to Low Concentrations of Carbon Monoxide," by R. R. Sayers, F. V. Meriwether and W. P. Yant; Reprint 770, "Dermatosis Following the Use of Cutting Oils and Lubricating Compounds," by William J. McConnell, and Reprint 786, on "The Effect of Gasoline Fumes on Dispensary Attendance and Output in a Group of Workers," by Octavius M. Spencer.

THE DOMINION BUREAU OF STATISTICS, Ottawa, Canada, has issued a booklet on "Chemical and Allied Products—1919 and 1920" and "Coal Statistics for Canada" for the calendar years 1919, 1920 and 1921.

THE DIVISION OF ENGINEERING of the National Research Council has just issued a booklet giving much information about its organization, work and personnel. The National Research Council is a co-operative organization of American societies and scientific men concerned with the physical, mathematical and biological sciences, and the applications to human welfare through the agricultural, engineering and medical arts. Approximately eighty societies are included. The main offices of the Council are at 1701 Massachusetts Ave., Washington, D. C., pending the completion of its permanent building near the Lincoln Memorial. The Division of Engineering has offices in the Engineering Societies Building, 29 West 39th St., New York, to facilitate co-operation with the engineering societies and the Engineering Foundation.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: I: 16, Secondary Metals in 1921, by J. P. Dunlop (Mineral Resources of the U. S., 1921, Part 1), published Oct. 17, 1922; I:17, Gold Silver, Copper Lead and Zinc in California and Oregon in 1921, by Charles G. Yale (Mineral Resources of the U. S., 1921, Part 1), published Oct. 23, 1922; I:20, Gold, Silver, Copper, Lead and Zinc in Montana in 1921, by C. N. Gerry (Mineral Resources of the U. S., 1921, Part 1), published Nov. 17, 1922; II 34, Coke and Byproducts in 1919-1920, by R. S. McBride and F. G. Tyron (Mineral Resources of the U. S., 1920, Part II), published Oct. 18, 1922; II:35, Manufactured Gas and Byproducts in 1920, by R. S. McBride (Mineral Resources of the U. S., 1920, Part II), published Dec. 12, 1922.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circ. 24, Publications of the Bureau of Standards; Circ. 86, U. S. Govt. Specification for Turpentine; Circ. 102, Specification of Composite Vehicle for Thinning Semipaste Paints When the Use of Straight Linseed Oil Is Not Justified; Circ. 134, Specification for Fire-Extinguishing Liquid (Carbon Tetrachloride Base); Circ. 135, Caustic Magnesia Cement; Scien. Paper 444, Practical Spectrographic Analysis, by W. F. Meggers, C. C. Kiess and F. J. Stimson; Scien. Paper 448, Decarburization of Ferrochromium by Hydrogen, by Louis Jordan and F. E. Swindells; Scien. Paper 452, Structure of Martensitic Carbon Steels and Changes in Microstructure Which Occur Upon Tempering, by Henry S. Rawdon and Samuel Epstein; Scien. Paper 453, Preparation and Properties of Pure Iron Alloys by Robert P. Neville and John R. Cain; Scien. Paper 457, Gases in Metals: 1. The Determination of Combined Nitrogen in Iron and Steel and the Change in Form of Nitrogen by Heat-Treatment, by Louis Jordan and F. E. Swindells; Tech. Paper 218, Results of Some Compression Tests of Structural Steel Angles, by A. H. Stang and L. R. Strickenberg; Tech. Paper 219, Effect of Temperature, Deformation and Rate of Loading on the Tensile Properties of Low-Carbon Steel Below the Thermal Critical Range, by H. J. French; Tech. Paper 222, Relative Usefulness of Gases of Different Heating Value and Adjustments of Burners for Changes in Heating Value and Specific Gravity, by Walter M. Berry, I. V. Brumbaugh, J. H. Eiseman, G. F. Moulton and G. B. Shawn; Tech. Paper 223, Reclamation of Used Petroleum Lubricating Oils, by Winslow H. Herschel and A. H. Anderson.

Industrial Notes

THE HAZARD ADVERTISING CORP., 7 East 42nd St., New York City, announces that H. Gardner McKerrow, formerly advertising manager of the National Aniline & Chemical Co., has recently joined the organization. Mr. McKerrow's long experience in the textile and chemical industries has given him an understanding of processes and methods that will enable the Hazard agency, which specializes on technical accounts, to extend its service for technical clients.

F. J. Low recently resigned as vice-president of the agency with which he was associated for more than 6 years and has organized an advertising agency under the name of F. J. Low Co., Inc., with offices at 15 West 44th St., New York City. Mr. Low was for many years advertising manager of H. W. Johns-Manville Co. and has also been associated with the advertising of the Chicago Fuse Mfg. Co., American Steam Gauge & Valve Mfg. Co., the Schaeffer & Budenberg Corp., Sarco Co., Inc., and other concerns in the technical field.

STEWART-THILL Co. is the new name of the Walter L. Flower Co. of St. Louis, district representative of the Conveyors Corp. of America, Chicago. The personnel of the organization remains the same and offices will be continued at 312 8th St., St. Louis.

The directors of GIFFORD-WOOD Co., Hudson, N. Y., at a recent meeting appointed Joseph A. Boucher to the position of sales manager.

THE AIR REDUCTION SALES Co., New York City, has consolidated its executive offices at 120 Broadway and 160 Fifth Ave., which will now be located at 342 Madison Ave., New York City.

E. M. RHOADS, president and treasurer of the Sanitary Co. of America, has disposed of his controlling interest in that company and resigned from the management on Jan. 5, 1923. A number of the former officers of the Sanitary Co. of America, together with factory superintendents, etc., are associated in the building of a soil pipe plant at Boyertown, Pa., to be known as the Eastern Foundry Co. The personnel of this latter company is as follows: E. M. Rhoads, president; B. W. Frederick, vice-president; Grant P. Bechtel, secretary and assistant treasurer; Daniel G. Burkert, assistant secretary and purchasing agent, and Harry R. Trout, general superintendent.

TOCH BROTHERS have moved their executive and sales offices to 110 East 42nd St., New York.

THE COMBUSTION ENGINEERING CORP., New York, announces the acquisition of the Quinn Oil Burner & Torch Co. W. R. Quinn, former president of the Quinn Oil Burner & Torch Co., has become associated with the Combustion Engineering Corp. as manager of its fuel oil department.

THE CHAIN BELT Co., Milwaukee, Wis., announces the appointment of Fitch S. Bosworth as manager of the Chicago office, effective Jan. 1, 1923. Mr. Bosworth has been in charge of the Chain Belt Co.'s St. Louis office for the last 3 years and has specialized on chain and conveying engineering problems. With him will be associated Raymond X. Raymond, who for several years has been connected with the export sales department in Milwaukee. Thomas F. Scannell, formerly of the Chicago office, has been placed in charge of the St. Louis office.

THE JERSEY CITY WELDING SHOP of the Metal & Thermit Corp., in addition to its present facilities for undertaking Thermit welding repairs, has also been recently equipped for making welds on lighter sections by means of the oxy-acetylene and electric processes. This service will be of particular value in cases where large production work is desired. Work can be called for and delivered by truck. This policy of equipping welding shops with the additional welding facilities, as described above, will later be extended to the other welding plants.

THE OXWELD ACETYLENE Co., Newark, N. J., announces that its Western department, formerly located at 1077 Mission St., San Francisco, has recently moved to larger quarters in the same block. Leo Romney is manager.

THE DODGE SALES & ENGINEERING Co., Mishawaka, Ind., which has for the past 8 years been operating as the selling subsidiary of the Dodge Manufacturing Co. and Dodge Steel Pulley Corporation, has now been consolidated with the parent company, Dodge Manufacturing Corp., which was organized and began business last July. The Dodge Manufacturing Corp. at that time took over the two long-established manufacturing concerns, Dodge Manufacturing Co., organized in 1880 and Dodge Steel Pulley Corp., organized in 1917 as the successor of the Oneida Steel Pulley Co., which began the manufacture of steel pulleys in 1900. Since July, 1922, the manufacture of Dodge, Oneida and Keystone power transmission appliances and Dodge heavy oil engines has been conducted by the Dodge Manufacturing Corp. The distribution of Dodge products, which has heretofore been done under the name of the Dodge Sales & Engineering Co., will hereafter be conducted by the sales department of the Dodge Manufacturing Corp., with Duncan J. Campbell, general sales manager, in charge, and John A. Beynon assistant general sales manager.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va., May 7 to 9.

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O., April 28 to May 4.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 8 and 9, 1923.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace, New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

CHEMICAL & METALLURGICAL ENGINEERING

Volume 28 New York, February 7, 1923 Number 6

Bootlegging Is Developing The Fine Art of Smuggling

CONTEMPORARY philosophers, particularly those of a thirsty inclination, have often said that prohibition is responsible for making the United States a nation of criminals. In view of the widespread violation of the Eighteenth Amendment, we have never been disposed to controvert their argument. Recently, however, a prominent manufacturer of fine chemicals has called our attention to another phase of the prohibition problem that seems to carry with it a serious menace to certain of our chemical industries.

When an industry grows to tremendous proportions, byproducts often become sources of unexpected profit. Now, as bootlegging has gradually reached the stage of big business, it is perhaps natural that it should develop some profitable sidelines. One of these is smuggling, and along the coast lines and international borders an illicit traffic of no mean proportions has been developed within the past few years. It was recently stated in Congress, on no less authority than that of the State Department, that from the little islands of the Bahamas alone over 1,200,000 gallons of liquor is annually smuggled into the United States. As this traffic became established on such a large scale, and with comparative ease, it was not unnatural that the bootlegger should reach out for a profitable expansion of his business. With the same equipment that was required to bring in 50 or 100 cases of a material as bulky as liquor, he found that he could handle thousands of dollars worth of expensive drugs, pharmaceuticals or fine perfumes. To be sure, the risk was a little greater, the penalties considerably more severe, but probably these dangers served merely to add zest to the bootlegger's game.

Our manufacturing friend tells us that as a result of this diversion the country is being flooded with smuggled drugs—salvarsan being a particularly prominent example. Much the same condition also exists in the case of high-priced synthetics used by the perfumers and extract manufacturers. And, too, the dope and narcotic traffic continues without abatement.

That these clandestine importations threaten the very existence of American industries is obvious. Just what the domestic manufacturer can do to prevent them, however, is not so clear. He can insist on better enforcement, and can and should aid the federal authorities in ferreting out information regarding the origin and source of material believed to have been illegally imported. He should not lose sight of the fact, too, that under section 516 of the new tariff law the American producer for the first time in history has been given the privilege of appealing to the customs authorities for information regarding classification and appraisement of competitive imported products. This is one very definite way in which the attention of the government can be centered on imports of questionable origin. In time, other procedures will doubtless suggest themselves, but it behooves the chemical industries to take immediate steps to put an end to this disastrous phase of the bootlegger's activity.

Pearly Gates For the Unregenerate

IN the last October number of our French contemporary *Chimie et Industrie*, MM. CLÉMENT and REVIÈRE announce their achievement of synthetic mother-of-pearl. The pearl oyster, it appears, secretes an albumenoid material called "conchyoline," which contains calcium carbonate and water, and the authors found that when calcium carbonate is precipitated in a colloidal medium under certain conditions, it forms a network of particles which displays the optical phenomena of a grating. Salts of other metals show similar but less pleasing effects owing apparently to the finer grain of the calcium carbonate.

We confess to a sense of shock about this invention. We didn't mind the corrugated domestic rainbows brought out on so-called Tiffany glass years ago. But this is different. We went to Sunday School with diligence and learned our lessons to the end that we might eventually march in triumph through gates of just such pearly splendor, get an equipment of wings and a harp, and proceed to enjoy ourselves with a definite quality of distinction. Now along come these two Frenchmen with their precipitated calcium carbonate, and before we know it some movie magnate from Hollywood who never went to Sunday School will set up a "palatial residence" across the way, and in front of it will be the very pearly gates of our young desire—and no brimstone pit at the left entrance for our dearest enemies. It's too bad.

Beyond the Control Of the Directors

AT THE general meeting of the stockholders of the Magadi Soda Co., Ltd., held in London on Dec. 11 last, S. SAMUEL, the chairman of the board, said that "the very unsatisfactory position of the company had been brought about by causes beyond the control of the directors. Production had been hindered throughout by the failing of machinery and the fixing of the rate of exchange at 2 shillings to the rupee."

This brings up a very interesting question. Was the failure of the machinery wholly beyond the control of the directors? We admit the rate of exchange was. Suppose the accounts had not been properly kept and at the annual meeting they would have been unable to

tell what their assets and liabilities were. Would that have been "beyond the control of the directors"? It would not, and yet directors are not chosen because they are expert accountants. Suppose they had neglected to make sales, although there was a good market. They would have been to blame, and yet they were not all chosen because they were alkali salesmen. Then why was it beyond their control if the machinery they bought was improperly designed or improperly chosen? The decision to purchase certain equipment is just as much a part of their business as is keeping accounts and selling their product.

Later in the report we read that "the defects of the new bucket-dredger which had been sent to Magadi had now been made good and the dredger had been restarted; in a few weeks there would be a minimum production of soda at the rate of 100,000 tons a year." Why wouldn't the bucket-dredger work when it was set up? Evidently because it was improperly designed for the work in hand. Maybe a member of the board who doesn't know anything of technology bought it from an officer of a machinery company who knows nothing of soda production.

The chairman of the board made an error that is even more common in this country than it is in England—namely, that ignorance of technology is excusable among the directors of a manufacturing corporation. In point of fact the board of a corporation is a unit. No one man can know everything. To have a consultant on call will not solve the problem, because those who are not properly informed do not know when to send for him. It is just as important to have a competent technologist among their number, to avoid such mistakes as this, as it is to have men who can read a balance sheet. Then these mistakes will not be "beyond the power" of directors. The condition will be within their control and the errors will be avoided.

Growing More And More Helpless

CONGRESSMAN RAINEY of Illinois declares that there are now on the federal payroll and on state and municipal payrolls, and pensioners and others who are maintained by taxes, about 3,350,000 men and women. That would indicate that 15,000,000 persons in the United States live on taxes collected from their fellow citizens. There are only 30,000,000 of us engaged in productive labor. Therefore every two persons so engaged support besides their own families at least one man, woman or child by the taxes they pay. If they don't pay it in taxes they pay it in rents or other living expenses.

In 1897 there were 167 federal deputies, agents, etc.; in 1907 there were 3,000, and in 1922 there were over 30,000 federal deputies, agents and inspectors on the government payroll. Within the last 65 years federal taxes have increased from 46 cents to $30 per capita. The latest plan for adding to the tax burden is to collect the British debt on the best possible terms and then blow in the whole four or five billions on a soldiers' bonus.

What are we going to do about it?

No matter what we think as individuals, these plans may go through. Politicians respond to what they think is public opinion, and this noise to which they are obedient does not contain as yet any intimation that taxes raise rents and living expenses. The noise demands that commissioners be appointed to examine into and control nearly everything there is. The politicians obey.

When this government was organized there was THOMAS JEFFERSON, who held that the people should manage their own affairs and that we should have as little government as possible. ALEXANDER HAMILTON, on the other hand, upheld the idea of a strong central government to control affairs. Both were philosophers and thoughtful men. We have discarded JEFFERSON and followed HAMILTON, which might have been well enough if we had only kept our wits about us. But we followed thoughtlessly. We demanded government control of anything and everything until now it has become a burden. As an example, the Bureau of Indian Affairs supports between 5,000 and 6,000 employees to look after 200,000 Indians, and the Indians are suffering from lack of intelligent and conscientious attention. Nevertheless this same bureau asks for an appropriation of $13,000,000 for the coming year. The government is fairly choked with just such abnormal growths on various parts of its system.

Some day the pendulum is bound to swing back for the same reason that a rocket that goes up must come down. We as a people shall grow tired of the infernal cost of so much government. The noise will say so, and the politicians will proceed to cut and slash. They will not do so intelligently, because it is the habit of politicians to address themselves to window-dressing rather than to look ahead beyond the next election. So we would better prepare to manage our own affairs without government support. This simpler and less expensive and less helpful and less meddlesome government may be slow in coming, but it is bound to arrive some day. It will be wise for us to consider our situation beforehand.

Smoke Damage And Chimney Height

ON page 1220 of our issue of Dec. 20, 1922, we published a brief abstract of a decision on a smoke suit dating back to 1917, in which the plaintiff was given a judgment for some damage incurred while the flue system of the St. Louis Smelting & Refining Co. was under reconstruction. Unfortunately, however, the caption of the note stated that "Doubling Height of Smelter Stack Causes Fume Damage."

Our readers will doubtless recognize in this one of the slips and errors which happen to any organization of mere humans. Those interested in smoke have followed our very full accounts appearing during the last 5 years of investigations on that problem. These researches have established so clearly as to be beyond reasonable doubt that no crop damage results from SO_2 fumigation except when definitely known concentrations are exceeded for definitely known times and under optimum conditions of sunlight and humidity. In other words, sulphur is successfully eliminated from a smelter system by correct dilution of the flue gases into the surrounding atmosphere before the smoke stream touches the ground. It is self-evident that this dilution increases with the temperature of the gases and the elevation at which they are discharged.

Therefore the possibility that crop damage could be increased by doubling the height of a stack—other conditions remaining the same—is so remote that those cognizant of the smoke situation would unconsciously appraise our headline as an error.

The Raging Battle Of the Oil Titans

THE greatest legal struggle in the history of American industry is now going on in an effort to decide what is what and who is who in the oil-cracking business. Hundreds of millions of dollars are involved, a money value with which there are few comparisons. Tales of Captain KIDD'S treasure chests or even stories of the fortunes of modern bootleggers would have to be put through at least a seven-stage radio amplifier to be heard in this battle of the oil Titans. We are now producing annually about six billion gallons of gasoline in this country. Imagine the great, green depth of Niagara Falls roaring away for about 45 minutes and one may perhaps visualize our annual gasoline production. The proportion of "cracked" to straight-run gasoline made from the crudes is rapidly approaching a one-to-one ratio. Fuel oil passed through an efficient cracking plant is enhanced in value about 6 cents per gallon.

Why the big fuss? Simply because the elements of oil cracking, heavier hydrocarbons to lighter ones, were discovered when present-day graybeards were living in "The Days of Real Sport" with Skinnay and the Pup. Coupled with the general situation is a crippled, sadly underpaid Patent Office. That gasoline was produced in substantial quantities by the old-fashioned cracking processes was reported by Prof. C. F. CHANDLER away back in the pre-bicycle age. And we moderns know too that a very large part of what is now included in the gasoline or motor fuel fraction was formerly run into the kerosene fraction. True the yield of gasoline is increased and its quality is improved by distilling or cracking under pressure, but KREY, DEWAR and REDWOOD and others developed processes of this sort back in the lower Pleistocene. And now, too, interested people are discovering that fossil apparatus discovered in the chalk cliffs of Bayonne and other points can be operated so as to produce gasoline. Furthermore, it is rumored that some of the curious markings on papyri carefully preserved at the Patent Office have been made to blossom, like Japanese pith flowers, into working drawings of gasoline-cracking apparatus.

To one who is not a Jack-be-nimble lawyer, and not gazing into a crystal, several things appear to stand out as real. Somebody must have had to dynamite away a deal of conservatism and start the thing going—show that marketable cracked gasoline could be manufactured in a big American way, and at a cozy profit. It seems to us that this was WILLIAM M. BURTON. To a casual reader of the daily papers it appears that Burton stills have been known to blow up when you didn't want them to. We understand that one of the big troubles has been the formation or carbon or coke. We are told that many forms of apparatus have been built, some with the tubes running north and others west, but the carbon deposits just the same. Then somebody discovered that if the oil is heated hot enough and then passed into a receiver, insulated so not to lose the heat, the cracking proceeds for some time and most of the coke forms and is deposited in this insulated chamber, removed from the heating surfaces. It seems that this principle is made use of by CROSS and by DUBBS.

The legal struggle has settled down to four or five major contestants, each with an impressive rosary of patents. In the meantime, conditions in the industry have become such that it is practically imperative for a refiner to "crack" or be cracked. The freedom of the whole industry is, to a large degree, at stake. If the courts should hold that one or two of the earlier live patents, now in litigation, are basic, then the whole industry will have to pay tribute. Ten cents per barrel of stock treated is the royalty proposed by one concern.

It seems likely, at least we hope, that out of this great polygonal debate will come a clarification of our patent law, the establishment of new precedents as to what is patentable matter. We have noted the recent decision, after appeal, in the case of the Saybolt patents for absorbing gasoline vapor under pressure from natural gas, that the said process and patents merely set forth certain simple and widely understood principles of physics. How long will American industries tolerate \$2,000 patent examiners to grind out confusion for the \$15,000 judges, to the delectation of the \$50,000 lawyers and the despair of those who pay for it all?

Awaiting Operating Data On the Colloid Mill

ABOUT 30 months ago the first article on the colloid mill was published by its inventor, Dr. HERMAN PLAUSON. From this and subsequent articles we have built up our present conception of a grinding mechanism that has attracted world-wide attention. The idea seems to be to subject a substance suspended in liquid to the extreme disintegrative action of teeth set on a cylinder which rotates at high speed and drives the particles against stationary teeth set on a concentric shell. The cylinder is designed to operate at very high speed, claims having been made of an attained peripheral speed of 650 ft. per second and a possible speed of over 3,000 ft. per second. This is the so-called impact type mill, which, together with the friction type mill, was described in detail in our issue for Jan. 10.

There seems nothing impossible in the conception of such disintegration. To anyone who has worked with dye pastes or other substances where fine subdivision is essential, a mechanical disintegrator is conceivable. But the stumbling blocks in the way of complete optimism regarding its utility are incidental to the terrific speed that is necessary. First, there is the wear and tear of heavy work at high speed. Of course in a machine like the Sharples supercentrifugal we have speeds which the colloid mill probably would not reach; but the supercentrifugal has a relatively light cylinder rotating in air, while the colloid mill must have a heavier cylinder operating in a liquid. If the mill is used to make actual or near colloidal solutions, the liquid would often be viscous. As a matter of fact, in terms of 1,000 r.p.m., any liquid is viscous. Then the mechanical details of construction of such a mill on a commercial scale offer a formidable problem. Of course it is not impossible, but it presents such difficulty as to make commercial success almost a greater achievement than the invention itself. Finally, after the mill has been made a mechanical possibility, the high operating cost for power and the replacement cost of worn parts due to heavy wear and tear present operating difficulties that suggest a distinct economic handicap.

So far there are no existing data on the operation of the mill and they are being awaited with interest. The difficulties outlined here are not regarded as insuperable; they merely indicate the very definite engineering problem that must be solved before the mill can be a success.

tell what their assets and liabilities were. Would that have been "beyond the control of the directors"? It would not, and yet directors are not chosen because they are expert accountants. Suppose they had neglected to make sales, although there was a good market. They would have been to blame, and yet they were not all chosen because they were alkali salesmen. Then why was it beyond their control if the machinery they bought was improperly designed or improperly chosen? The decision to purchase certain equipment is just as much a part of their business as is keeping accounts and selling their product.

Later in the report we read that "the defects of the new bucket-dredger which had been sent to Magadi had now been made good and the dredger had been restarted; in a few weeks there would be a minimum production of soda at the rate of 100,000 tons a year." A Protest

To the Editor of Chemical & Metallurgical Engineering

SIR:—The American nation is, I am told, specially courteous to women. I take it therefore for granted that you will publish in full this letter.

Friends have put before me pages 776 and 777 of your journal for Oct. 18, 1922, and I am assured that your paper has a wide circulation among American engineers and chemists. To my great astonishment my cartoon which appeared in the *Fliegende Blätter* has been reprinted without my permission and has been explained at the same time in a way which excels the misrepresentations disseminated during the world war in the Northcliffe and other press of the former enemies of Germany. The following explanation of my satirical cartoon may suffice:

The *Fliegende Blätter* is an entirely non-political paper, which ridicules and condemns human weakness of every kind. Vox populi means the voice and judgment of the masses in *all* countries of the world. Nowadays people are generally not guided by leaders of a supernormal intellect, intelligence and very high qualification, but in the first instance the mind of the masses is dependent on the press, the influence of which is increasing everywhere.

The fallacy of human leaders is proved by the downfall of Woodrow Wilson in your country and Lloyd George in England, not to speak of the German leaders in 1914 to 1918. The press leading the masses is imbued with phrases and catchwords. The owners and governors of the press are rarely guided by ideals, but mostly by egoistic thoughts. The masses are like a flock of sheep (*Hammelherde*), who follow the guide-wether (*Leithammel*). In a great many countries the "Leithammel" of the press are "wolves in sheep's clothing," who feed the sheep with phrases and catchwords. This, my general impression of *all* countries, was pictured in my cartoon. I regret that such long interpretation is necessary to prove that the author of your article has not understood the proper meaning of the word "vox populi" and of my cartoon and that a journal of your position and reputation has published such wrong judgment of my country without consideration of the true state of affairs in *all* countries.

KÄTHE OLSHAUSEN-SCHÖNBERGER.

Munich, Germany.

EDITOR'S NOTE: We gladly grant space for our correspondent's explanation. Our interpretation of the cartoon still seems particularly fitting to conditions in Germany, where the masses have been exploited by a few industrialists.

Numbering of Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is curious how variously a piece of writing can be viewed. Your editorial of Dec. 27 leaves one of your correspondents dizzy from your persiflage, while to some others of us it appears to be a sensible constructive review of the situation.

The question of numbering or codifying steels is of considerable importance. But if it is to be discussed intelligently, every proponent of a numbering system should start by stating quite definitely the purposes to be served by the system.

To my mind there are two main spheres of usefulness for a numbering system:

(1) A manufacturer who makes machine parts and purchases semi-finished steel bars, blooms, etc., of various grades and desires to give each grade of steel a designation so that it may be readily recognized and referred to, to the end that the correct steel shall be selected and used for each part to be manufactured.

(2) A designer wishes to use on his drawings a simple notation which shall show the kind of steel to be used for each part.

These two applications are to a certain extent overlapping and in practice will be subject to many minor variations and developments. They do, however, show the essential characteristics required of any useful system of designating steels. Both uses lead eventually to the purchasing agent, and in this fact lies the necessity that the numbering system to be really useful must be perfectly definite. Suppose that under a system applied to our No. 1 purpose, the stock of a given steel is running low and the stock clerk requisitions 100 bars 4 in. square by 10 ft. long of XYX steel. The designation XYX is sufficient and satisfactory if it enables the clerk in the purchasing department to fill out as a matter of simple routine a request for bids or an order which will indicate without further question the steel required. To my mind this can be done only by having the symbol XYX represent a complete and definite specification. A symbol which merely indicates the general proportions of the principal elements is useless to the purchasing agent. To place his order intelligently he must have an open-or-shut specification on which he can accept or reject without argument.

Similarly for our No. 2 purpose. To fulfill the designer's needs the designation on the drawing must leave no doubt as to the properties of the finished piece. These must be so clearly expressed that it becomes a routine matter to select the raw material and to choose the processes it is to undergo to give the desired results. Again the symbol designating the steel must lead to a complete specification.

It is evident that for semi-finished material (our purpose No. 1) the numbering will in most cases lead only to a specification as to chemical composition, while for finished parts (our purpose No. 2) the specification must usually cover physical properties with some indication as to the chemical composition, but in both cases the numbering to be of practical value must give a concrete, definite account of the steel it describes.

Studies on Graphite Crucibles

In order to investigate the crucible-making properties of American graphites as compared to foreign graphites, seven sets of crucibles, six to the set, were made by the Vesuvius Crucible Co., according to a formula furnished by the Ceramic station of the Bureau of Mines.

In arriving at this formula, the bond clays were varied and the Ceylon graphite kept constant. Crucibles made from the most promising mixes were tested in steel-melting practice at the Lockport, N. Y., plant of the Simonds Manufacturing Co. Some of the crucibles gave ten melts before failure, which is considered excellent practice.

Using the most promising mix of bond clays and graphite obtained in the above-mentioned tests, seven sets of crucibles were made up using seven different graphites and are now awaiting test. The graphites used were Ceylon, Madagascar, Alabama, New York, Montana, Texas and Canadian.

How "Asbestos-Protected Metal" Was Developed Commecially*

The Early Stages of Development and the Peculiar Problems Which Had to Be Solved Before the Product Became a Commercial Success—The Process of Manufacture—Some Still Unsolved Problems

BY J. H. YOUNG
Senior Industrial Fellow, Mellon Institute of Industrial Research, University of Pittsburgh, Pittsburgh, Pa.

THERE are two fundamental problems with which man has had to contend since time prehistoric. Man's first duty has been to provide food and his second to provide shelter. Accordingly, the general subject "building materials" is not one which is impressive by its newness; it is one which has been with us always and that always will remain. However, with the advent of the modern factory and chemical industry, there have come some novel phases of the subject which are of interest to the chemical engineer.

As a rule, the chemical engineer has busied himself with chemical processes and equipment and has given but little attention to the selection of the proper building materials to house his industry. This constructional task has been left to the architect; and although this specialist has conscientiously done his best and, as a rule, has made wise selections of his materials, his training does not fit him for meeting the many problems connected with the proper housing of the various and highly diversified chemical industries, without advice from those who should be peculiarly well qualified to render such aid—namely, the chemical engineers. In times past this advice has been neither sought nor offered. As one result, buildings containing much lead in their structures have been erected to house industries in which high concentrations of acetic acid prevail in the atmosphere. Concrete, copper, aluminum, zinc and steel —in fact, all building material—have limitations and have been used under conditions for which they are not adapted. Therefore the chemical engineer may quite profitably study the materials available for his buildings as well as those used in its equipment.

During the development and expansion of the steel industry corrugated steel sheets, either the so-called black-iron or the galvanized iron sheets, have come into very wide use as a roofing and siding material on industrial buildings. The comparatively short life of these sheets has led to the development of a number of useful roofing and siding materials for industrial buildings, each of which nevertheless leaves something to be desired. In other words, the perfect roofing and siding material is yet to be evolved. Among the comparatively new roofing and siding materials which have been developed is the so-called asbestos-protected metal and it is particularly with this product that this paper deals.

EARLY STORY OF ASBESTOS-PROTECTED METAL

The early history of many American industries teems with tales of struggles against great odds. The surviving manufacturers usually owe final success to the courage, faith and active optimism of a single individual who has never recognized defeat when he encountered it. Such has been the case with the asbestos-protected metal industry. Starting in 1905, at Canton, Mass., with an idea that a steel sheet could be protected from corrosion by dipping it in molten asphalt and then pressing a layer of asbestos felt on each side of the coated steel to protect the asphalt, H. H. Robertson stuck by his idea through thick and thin, and there was considerable thin until the present product was evolved.

As may readily be imagined, the original product was a failure, the asbestos felt rapidly washing from the sheet upon exposure and collecting in the roof gutters or on the ground. To overcome this difficulty, the asbestos felt was saturated with a waterproofing mixture, of which chinawood oil was the principal ingredient. The resultant product was considerable improvement over the original material and really gave pretty good service. However, the edges and ends of the steel sheet were unprotected, and this resulted in a weakness which was finally overcome by folding the felt over the edges of the steel.

Commercial success was not achieved until 1909, when the late Dr. E. T. Newsome developed new machinery which made it possible to manufacture a product consisting of a sheet steel core covered with asphalt and wrapped in asbestos felt saturated with a waterproofing agent. This product of 1909 won commercial success, but although it had sufficient merit to warrant its sale, it was considered to be a long way from perfection. It may be added, though, that there are a number of installations of this 1909 product which still are serviceable.

Recognizing that improvements were possible in its product, the manufacturing company adopted the policy, which has since been adhered to, of utilizing a part of its resources each year in development work. As a result of the researches carried out during the period 1909-1916, the present product was worked out and pro-

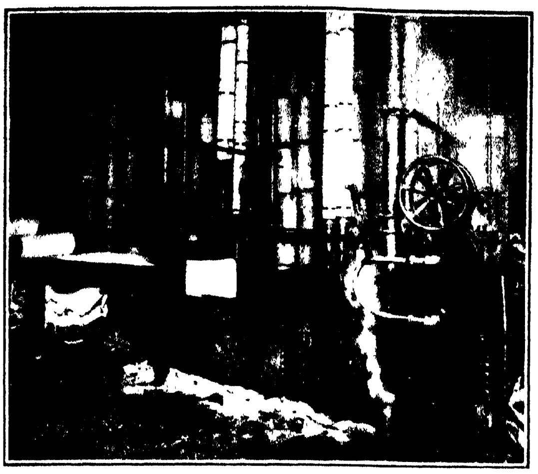
*Paper presented at the Richmond meeting of the American Institute of Chemical Engineers, Dec. 6-9, 1922.



SATURATING ASBESTOS FELT

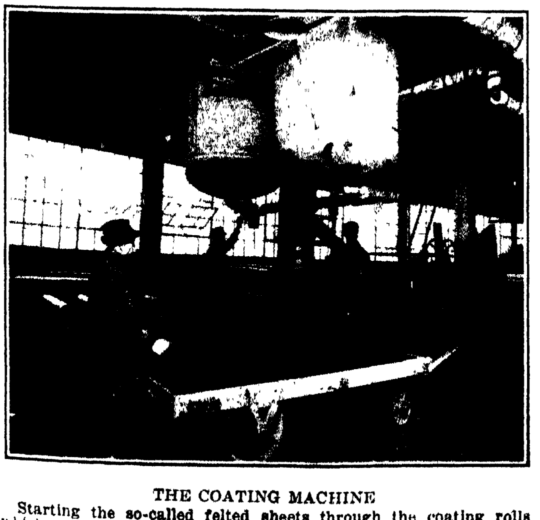
duced in 1916. This product differs from that of 1909 in that asphalt is used to saturate the asbestos felt and the felt layer itself is protected by a bituminous coating which retards the drying and hardening of the bituminous layers beneath, thus increasing greatly its weather-resisting properties.

The orignal asbestos-protected metal was made in Canton, Mass. In 1911 the company moved to Beaver Falls, Pa., and in 1916 the present factory at Ambridge, Pa., was occupied. Factories in Canada and England were then added.

What Is Required of Roofing and Siding Materials

Before taking up in detail the discussion of asbestos-protected metal, it is appropriate to present an opinion respecting the requisite essentials in the perfect roofing and siding material. When a roofing and siding material is referred to, there is meant the type represented, for instance, by corrugated galvanized iron which is used to cover the so-called skeleton type building.

It is believed that the perfect roofing and siding material, in order to meet various and complex requirements of roofing service, should have the following characteristics: (1) It should have strength; (2) it should be resistant to weathering; (3) it should be light in

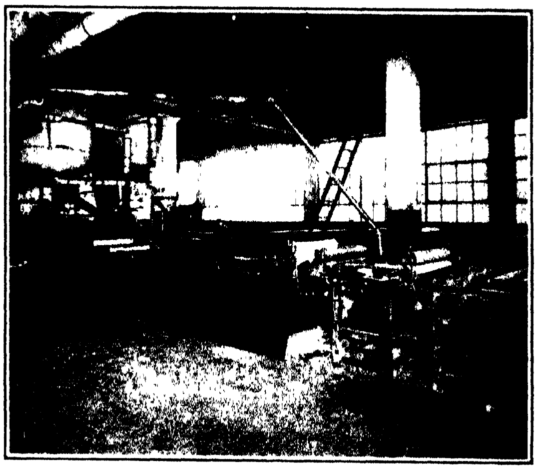


THE COATING MACHINE
Starting the so-called felted sheets through the coating rolls which put on the weatherproofing coat.

weight; (4) it should be adaptable to buildings of standard design; (5) it should have a low fire hazard; (6) it should have a low thermal conductivity; (7) it should be capable of conforming to any color scheme required; and finally (8) it should have a reasonable first cost and a low per year cost.

Since steel is the basis of asbestos-protected metal, the strength requirement is well taken care of. By choosing steel of the proper gage, it may be made to span successfully any purlin spacing ordinarily used. The weight of asbestos-protected metal is approximately 1.3 times the weight of galvanized iron. Being similar in form, strength and weight to ordinary corrugated steel roofing, it will span with a wide margin of safety all standard purlin spacings, and may be worked into flashings and other standard shapes. It is easily adaptable to the general run of mill buildings without the necessity of designing the buildings to meet any limitations of the roofing material.

In order to get a better idea of the durability of this product, it is necessary to describe the various protective coatings used over the steel and the methods of applying them. The first and most important bituminous coating is applied by pulling the clean steel sheet

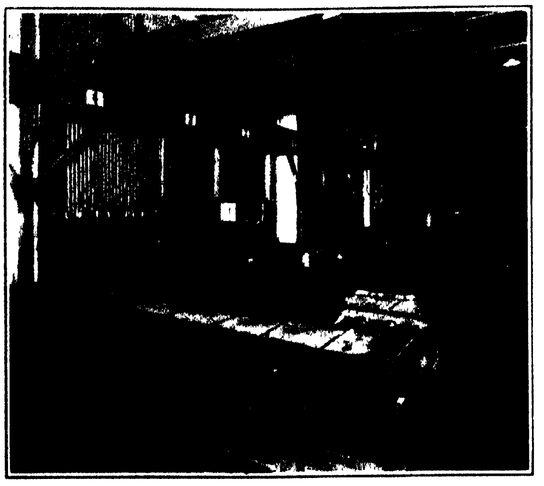


THE OTHER SIDE OF THE COATING MACHINE
Showing cooling tank for cooling the asphalt coating and the tank for applying the solution of cellulose thiocarbonate.

through a vat of the asphalt maintained at a temperature of 350 deg. F. The viscosity of the asphalt at this temperature is such that a uniform coating weighing about 16 lb. per square (100 sq.ft.) is put on the steel. As the coated steel emerges from this tank, asbestos felt, previously saturated with asphalt, is pressed on to both sides and folded around the edges of the steel, thus completely sealing it. The next operation consists of running the so-called felted sheets through coating rolls, which apply the top waterproofing coat. The coating rolls operate at a temperature of about 425 deg. F. The whole process is one in which no solvents are used, the asphalts being applied in a melted condition.

The asphalt used directly on the steel is an air-blown petroleum asphalt having a low susceptibility factor, being soft and adhesive at low temperatures, yet not flowing at temperatures reached on roofs, even in the tropics. It contains practically no mineral matter and is chemically quite inert, particularly toward acids and slightly less so toward alkalis.

The saturant for the asbestos felt is also an air-blown



FEEDING STEEL SHEETS INTO THE FELTING MACHINE

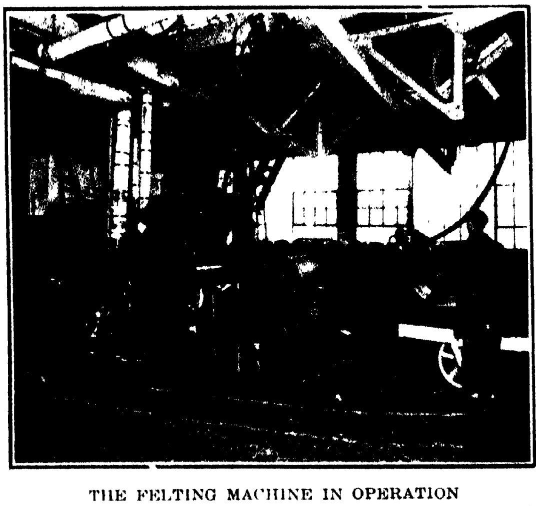
asphalt of the asphalt-base petroleum type, and it is also quite inert chemically.

The top or weather-proofing coating is a compounded bitumen, being of the so-called stearin pitch type. It is similar in composition to the best baking japan bases and withstands weathering conditions very well.

It is clear, then, that there are three layers, each of which is of bituminous composition and is of substantial thickness. The chemical nature of these compositions is such that they will resist a wide range of chemical conditions. Asphalt will resist the chemical action of a wider range of chemicals than any other commercial adhesive known at present. A study of the performance of the product under actual service conditions of all sorts and in all climates show that it is a relatively durable building material.

Fire Hazard and Corrosion

Regarding the fire hazard, since each square of metal has approximately 36 lb. of asphalt on it and since asphalt is combustible, there is a certain fire hazard involved in the use of the material. Where used on a roof, the hazard is of little consequence, because of the fact that burning embers and the like, falling on such a



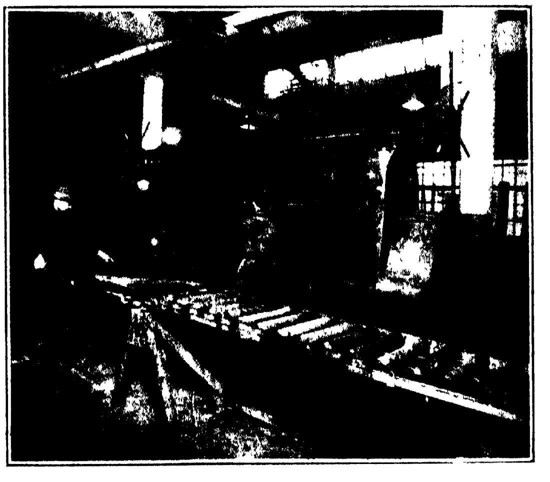
THE FELTING MACHINE IN OPERATION

The steel sheets travel through hot asphalt and upward through combining rolls which press asbestos felt onto both sides of the steel sheet and fold the edges of the felt around the steel, forming a continuous web.

roof, will fail to produce a spreading fire. In other words, the asphalt has such a low combustion rate that the heat is dissipated upward too rapidly to keep the film burning and the fire is localized at the spot where the ember falls. In case of a side wall a fair-sized fire at the base may ignite the coating, and the coating under favorable conditions will continue to burn upward until the roof is reached; but the damage done consists of the loss of the protection to the steel sheets, which may still give some service if painted.

While the fire hazard of a roofing and siding material is an important factor to be considered, it is interesting to note that the loss from so-called slow burning or corrosion is several times as large each year as the loss from fire. One gains much food for thought in looking over the long list of so-called fireproof buildings which have burned each year. Truly the fire hazard is important, but the corrosion hazard is of equal if not greater importance.

In general, it is quite important to have a roofing and siding material with a low thermal conductivity, because a building housed with such material is heated with less



THE CORRUGATING MACHINE

expense in the winter and is cooler in the summer and also because it transmits sound less readily, as a rule. Asphalt is among the very best non-conductors of heat, and it is safe to say that the material under consideration is as poor a conductor of heat as any material of equal thickness used for roofing and siding purposes. Its deficiency lies in the fact that it is not very thick; but in actual practice it compares very favorably with ¼ in. pine wood in so far as heat loss is concerned.

The Problem of Color

Coming now to the subject of painting or producing various color effects on or with it, it is confessed that, outside of dark colors, such as maroon, dark green and brown, it has been impossible to produce colors satisfactorily, either by painting or by incorporating pigments in its outside coating. White or light-colored drying oil paints or enamels, when used over bituminous surfaces, become discolored by dissolving the dark bituminous coating; then, too, the paint films tend to distort the underlying bituminous material, producing an effect commonly termed "alligatoring." If a priming coat of shellac or other similar gum is applied to a bituminous surface, a drying oil paint may then be put on without becoming discolored, but, upon exposure, cracking and

"alligatoring" take place. For interior finishes a fairly satisfactory result is obtained by the shellac priming-coat method, provided either a cold-water paint or a drying-oil paint is used over the shellac. A Manila copal spirit varnish may also be used as a priming coat. A cellulose nitrate lacquer has been developed in which alcohol is the principal component of the solvent. This lacquer is satisfactory as a priming material, and with aluminum or bronze powder it will produce a satisfactory light- and heat-reflecting finish that weathers fairly well, without cracking or distorting the coating. It may be seen that, although it is possible to produce several light color effects, they are all more or less of the makeshift variety. It is true, however, that on the vast majority of buildings of the type covered by similar materials dark colors are not objectionable; indeed, they are often preferred.

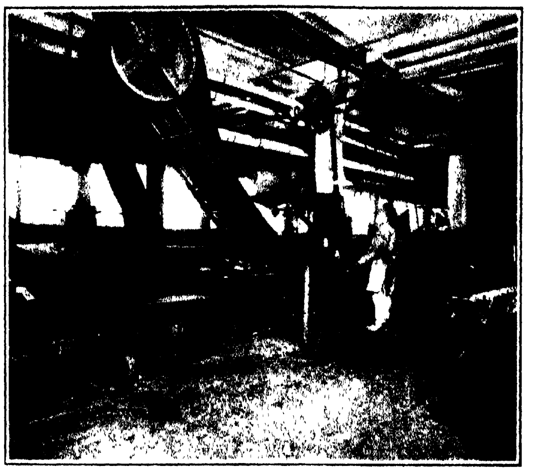
Taking up finally the factor of cost, it may be said that asbestos-protected metal compares very favorably in first cost and in per year costs with material used for the same purpose. Erected, it costs from one and one-half to two times as much as painted galvanized iron; but on a per year basis the cost will average very much below that of painted galvanized iron, when its low maintenance cost is considered.

Summarizing the characteristics of asbestos-protected metal, it may be stated that it is strong, durable, adaptable and light in weight, and has a fairly low thermal conductivity. It has a certain fire hazard, and is not capable of being painted satisfactorily with drying-oil paints. It has a relatively low first cost and a low per year cost.

Some Research Problems, Solved and Unsolved

In the development of any industry it is natural to expect a variety of problems to arise, and often they come from quarters least expected and at most inopportune times. One such problem appeared when the present type of asbestos-protected metal was first marketed. It was found that, even though a very high melting-point asphalt had been used as the top weatherproof coating, the sheets, when piled flat and shipped to southern and even northern points, would stick together firmly. All sorts of fine powders were used as surfacing materials to attempt to eliminate the difficulty, but with little success. The research finally developed a viscose solution which could be used to coat the sheets, and this worked successfully. As you are reminded, viscose is the term applied to solutions of cellulose thiocarbonate. Heretofore, these solutions have been used largely to produce artificial silk. To prepare viscose, cellulose in the form of cotton or wood pulp is treated with caustic soda and carbon bisulphide under proper conditions to form a water-soluble compound. Viscose, when heated or treated with salt or acid solutions, decomposes to form a so-called regenerated cellulose. This regenerated cellulose has lost its fibrous structure and is clear.

By running sheets through solutions of viscose, they become coated therewith. The sheets then are dried at a temperature of about 120 deg. F., which results in the decomposition of the viscose to form cellulose hydrate. Inasmuch as the viscose on the sheets is in the form of a thin film, the regenrated cellulose hydrate produced is in the form of a thin colorless film, which completely covers the surface of the asphalt. This film prevents contact of bituminous surfaces where the sheets are piled and, as a result, the sheets do not stick together.



CUTTING THE CONTINUOUS WEB INTO INDIVIDUAL SHEETS

Another problem which has received quite a little research attention has been the fire hazard of the product. This problem has finally been solved and the product has been accepted as equal to steel sheets as a fire risk in factories by insurance companies interested in fire risks of factory buildings. This result has been obtained by using asphalt containing hexachlorinated naphthalene as the saturant for the asbestos felt. It is found that, when this procedure has been followed and the sheet is exposed to a fire, the non-combustible vapors of the chlorinated naphthalene dilute the vapors of the asphalt to such an extent that the whole will not support combustion and consequently a fire is localized in so far as the sheets are concerned.

There is in addition the problem of painting bituminous surfaces, and, as has been pointed out, its solution is not yet at hand. One very interesting development has been that of coating such surfaces with various metals to form adherent and coherent films. This may be accomplished either by depositing a thin layer of metal on the surface of the asphalt electrolytically or by spraying molten metal thereon. Although this work is very much in the developmental stage, hopes are entertained for its successful future. The product of this procedure may be varied so as to meet different chemical conditions—for example, the lead-coated product will undoubtedly give excellent service under conditions in which oxides of sulphur are the corrosive agents. The zinc-coated product is of pleasing appearance, and any of the metallized surfaces may be painted over satisfactorily with any drying-oil paint. Such products are easily handled, stored and shipped, and are admirably adapted to tropical use. Another interesting product results from the use of granulated slate or minerals of different colors as an outside surfacing material to produce different color effects.

In conclusion, emphasis is put on the fact that the future development of industries is going to be more and more along chemical lines. In fact, the large manufacturing centers are becoming large chemical laboratories. The building materials of the future must successfully withstand these widely various chemical conditions and the development of such building materials is a problem of prime importance to the chemical engineer. It is hoped therefore that this paper will serve to stimulate his interest in the general subject.

How Can Financiers Prevent Industrial Overexpansion?

The Closer Co-operation of the Engineer and the Financial Man Is Suggested as a Practical Solution to This Problem

BY IVAR J. MOLTKE-HANSEN
Consulting Engineer, Brussels, Belgium

THE enormous development of the world's productive capacity in many chemical and electrochemical industries spells ruin to a great many undertakings and heavy losses to banks and shareholders. Is anybody responsible for this result? Who gave the starting signal for this wild rush of capital investment in these special lines? Of course, these industries are not the only ones to suffer from an overdevelopment after the war—for instance, in shipping one sees a similar overproduction of carrying capacity.

The common reasons of these great efforts are easily established and universally familiar: the war, the call for independence of each country or group of countries in the production of important commodities and finally much easily earned money, which called for investment. Yet ought not a great deal of this investment in impossible enterprises to have been avoided? I do not now deal with imperfect construction in certain of these war-time industries, nor with the recklessness in placing contracts for construction, which led to absurd wages for manual labor in many instances. What I want to get at is the fundamental relationship among bankers, promoters of industrial schemes and the engineering fraternity.

THE OLD CRY, "LACK OF TECHNICAL CONTACT"

It appears that this all-important relationship is very casual and has been very little cultivated in most countries till now, with a few exceptions. Bankers have as a rule very little insight into the chemical and allied industries and can hardly be expected to have this special knowledge. Promoters are too often without any special practice and knowledge of actual working conditions in the industries which they propose to establish and still less in their commercial aspects. But even when such knowledge exists the interests of promoters lead to an overemphasis of the optimistic sides of a proposed undertaking. The neutral and well-informed body of college and university professors and first-rate consulting engineers is either not called in at all or only too late and with a very restricted field of action. They are perhaps requested to express themselves on the strictly technical aspect or in a case of arbitration between a company and its technical leaders or advisers and in cases of patent questions and the like.

But the evil lies, in my opinion, at the very root of things. There is insufficient control at the very beginning or even before the beginning of *new industries*. Banking concerns, interested in company promotion or in lending money to industries, ought to have a much more thorough grasp on the whole situation than is now generally the case before committing themselves to industrial schemes. I should not have raised these questions merely to criticise existing conditions if I did not think there was a remedy for the evil. The salvation lies in a competent engineering department on logical and well-defined lines in every banking concern dealing with promotion work. Here and there one may hear of advisory engineers being appointed by one or the other bank. But comparatively seldom is the position of considerable importance.

Of all the various engineering departments of commercial banks which have come to my notice, there is one in a big Belgian bank which seems nearly perfection. I am not entitled to make its organization known publicly, but may say that it corresponds to the technical department of a big industrial enterprise. An adequate, well-equipped personnel under an experienced manager is able to cover those fields in which the bank is interested. An adequate technical library with scientific and technical periodicals and other branches of service necessary to a proper investigation of technological projects has also been established. The industrial clients of the bank are carefully watched as long as the bank takes an interest in them. The technical and financial control is serious and concerns itself with no other intention than to secure the safe development into fuller independence of the concerns in question, the degree of patronage being graded according to the needs of each case individually. The financial management of the bank is very well satisfied with the operation of its technical department, which after a short time became self-supporting through a system of modest working charges on services rendered to the various industries dependent on it.

TANGIBLE RESULTS OF A REAL SYSTEM

Such an organization secures fair treatment all around. Promoters will have confidence in submitting their propositions to such an impartial body; investors will know that an invitation to subscribe to a new company, whose working plans have been approved by his bank's technical service, offers the maximum safety.

The bank management will feel that no diversity of interests exists between the technical report of its own engineers and the policy of the bank and finally that the bank enters into no engagement with shut eyes as to what the undertaking may ultimately lead to in regard to capital outlay. The sad results in many countries of the war and post-war activity in promotion or extensions prove too well that in this field ignorance is not bliss. Any bank adopting the policy of full technical and commercial research of any industrial proposition put before it by its trained staff of experts will certainly in the end find that knowledge is power.

A conversation I had with my late friend Prof. Joseph W. Richards in September, 1921, on these questions made me believe that also in America things might be improved in this respect: the important and neglected rational relationship between the engineer and the banker. And to sum up my impressions and the experiences which have come to my knowledge: Much of the financial disaster from overproduction capacity after the war might have been avoided, had the banks and the financiers had at their disposal a well-established, technical service forming an integral part of their business outfit, somewhat on the lines indicated in the Belgian bank.

Drastic examples may be called in to witness the truth of this observation, which on reflection may seem so obvious to many as to be compared with the famous egg of Columbus. Yet it is one thing to admit the truth of a statement, another to conquer the inertia of long-established neglect and reliance on the rule-of-thumb methods. **The vital need of the hour calls for more exact businesslike and scientific treatment of the problems of the right relationship among capital, industrial initiative and engineering.**

The Resolution of Petroleum Emulsions

By Harold V. Dodd
Department of Petroleum and Gas, California State Mining Bureau, Taft, Calif.

The factors controlling the stability of emulsions in general have been thoroughly studied during the last 20 years, and the results of these studies were admirably presented and reviewed in some recent articles.[1] In this paper, therefore, the discussion of the theory of emulsification will be very brief.

Substances Soluble in Both Phases Are Found to Be Effective Agents for Breaking Down Crude Oil Emulsions, Providing Very Small Amounts of Acid Such as Sulphuric Are Also Introduced. The Mutually Soluble Substances, of Which Phenol Proved the Most Satisfactory of Those Tested, Conveys the Acid Through the Enveloping Oil to the Dispersed Water. It Has Also Been Found Advantageous to Use a Certain Amount of Heat During the Reaction

The Two Classes of Emulsifying Agents

A stable emulsion between two immiscible liquids is possible only in the presence of a third substance, the emulsifying agent, which collects at the interface and forms there a coherent film. There are two kinds of emulsifying agents—namely, those that are apparently soluble in one phase of the emulsion, and those that are insoluble. Investigation has shown that the apparently soluble emulsifying agents are actually colloids. The insoluble emulsifying agents are finely divided solids that have the property of collecting at the interface between the two liquids.

The only difference in the behavior of the two classes of emulsifying agents is that the colloids lower the interfacial tension, and it is generally supposed that the insoluble emulsifying agents do not. Lowering of interfacial tension undoubtedly promotes emulsification, but is not essential. The essential property of an emulsifying agent is its tendency to collect at the interface and form a coherent film, which prevents coalescence of the globules of the dispersed phase. If the emulsifying agent is water-soluble (a hydrophile colloid), or is more readily wet by water than by oil, the aqueous phase will be external; if it is oil-soluble (a hydrophobe colloid), or is more readily wet by oil, the oil phase will be external.

It has been claimed that ions adsorbed upon the globules of the dispersed phase will act as emulsifying agents, but there seems to be no satisfactory evidence that a true emulsion has ever been produced without the presence of a solid or colloidal emulsifying agent. There is no doubt, however, that the static charge on the globules of the dispersed phase, whether due to ion adsorption or to other causes that are not thoroughly understood, often increases the stability of an emulsion to a considerable extent.

The Emulsifying Agent in Petroleum

All crude petroleum emulsions are of the water-in-oil type, and we, therefore, know that the emulsifying agent must be some oil-soluble colloid, or some finely divided, insoluble solid that is more readily wet by oil than by water. Crude petroleum contains heavy hydrocarbons, such as asphalt, asphaltenes, etc., which are probably present in colloidal solution and could reasonably be expected to act as emulsifying agents.

Sherrick[2] suggests the importance of these asphalt-like bodies in the formation of petroleum emulsions, but since not all asphalt base oils emulsify easily, he thinks these colloidal substances are not, alone, effective as emulsifying agents, but must first be adsorbed upon hydrated earthy material, which is thus changed from a water-soluble to an oil-soluble colloid. This does not seem probable, because the conditions cited by him as favorable for the formation of such a colloid are not likely to have been of wide occurrence, and also because many emulsions contain little or no earthy material.

Furthermore, such an assumption is not necessary—the nature of the solution of the asphalt-like bodies in the crude oil probably depends upon the ratio of light fractions to lubricating fractions, and consequently the tendency to emulsify should be expected to vary; as the dispersion approaches that of true solution the tendency to emulsify should be expected to decrease. In every case that has come to the writer's attention, dilution with gasoline has made the emulsion more difficult to break. This indicates that the degree of dispersion of the asphalt-like bodies is more favorable for emulsification in light fractions than in heavy.

Asphalt in Oil-Field Emulsions

To test the effectiveness of asphalt as an emulsifying agent, the writer prepared some emulsions of distilled water dispersed in gasoline solutions of asphalt of various concentrations. The asphalt used was a refined product sold by the Standard Oil Co. of California under the name of "asphaltum cement." The emulsions were prepared by placing 50 cc. of water and 100 cc. of asphalt solution in 500-cc. graduated cylinders and agitating for 2 minutes by means of a 1½-in. propeller revolving at 3,500 r.p.m. When the concentration of asphalt in gasoline was 0.05 per cent by weight, no emulsion was produced; when the concentration was 0.1 per cent, 20 cc. of water was emulsified; when the concentration was 0.2 per cent or more, all of the water was emulsified.

These emulsions settled to the bottom of the excess gasoline within a short time and formed a compact, brown mass. They stood in the laboratory for 3 weeks, and at the end of that time none of them showed any tendency to break. Their extreme stability was shown by the fact that when a 25-cc. sample was shaken with 75 cc. of clean gasoline and the mixture centrifuged for 5 minutes, the same compact emulsion, slightly lighter in color, was thrown down instead of water. This procedure was repeated several times on the same sample with no results other than some change in color. An emulsion similar in appearance and similar in reaction to this test was obtained from an oil-field emulsion by diluting with gasoline and centrifuging.

Crude petroleum is said to contain traces of saponifiable organic acids. If this is a fact, it is reasonable

[1] Emulsification Symposium: *J. Ind. Eng. Chem.*, vol. 13 (1921), pp. 1008-1017, 1116-1123.

[2] *J. Ind. Eng. Chem.*, vol. 12 (1920), p. 133; vol. 13 (1921), p. 1010.

to expect oil-soluble soaps, which might act as emulsifying agents, but the amount of these would be so small, if present at all, that they may be neglected.

It is quite apparent that asphalt-like bodies, under certain conditions of solution, are very effective emulsifying agents. Since they are present in considerable amounts in all Western crude oil, it is safe to assume that they are responsible for the oil-field emulsions.

Breaking Emulsions Chemically

There are two antagonistic forces at the interface between the phases of an emulsion—namely, (1) surface tension, which tends to cause coalescence, and (2) the coherence of the film of emulsifying agent, which tends to resist coalescence. The stability of an emulsion depends upon the relative magnitudes of these opposing forces. If the coherence of the film of emulsifying agent is so great that surface tension is unable to rupture it, the emulsion is permanent. Thus it is evident that there are two general methods by which the stability of an emulsion may be decreased—first, by an attack upon the emulsifying agent, and second, by increasing the surface tension at the interface.

Chemically, the attack upon the emulsifying agent may be made by destroying it, or by converting it into an ineffective form. The ideal method, of course, is to destroy it and thus give surface tension, however small, an unrestricted opportunity to cause coalescence, but this is frequently impossible or impracticable. To convert the emulsifying agent into an ineffective form, a substance may be added that dissolves it and thus removes it from the interface; or one that flocculates it to such an extent that a coherent film is no longer formed; or one that tends to form the reverse type of emulsion—a counter-colloid.

In most, if not all, emulsions there is an electric charge upon the globules of the dispersed phase. According to Sir Oliver Lodge[3] an electric charge on a drop causes a slight distending force which tends to diminish surface tension; this tendency is vastly increased as the drop grows smaller, because surface tension varies inversely as the simple diameter of the drop, while the electric tension varies inversely as the fourth power of the diameter; hence, when a certain minimum size is reached, the two opposing tendencies become equal and the drop behaves as if flat. Lewis[4] used this idea as a basis for a theory of emulsification which, while seeming to fit the facts in many ways, does not seem capable of proof.[5] It is safe, however, to assume that the electric charge upon a globule of the dispersed phase of an emulsion materially reduces surface tension, and that if the charge is large (probably due to adsorbed ions of electrolytes in solution in the water) it may contribute to the stability of the emulsion to a considerable extent. In some such cases the neutralization of the electric charge results in the increase of surface tension to such an extent that the film of emulsifying agent is no longer able to prevent coalescence.

In many emulsions a marked lowering of surface tension is due to an inherent property of the emulsifying agent, and it can be increased only by destroying or modifying the latter. In view of the foregoing it becomes increasingly apparent that in order to control intelligently the breaking of an emulsion it is necessary first to determine the nature and properties of the emulsifying agent.

Previous Work on Petroleum Emulsions

In the case of crude petroleum emulsions, the emulsifying agent (asphalt) cannot be destroyed. Hydrophile (water-soluble) colloids that are strongly interfacial should, however, render it ineffective, because of their tendency to form emulsions of the reverse type. Considerable success appears to have been attained with this class of compound[6] in the mid-continental fields, but it is far from a universal remedy. The great difficulty lies in conveying the aqueous solution of the colloid through the enveloping oil to the dispersed water, which it must reach in order to be effective. As far as known, this method has not proved successful on emulsions from California fields. The latest development along this line is the "oil-soluble" hydrophile colloid.[7] This should be more effective.

While experimenting upon an emulsion from a Texas field Sherrick[8] found that the water globules carry a negative electric charge and that the water can be precipitated by neutralizing this charge. He also found that the efficiencies of acids in neutralizing the charge are directly proportional to their hydrogen ion concentration—thus, in order of efficiency: hydrochloric, sulphuric, acetic acids—and that other electrolytes with strongly adsorbed positive ions also neutralized the charge and precipitated the water, notably ferric chloride and ferric nitrate. He also reported that the extent to which the negative ion is adsorbed simultaneously with the positive ion is of considerable importance.

Early Experiments

The first work done on petroleum emulsions by the writer was an attempt to repeat some of Sherrick's experiments, using an emulsion from the Midway-Sunset field of California. It was easy to prove that the water globules carry a negative charge. When a sample of the emulsion was put into a U-tube and a direct current of 250 volts impressed upon it by means of an electrode in each arm, the arm containing the positive electrode became black, and the one containing the negative electrode became lighter brown in color than formerly. On the positive side the negative water globules had migrated to the electrode, leaving the pure black oil against the glass; on the negative side the water globules were repelled to the glass, where their increased concentration resulted in the lighter brown color.

When the acids were tried, it was found that their order of efficiency was the reverse of that found by Sherrick, and that considerable heat and time were necessary in all cases. Sulphuric acid combined with the oil and, therefore, would not work at all. Hydrochloric acid in high concentrations caused some precipitation of water. Acetic acid precipitated the water most completely, in the least time and with the least amount of heat.

Ferric chloride and ferric nitrate solutions were merely incorporated in the emulsion. Some other salts, such as ferric sulphate and calcium chloride, caused some minor coalescence of the water globules after long heat-treatment. On the whole the action of electrolytes

alone, on California emulsions, was not sufficient to encourage further investigation.

However, it was later found that if a substance that is soluble in both phases of the emulsion is added with the acids, the efficiencies of the latter are as found by Sherrick. The use of this class of substances as an aid in the resolution of crude petroleum emulsions is the principal subject of this paper.

Selection of Oil-Soluble Substances

Since the asphalt film around the water globules behaves as if it is, to all intents and purposes, insoluble in both phases, it was decided to conduct a search for some oil-soluble substance small amounts of which would destroy, or at least greatly modify, this film and thus permit the water globules to coalesce. In the preliminary experiments it happened that of the first three tried, one was practically insoluble in water, one slightly soluble and the third soluble to a considerable extent. The results seemed to be in proportion to this solubility, and therefore the series in the following table was tried in order to determine if any such generalization could be made.

In each case 2 cc. of the substance was added to 20 cc. of emulsion containing 25.6 per cent of water by volume, in a 100-cc. centrifuge tube, and heated to 45 deg. C. Each tube was then shaken by hand for 1 minute, and then kept at a temperature of 45 deg. C. for 3 hours. After this period it was centrifuged for 5 minutes by means of an electric centrifuge, and the amount of water thrown down noted.

Chemical	Solubility in 100 cc. Water, Grams	Water Precipitated, cc.
Carbon tetrachloride	0.08	0.0
Amyl nitrite	1 2	0 1
Fusel oil	3.0	4 8
Aniline	3.5	5.0
Butyl and propyl alcohols (mixed)	5.0	5.0
Ethyl acetate	8.6	0 5
Acetone	All proportions	1 5
Butyric acid	All proportions	6.0

The solubilities given above for amyl nitrite, fusel oil and the butyl-propyl alcohol mixture are rough determinations made in this laboratory, but are sufficiently accurate for the purpose. It is quite apparent that the effect of oil-soluble substances cannot be predicted by their solubility in water alone; other properties are also important—probably, chiefly, the extent to which they will mix with asphalt, and the presence of a strongly adsorbed positive ion. It was concluded, however, that no oil-soluble substance is likely to have a marked tendency to aid in the breaking of an emulsion unless it is also water-soluble to a considerable degree. This conclusion in regard to mutual solubility has been proved sound by the results of all experiments later performed.

Acidified Mutually Soluble Substances Effective

It will be remembered that of the acids tried upon this emulsion, acetic was decidedly the most effective—it is undoubtedly somewhat soluble in the oil. The action of butyric acid, which is miscible in all proportions with both phases, is rapid and complete. This led to the idea of conveying a readily adsorbed positive ion through the enveloping oil to the water globules by means of a mutually soluble substance. The first application of this idea was made with acidified fusel oil.

In the following tests 100 cc. of emulsion was treated with 5 cc. of acetic acid and fusel oil in the various proportions shown in the following table. The mixtures were placed in 500-cc. graduated cylinders, agitated for 2 minutes by means of a 1½-in. propeller revolving at 3,500 r.p.m., and then heated to 45 deg. C. for 24 hours on a steam radiator. After 24 hours the condition of the emulsion in each case was noted.

Chem. Mixture 5 cc. Acid	Fusel Oil	Results
5	0	Emulsion slightly darker in color.
4	1	Green-black color; perceptible coalescence of water into globules at bottom of cyliner.
3	2	Same as above, but globules of water very much larger—up to 1/16 in. diameter.
2	3	In addition to very large globules, some water precipitated.
1	4	Practically complete precipitation of water.
0	5	Emulsion slightly darker in color.

Untreated petroleum emulsion is chocolate-brown in color. When the water globules coalesce to macroscopic size, the color changes to black. Thus a color change is an accurate indication of a change in degree of dispersion of the water.

This experiment showed that a small amount of acetic acid in the presence of a mutually soluble substance is far more effective in breaking petroleum emulsions than either chemical alone. Similar experiments, in which the actions of acetic, hydrochloric and sulphuric acids were compared, resulted in concurrence with Sherrick's conclusion that acids that ionize readily are most effective.

Tests With Phenol

A search was made among the organic compounds for mutually soluble substances, with the hope that something cheap, and effective in minute amounts, would be found. Phenol proved to be the most suitable substance encountered. The following standard manipulation was adopted for its thorough testing.

The Emulsion—The emulsion used in these tests was obtained from the General Petroleum Corporation, Taft, Calif. The gravity was 19 deg. Bé. and the emulsion contained 35 per cent of water by volume—thus each sample of 150 cc. contained 52.5 cc. water.

Sample—150 cc. of emulsion in a 500-cc. graduated cylinder.

Chemicals—As indicated in the tables of results.

Heat—50 deg. C. in a water bath for 1 hour before the addition of the chemicals and agitation, and for 2 hours after. The heat was turned off at the end of this period, but the samples were left in the water bath while it was cooling. A circular tank 2 ft. in diameter and 8 in. deep, filled with water to depth of 6 in., was used for the water bath.

Agitation—Two minutes with a 1½-in. propeller, revolving at 3,500 r.p.m., unless otherwise stated in the table.

Twenty-four Hours After Agitation—The samples were heated in the water bath to 50 deg. C. The purpose of this heating was to make the oil more fluid so that it could be handled with a pipette readily, but it also undoubtedly had some effect upon the emulsion. Then the top 50 cc. of each sample was withdrawn with a pipette, diluted with 50 cc. of gasoline, and centrifuged for 5 minutes to determine the water content of this layer. Part of the water often came down as an emulsion, therefore both free water and emulsion were recorded. (Column No. 1 in the tables which follow.) The remainder of the sample was slowly stirred with a glass rod, and the amount of free water in the bottom of the cylinder noted. (Column No. 2.) The purpose of the stirring was to cause the large globules of free water to coalesce and settle.

Constant Factor—When there was a constant factor other than those already stated, it is stated at the top of the table.

Color Change—The untreated emulsion is brown and the clean oil is black. Experience has shown that a darkening of color indicates coalescence of the water globules.

The phenol used in all the experiments was made liquid by the addition of 15 per cent of water.

TABLE I—EXPERIMENTS HAVING AS A CONSTANT FACTOR—1 CC. PHENOL

Variable Factor	1 Top 50 cc. Water cc.	1 Top 50 cc. Emulsion, cc.	2 Free Water in Cylinder cc.	Color Change

It is quite apparent from the results tabulated in Table I that the emulsified water was alkaline and that enough acid was required to make it distinctly, but not necessarily strongly, acid.

Having determined the minimum amount of sulphuric acid that would give good results, the tests reported in Table II were made to see to what extent the amount of phenol could be cut down.

Thus the minimum amount of chemicals that could be used and still get good results was 0.75 cc. of phenol plus 0.2 cc. of sulphuric acid to 150 cc. of emulsion. This is an incomparably smaller amount than is necessary when acid alone is used, and the time and heat necessary are also much less.

The rapid increase in the amount of acid necessary to produce a separation when the amount of phenol used was cut down is shown in Table III.

The heavier oil fractions were removed from a quantity of emulsion by diluting with gasoline and centrifuging. This resulted in a "sludge" containing about the same amount of water (35 per cent) as the original emulsion, but differing from it in that the water was suspended in impure gasoline instead of in crude petroleum. Table IV shows the results obtained when some of this sludge was treated with phenol and acid in the

usual manner. It will be noted that it does not respond to treatment as readily as ordinary petroleum emulsion. This tends to substantiate the opinion expressed earlier in this paper, that the efficiency of asphalt as an emulsifying agent probably depends upon the nature of the oil in which it is dissolved.

Acid Sludge Studies

Refinery acid sludge is a complex byproduct obtained when petroleum distillates are purified with sulphuric acid. Besides acid, it is said to contain aromatic compounds and other organic substances some of which might be expected to be soluble both in oil and in water. It was therefore decided to test this sludge. Kerosene acid sludge was used.

In all cases the free water that settled out was acid to methyl orange; when only 1 cc. of sludge was used, this acidity was very slight. In all cases, except the last, the oil was tested for acidity (after the free water had settled out) and found to be acid to methyl orange. The test was made by shaking distilled water with the oil, and then centrifuging the water out and testing it with methyl orange.

By titration with a standardized solution of sodium hydroxide, 1 cc. of the sludge was found to be equivalent in acidity to 0.4 cc. of sulphuric acid. It is apparent from the results shown in Table V that something besides the acidity of the sludge is active in precipitating the water from the emulsion; an equivalent amount of sulphuric acid will not produce comparable results unless phenol is also present. This probably is due to the mutually soluble substances in the sludge. When the content of this class of compounds was increased by the addition of varying amounts of phenol, it was found, as shown in the tables to follow, that the acid sludge could be reduced to an amount roughly equivalent in acidity to the minimum effective amount of sulphuric acid.

* Water was acid to methyl orange

† Oil was acid to methyl orange.

‡ Water was neutral to methyl orange.

It was later found that all emulsions do not respond to this treatment with equal readiness. Another shipment, presumably from the same well, was found to require a higher temperature, and, when phenol and sulphuric acid were used, a considerable increase in the amounts of the reagents. It was therefore concluded that each emulsion is an individual problem from the standpoint of this method of treatment.

A Theory of Explanation

The explanation of the breaking of petroleum emulsions by mutually soluble substances is not clear. At first sight the decrease in interfacial tension due to their presence would seem likely to promote, rather than prevent, emulsification, but this effect apparently is of small importance compared with others tending to decrease stability. When a mutually soluble substance is used alone, a comparatively large amount is necessary to have any apparent effect upon the stability of an emulsion; the results, if any, are undoubtedly due largely to the solvent effect upon the asphalt films around the water globules. When acid is also present, the amount of mutually soluble substance necessary to cause coalescence is often so small that it is not reasonable to attribute the result to solvent effect. It is entirely reasonable, however, to assume that the mutually soluble substance conveys the acid through the enveloping oil to the dispersed water; and that, having come in contact with the water, the H ion of the acid neutralizes the negative charges thereon and thus establishes conditions favorable for coalescence.

If this view is sound it is reasonable to suppose that other electrolytes with strongly adsorbed positive ions can be substituted for the acids, provided such electrolytes are soluble in the mutually soluble substance. This was not tried.

The further investigation of the mutual solubility idea was carried out with sulphur dioxide gas. The latter, being an acid gas that is soluble both in water and in some of the fractions of crude oil,[9] should break an emulsion if enough of it could be forced to stay in solution while the emulsion is being heated. Considerable success was attained in breaking petroleum emulsions when small samples in test tubes were saturated with the gas under from 5 to 10 lb. pressure for 1 hour, and then heated to 50 deg. C. When large samples were used, the results proved unsatisfactory.

Conclusions

There are two antagonistic forces at the interface between the phases of an emulsion—namely, interfacial tension, which tends to cause coalescence, and the coherence of the film of emulsifying agent, which tends to resist coalescence. The stability of an emulsion depends upon the relative magnitudes of these opposing forces.

There are, therefore, two general methods by which the stability of an emulsion may be decreased—first, by an attack upon the emulsifying agent, and second, by increasing the surface tension at the interface.

The emulsifying agent in petroleum is probably asphalt. The coherence of the film of asphalt depends to a considerable extent upon the nature of the oil—an excess of light fractions seeming to promote the formation of a coherent film.

The dispersed water globules of a petroleum emulsion carry negative charges which decrease the surface tension at the interface. When these charges are neutralized, surface tension at the interface is increased to such an extent that the films of asphalt are no longer able to prevent coalescence, and the emulsion breaks.

Petroleum emulsions may be broken in this manner by the use of electrolytes having strongly adsorbed positive ions, provided the electrolytes can be conveyed through the enveloping oil to the dispersed water. Ordinarily this can be done only with extreme difficulty when electrolytes alone are used, and even then only when the latter are present in excessive amounts.

Petroleum emulsions can be broken readily by means of very small amounts of acid if a small amount of a substance that is soluble in both phases is also introduced. The mutually soluble substance conveys the acid through the enveloping oil to the dispersed water.

Any mutually soluble substance should be expected to act in this manner. Of those tested, phenol is the most satisfactory. Kerosene acid-sludge contains mutually soluble substances, but not in sufficient quantity to be very effective. When a small amount of phenol is added to kerosene acid-sludge, the mixture is more effective for breaking emulsions than phenol and acid.

A certain amount of heat is necessary when using this method.

The amount of acid necessary is very small. It is not known whether enough is left in the oil to injure pipe lines and equipment or not.

Sulphuric Acid From Ferric Sulphate

Sulphuric dioxide may be used to oxidize ferrous iron when making a leaching solution to contain both sulphuric acid and ferric iron. This solution can be used as a leaching agent for the recovery of copper from oxidized ore or sulphide ores, or a mixture of these ores. SO_2 accelerates the oxidation of ferrous iron and the percentage of SO_2 present affects the rapidity with which the ferric iron breaks down for the formation of sulphuric acid. The Bureau of Mines station at Tucson, Ariz., has found that when the concentration of the SO_2 entering or bubbling through the solution containing ferrous iron is less than ½ of 1 per cent, the formation of ferric iron proceeds more rapidly than does the breaking down of the ferric iron to form sulphuric acid. Under these conditions, it is practical to change all of the ferrous iron to ferric iron with the formation of some sulphuric acid. As the percentage of SO_2 in the entering gas increases, more of the ferric iron is broken down, so that a concentration of SO_2 can be obtained which will effect a complete reduction of all the ferric iron to ferrous iron with production of a corresponding amount of sulphuric acid. By suitably controlling the concentration of the SO_2 in the gas applied to the operation, the proportion of ferric sulphate to sulphuric acid in the final solution may be varied according to the requirements of any particular case. The rapidity of the oxidation is directly proportional to the volume of gas. Maximum oxidation is obtained in neutral solution. Reaction is retarded in the presence of free acid.

Contraction and Shrinkage During Casting*

BY ROBERT J. ANDERSON
Metallurgist, U. S. Bureau of Mines

LITTLE information has been published relating to accurate measurements of the linear contraction of the non-ferrous casting alloys and the total contraction in volume of alloys on passing from the liquid to the solid state. In foundry practice, patterns are usually made on the basis of a general figure for linear contraction of a given class of alloys—for example, aluminum alloys, brasses or bronzes—irrespective of the alloy employed. For instance, in making light aluminum alloy castings a general figure of 0.156 in. per foot is employed as the pattern allowance, although measurements by the Bureau of Mines show that in forty alloys the range was from about 0.05 to 1.80 per cent.

When a metal or alloy is cooled from the liquid state at any temperature to the solid state at any temperature — say to room temperature — its diminution in volume is the algebraic sum of three separate contractions — namely, (1) in cooling from any temperature in the liquid state to the freezing point; (2) in passing from the liquid state at the freezing point to the solid state at the melting point; and (3) in cooling from the solid state at the melting point to any lower temperature. These three contractions in volume have been termed respectively, (1) the liquid shrinkage, (2) the solidification shrinkage, and (3) the solid shrinkage. Reliable data as to the contraction of the various metals on passing from the liquid state to the solid state are scant, but on the basis that practically every well-defined property of the elements is a function of their symbol weights, it may be deduced that the contraction in volume of the metals is a periodic function of their atomic weights.

DEFINITION OF TERMS

The liquid shrinkage may be considered to be the amount of contraction in volume of a metal or alloy in the liquid state on cooling from any temperature in the liquid state to the freezing point. The greater the temperature interval through which the metal cools —that is, the higher the initial temperature of the melt—the greater the liquid shrinkage. The liquid shrinkage of a metal or alloy, therefore, is not a definite numerical value; but it varies with the temperature interval of cooling. Thus the weight of metal that can be poured into a mold at a higher temperature is less than at a lower temperature.

The solidification shrinkage may be defined as the contraction in volume of a metal or alloy on passing from the liquid state at the freezing point to the solid state at the melting point. Where an alloy solidifies over a freezing range, the solidification shrinkage is the contraction in volume which occurs from the beginning to the end of freezing. The actual amount of the solidification shrinkage varies considerably for different metals and alloys, and it may be markedly affected by the presence of impurities. So far as is known, bismuth and silicon are the only metals that expand on solidification, but a number of alloys expand; and some show expansions on cooling from liquid to solid, although the total volume change is a decrease.

*Extracted from "Reports of Investigations," Serial 2410, November, 1922.

The solid shrinkage is the contraction in volume of a metal or alloy on cooling from the solid state at the melting point to any lower temperature—usually the ordinary temperature—and it may be determined over any solid temperature range by experimental measurements or by calculation from the formula for expansivity. Ordinarily, in foundry practice, the solid shrinkage may be regarded as the contraction in volume on cooling from solid metal at the melting point to about room temperature. The thermal expansivity is the reciprocal of the solid linear contraction.

The linear contraction of a metal or alloy is the diminution of length that takes place in a casting on cooling in a mold. The terms linear contraction and pattern maker's shrinkage are synonymous. Turner states that the shrinkage may be defined as the difference between the length of a casting and that of the pattern from which it was produced—that is, it is the difference in volume between the fluid metal in the mold and the resultant casting at the ordinary temperature. Shrinkage in this sense, therefore, does not take into account the various stages of contraction, arrest or expansion which may occur in an alloy; but represents the final volume change. In experimental measurements, the linear contraction may be most readily determined by measuring the diminution in length of a bar cast from a pattern of definite length. It may be expressed in percentage diminution in length, in inch per foot, or in terms of the patternmaker's shrinkage scale.

PATTERNMAKER'S SHRINKAGE

In pattern practice for light aluminum alloy castings, the usual allowance for the shrinkage is $\frac{5}{32}$ in. per foot (0.156 in., or 1.30 per cent); and if a casting is to be 1 ft. long, then the pattern is made 1 ft. and $\frac{5}{32}$ in. in length. According to Keep (and his version of the matter is accepted also by Turner and others), the general understanding is that the shrinkage of a casting is the difference in length (or any other linear dimension) between the casting and the pattern from which it was made; or rather between it and the mold in which it was cast. Thus, the general figure for the shrinkage of gray cast iron is $\frac{1}{8}$ in. per foot, and the pattern maker, in taking measurements for the different dimensions of a pattern, uses a "shrink rule" which is $\frac{1}{8}$ in. longer than the standard foot-rule which is used to measure the castings.

West, however, calls "shrinkage" the decrease in volume in the liquid state, which requires feeding in casting practice and applies the term "contraction" to the decrease in volume which takes place after solidification. Also, according to McWilliam and Longmuir, "technically, 'shrinkage' refers to the gradual lessening in volume of the fluid metal as it approaches the solidification point at which 'shrinkage' ceases and contraction commences, the latter being understood to refer to the lessening in length or in volume of the solid metal." Hailstone states that "liquid contraction" is the local contraction which takes place in the heavy part of a casting when the outside skin of that casting has solidified. He states also that "solid contraction" is the natural contraction which metals undergo when passing from the hot to the cold condition; solid contraction is also known as shrinkage. The arbitrary terminology applied by West and others to contraction in the liquid and solid states seems to be based on nothing rational, and the writer prefers the terminology of Keep and Turner, which is technically correct.

It was later found that all emulsions do not respond to this treatment with equal readiness. Another shipment, presumably from the same well, was found to require a higher temperature, and, when phenol and sulphuric acid were used, a considerable increase in the amounts of the reagents. It was therefore concluded that each emulsion is an individual problem from the standpoint of this method of treatment.

A Theory of Explanation

The explanation of the breaking of petroleum emulsions by mutually soluble substances is not clear. At first sight the decrease in interfacial tension due to their presence would seem likely to promote, rather than prevent, emulsification, but this effect apparently is of small importance compared with others tending to decrease stability. When a mutually soluble substance is used alone, a comparatively large amount is necessary to have any apparent effect upon the stability of an emulsion; the results, if any, are undoubtedly due largely to the solvent effect upon the asphalt films around the water globules. When acid is also present, the amount of mutually soluble substance necessary to cause coalescence is often so small that it is not reasonable to attribute the result to solvent effect. It is entirely reasonable, however, to assume that the mutually soluble substance conveys the acid through the enveloping oil to the dispersed water; and that, having come in contact with the water, the H ion of the acid neutralizes the negative charges thereon and thus establishes conditions favorable for coalescence.

If this view is sound it is reasonable to suppose that other electrolytes with strongly adsorbed positive ions can be substituted for the acids, provided such electrolytes are soluble in the mutually soluble substance. This was not tried.

The further investigation of the mutual solubility idea was carried out with sulphur dioxide gas. The latter, being an acid gas that is soluble both in water and in some of the fractions of crude oil,[9] should break an emulsion if enough of it could be forced to stay in solution while the emulsion is being heated. Considerable success was attained in breaking petroleum emulsions when small samples in test tubes were saturated with the gas under from 5 to 10 lb. pressure for 1 hour, and then heated to 50 deg. C. When large samples were used, the results proved unsatisfactory.

Conclusions

There are two antagonistic forces at the interface between the phases of an emulsion—namely, interfacial tension, which tends to cause coalescence, and the coherence of the film of emulsifying agent, which tends to resist coalescence. The stability of an emulsion depends upon the relative magnitudes of these opposing forces.

There are, therefore, two general methods by which the stability of an emulsion may be decreased—first, by an attack upon the emulsifying agent, and second, by increasing the surface tension at the interface.

The emulsifying agent in petroleum is probably asphalt. The coherence of the film of asphalt depends to a considerable extent upon the nature of the oil—an excess of light fractions seeming to promote the formation of a coherent film.

The dispersed water globules of a petroleum emulsion carry negative charges which decrease the surface tension at the interface. When these charges are neutralized, surface tension at the interface is increased to such an extent that the films of asphalt are no longer able to prevent coalescence, and the emulsion breaks.

Petroleum emulsions may be broken in this manner by the use of electrolytes having strongly adsorbed positive ions, provided the electrolytes can be conveyed through the enveloping oil to the dispersed water. Ordinarily this can be done only with extreme difficulty when electrolytes alone are used, and even then only when the latter are present in excessive amounts.

Petroleum emulsions can be broken readily by means of very small amounts of acid if a small amount of a substance that is soluble in both phases is also introduced. The mutually soluble substance conveys the acid through the enveloping oil to the dispersed water.

Any mutually soluble substance should be expected to act in this manner. Of those tested, phenol is the most satisfactory. Kerosene acid-sludge contains mutually soluble substances, but not in sufficient quantity to be very effective. When a small amount of phenol is added to kerosene acid-sludge, the mixture is more effective for breaking emulsions than phenol and acid.

A certain amount of heat is necessary when using this method.

The amount of acid necessary is very small. It is not known whether enough is left in the oil to injure pipe lines and equipment or not.

Acknowledgment

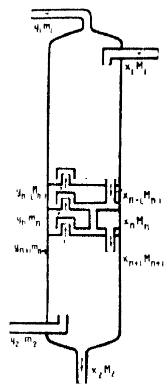
Sulphuric Acid From Ferric Sulphate

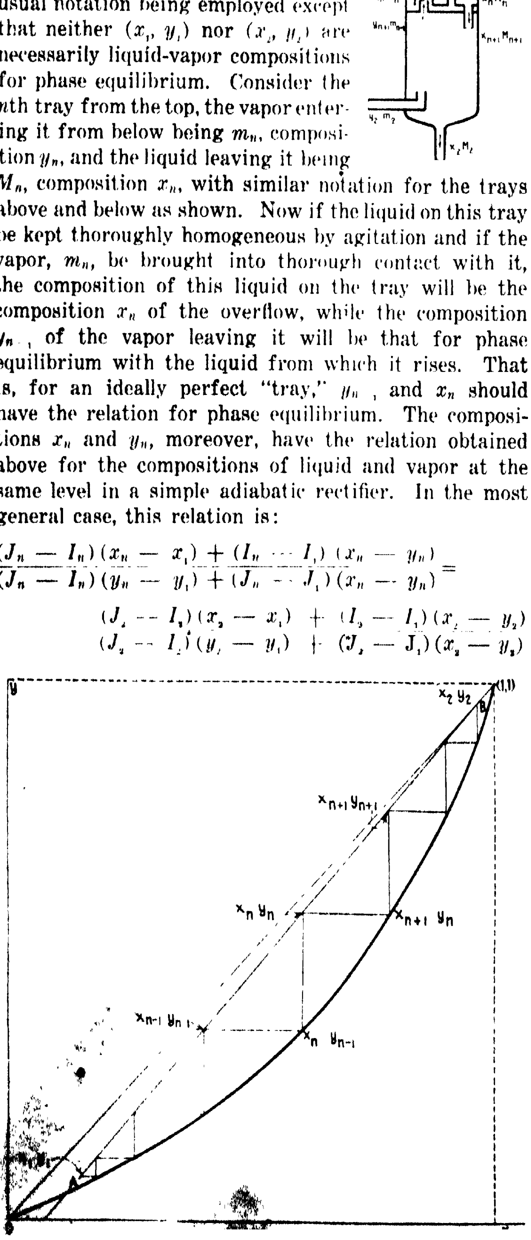
Sulphuric dioxide may be used to oxidize ferrous iron when making a leaching solution to contain both sulphuric acid and ferric iron. This solution can be used as a leaching agent for the recovery of copper from oxidized ore or sulphide ores, or a mixture of these ores. SO_2 accelerates the oxidation of ferrous iron and the percentage of SO_2 present affects the rapidity with which the ferric iron breaks down for the formation of sulphuric acid. The Bureau of Mines station at Tucson, Ariz., has found that when the concentration of the SO_2 entering or bubbling through the solution containing ferrous iron is less than ½ of 1 per cent, the formation of ferric iron proceeds more rapidly than does the breaking down of the ferric iron to form sulphuric acid. Under these conditions, it is practical to change all of the ferrous iron to ferric iron with the formation of some sulphuric acid. As the percentage of SO_2 in the entering gas increases, more of the ferric iron is broken down, so that a concentration of SO_2 can be obtained which will effect a complete reduction of all the ferric iron to ferrous iron with production of a corresponding amount of sulphuric acid. By suitably controlling the concentration of the SO_2 in the gas applied to the operation, the proportion of ferric sulphate to sulphuric acid in the final solution may be varied according to the requirements of any particular case. The rapidity of the oxidation is directly proportional to the volume of gas. Maximum oxidation is obtained in neutral solution. Reaction is retarded in the presence of free acid.

The problem, just considered, as to the actual conditions at the bottom of a rectifier has an intimate connection with that of the conditions existing in a rectifier containing a finite number of so-called "trays," or liquid reservoirs such as commonly employed. In all the above theory we have assumed perfect contact at every level between descending liquid and ascending vapor, and for perfect rectification we assumed that at the top and also at the bottom the liquid and vapor in contact were in phase equilibrium, although the equations we have written must be satisfied independently of phase relations. In a rectifier, however, containing a finite number of trays, there are certain limitations that must be taken account of.



Consider a rectifier as shown in the diagram where the only liquid entering it is admitted at the top, our usual notation being employed except that neither (x_1, y_1) nor (x_2, y_2) are necessarily liquid-vapor compositions for phase equilibrium. Consider the nth tray from the top, the vapor entering it from below being m_n, composition y_n, and the liquid leaving it being M_n, composition x_n, with similar notation for the trays above and below as shown. Now if the liquid on this tray be kept thoroughly homogeneous by agitation and if the vapor, m_n, be brought into thorough contact with it, the composition of this liquid on the tray will be the composition x_n of the overflow, while the composition y_{n-1} of the vapor leaving it will be that for phase equilibrium with the liquid from which it rises. That is, for an ideally perfect "tray," y_{n-1} and x_n should have the relation for phase equilibrium. The compositions x_n and y_n, moreover, have the relation obtained above for the compositions of liquid and vapor at the same level in a simple adiabatic rectifier. In the most general case, this relation is:

$$\frac{(J_n - I_n)(x_n - x_1) + (I_n - I_1)(x_n - y_n)}{(J_n - I_n)(y_n - y_1) + (J_n - J_1)(x_n - y_n)} = \frac{(J_2 - I_1)(x_2 - x_1) + (I_2 - I_1)(x_2 - y_2)}{(J_2 - I_2)(y_2 - y_1) + (J_2 - J_1)(x_2 - y_2)}$$



With specified values of the end compositions, x_1, y_1, x_2, y_2, the above equation, with x_n, y_n considered as variables, determines a plain curve connecting the two points (x_1, y_1) and (x_2, y_2) on the x, y diagram. The values of I_n and J_n at the various points (x_n, y_n) would be determined by the physical properties of the mixture dealt with.

For a mixture whose latent heats at constant pressure follows the proportionality relation discussed above, the equation just written is somewhat simplified, as we have seen, while for equal latent heats of the pure constituents it is the equation of a straight line connecting the points (x_1, y_1) and (x_2, y_2).

In the diagram let 0-(1,1) represent the equilibrium curve, while AB represents the locus of the above equation between x_n and y_n. Then with the values of the end compositions, (x_1, y_1) and (x_2, y_2) as shown, it may be seen that the minimum possible number of trays is equal to the number of segments into which the line AB has been divided by the various points (x_n, y_n) . . .

The diagram shows that if either of the two points (x_1, y_1) or (x_2, y_2) is located on the equilibrium curve, 0-(1,1)—i.e., if at either end we assume phase equilibrium between descending liquid and ascending vapor, the number of "trays" required will be infinite, as we should expect.

Continuation of this series of articles will be published in a subsequent issue.

Suggested Research Problems in Eletrochemistry

The American Electrochemical Society has issued a booklet of suggestions to authors, embodying some of the standards set by the society for papers presented before its meetings.

The following list of research problems is suggested as fruitful subjects for future papers:

Electrolytic Deposition of Brasses and Bronzes.
Hydrogen Potential Measurements of Aqueous Electrolytes.
Electrochemistry of Concentrated Solutions.
Electrolytic Production of Organic Compounds.
New Uses for Chlorine and Caustic.
Electrolytic Production of Lithium Hydrate.
Studies of the Properties of the Alkaline Earth Alloys.
Effect of Impurities in the Electrolysis of Fused Magnesium Salts.
The Electrochemistry of Gaseous Conduction.
Electrical Conductivity of Metals and Alloys Above Melting Point.
Stability of the Metal Carbides at Elevated Temperatures.
Revised Melting Point Determination of Refractory Oxides, Pure and Commercial.
Stability of the Metal Silicides at Elevated Temperatures.
Energy Losses in Electric Furnaces.
Gaseous Reduction of Metal Compounds.

Properties of Wood in Paper Making*

The Effect of Physical and Chemical Properties of the Wood on Economy and Quality, Particularly in the Sulphite Process

BY BJARNE JOHNSEN and H. N. LEE

THE suitability of any kind of wood for paper making is determined by its physical and chemical characteristics. Very resinous woods, like the pines, are not suitable for the sulphite process, but make an excellent raw material for the sulphate or kraft process. Soda pulp from poplar is used in certain papers such as book papers on account of the short, bulky fiber, but cannot be used for papers where strength is required. It is not the intention of this paper to discuss the value of the various species of wood for all different pulping processes and for the different grades of paper. This discussion will deal chiefly with the most important pulpwoods, spruce and balsam, and their use in the sulphite process, which is by far the most important chemical process. However, much of the data given may be equally well applied to other woods and other processes.

In discussing the properties of wood for paper making there are two chief considerations—economy and quality. Wood is ordinarily purchased on the cord basis and the consumption of wood is recorded on the cord basis. It is customary to express the yield of pulp in terms of cords used per ton of pulp, but while the enormous variations in this figure in different mills may, to a great extent, be accounted for in the different methods used in the manufacturing process, it is not possible so to explain the great variations which are experienced in any one mill. These variations can be explained only when the actual value of the cord based on the physical and chemical properties of the wood are known.

MEASUREMENT OF CORD WOOD

Considering first the physical properties, it is known that a very large variation can exist in the amount of solid wood in the cord. According to Sterns[1], the theoretical solid content of the cord is always the same provided the logs are all of the same diameter. In this case the theoretical solid content is 90.69 per cent (116.1 cu.ft.). If the logs differ in diameter, the solid content will be greater and will increase as the ratio of the largest diameter to the smallest increases. However, in actual measurements he found no cords contained over 80 per cent (102.4 cu.ft.) solid wood. He also found that the average solid volume per cord of 32-in. wood, based on careful volumetric measurement of 34 cords, logs from 4 to 16 in. diameter, to be, before barking, 93.97 cu.ft., after barking 83.36 cu.ft.

TABLE I—CUBIC FEET PER CORD

	Graves[2]		Winslow and Thalen[3]			
Length	Over 5.5 In. Diameter at Small End	2.5 to 5.5 In. Diameter at Small End	Mixed	Straight	Crooked	Knotty
30 in.	90.5	83.9	87.2		..	
4 ft	88.9	82.4	85.7	92	82	74
8 ft	83.8	77.2	80.5	82	75	50

TABLE II—SOLID CONTENT OF WOODS FROM MINNESOTA AND QUEBEC

	Average Que.	Average Minn.	Maximum Que.	Maximum Minn.	Minimum Que.	Minimum Minn.
Number of logs per cord	67	115	102	156	36	86
Average diameter inches, per cord	7.31	5.67	10.56	6.50	5.96	4.95
Cubic feet solid material per cord	88.58	85.68	99.52	91.72	69.79	77.82

Our own measurements on two very different kinds of wood, one coming from northeastern Quebec and the other from Minnesota, based on 32 cords of each class of wood, are given in Table II.

The Quebec wood was peeled, the Minnesota wood not peeled; therefore the actual wood in the latter was about 12.5 per cent less, or an average of about 75 cu.ft. per cord. The greatest variation in the amount of solid wood was due to poor packing, which in turn was frequently due to crooked or poorly trimmed logs. The figures appear to show conclusively that wood of larger average diameter, which means a mixture of small, medium and large diameters, results in more actual solid wood per cord than wood of small average diameter.

In most cases investigators have found that the larger the average diameter the greater the solid content, but Sterns found just the reverse. He believes the discrepancy may be explained by the fact that he measured 32-in. wood, while the others, in general, measured 4-ft. or 8-ft. wood. It is certainly true that the effect of crookedness of logs is greater in long logs than in short ones and it is possible that in very short logs the effect of crookedness might be comparatively small. Moreover, large diameter logs are more likely to be straight than are those of small diameter.

It has been shown in the foregoing that the actual value of a cord of wood for production of pulp, or in other words the solid wood in a cord, may be influenced by several factors and may vary considerably. To secure reliable figures from which to determine yield, as well as to handle the purchase of wood in the most efficient manner, it is quite apparent that accurate measurement of the wood is necessary.

DENSITY AND RATE OF GROWTH

The value of a given volume of solid wood for pulp is determined by the dry weight of the wood. This is dependent on the density of the wood. This varies not only with the species but also within the same species according to the conditions of growth.

Our investigations show in balsam as well as in spruce, and the same may probably be applied to other coniferous woods, that slow growth wood is more dense than rapid growth wood. The figures for logs 6 in. in diameter are given in Table III.

Moreover, as is shown in Table IV by Kress, Wells and Edwards[4], there is considerable variation in the average density of different species of wood.

Results of tests by the authors are given in Table V.

From these data it is apparent that spruce has, on the average, 15 to 20 per cent greater density than balsam fir. Here again, as in the case of cord wood measure, are opportunities for large variations in the possible yields from cords of wood composed of more than one species or even composed of the same species of different rates of growths.

TABLE III—EFFECT OF RATE OF GROWTH ON DENSITY

	Rings, Per In	Weight, Cu Ft Dry Green Wood
Quebec spruce	18.5	27.6
	4.5	20.2
Minnesota spruce	17.4	28.0
	5.7	22.4
Quebec balsam	19.7	27.2
	4.3	18.7
Minnesota balsam	10.3	22.6
	6.4	17.8

TABLE IV—DENSITY OF DIFFERENT WOODS

	Average Weight Of 1 Cu Ft of Dry Green Wood
Black spruce (*Picea mariana*)	23
White sprice (*Picea canadensis*)	24
Balsam fir (*Abies balsamea*)	21
Hemlock (*Tsuca canadensis*)	24
Jack pine (*Pinus divaricata*)	24
Aspen (*Populus tremuloides*)	23

TABLE V—RATE OF GROWTH AND DENSITY OF CANADIAN WOODS

	Average Weight Of 1 Cu.Ft of Dry Green Wood	Rings per In
N. E. Quebec spruce	25.2	12.8
S. W. Ontario spruce	25.6	11.5
N. E. Quebec balsam	20.8	9.1
S. W. Ontario balsam	20.4	8.2

Chemical Composition

Another factor which influences the possible yield, even when the foregoing factors are eliminated, is the chemical composition of the wood. The most important characteristic is the cellulose content. The data on this subject from different sources are not always comparable, because the various investigators have not used the same methods in making their determinations. The relative cellulose content of certain kinds of wood, based on a comparatively small number of tests is given by Johnsen and Hovey[5] in Table VI.

TABLE VI—CELLULOSE CALCULATED AS PER CENT OF OVEN DRY WOOD

White spruce	56.48
Black spruce	50.64
Red spruce	52.95
Balsam fir	51.60
Jack pine	49.24
Hemlock	48.70
Aspen	57.52

Even within the same species it has been shown that the cellulose content varies. Johnsen and Hovey found in balsam fir that rapid growth (low density) wood contained 50.35 per cent cellulose, while slow growth (high density) wood contained 52.85 per cent cellulose. Thorbjornson[6] gives the following figures for Swedish spruce, determined from different parts of the same log:

Specific Gravity	Per Cent Cellulose
0.382	53.4
0.425	57.3
0.446	58.5

As far as the two most important pulpwoods—spruce and balsam fir—are concerned it is safe to say that spruce has a slightly higher cellulose content than balsam fir. According to these data the yield which may be expected from a given volume of solid wood will be greater with woods of high density for two reasons, (1) the greater actual weight of wood substance, (2) the somewhat greater cellulose content by weight.

[5]Johnsen and Hovey, "The Estimation of Cellulose in Wood," *Pulp and Paper Magazine*, Jan. 31, 1918.

[6]B. Thorbjornson, "Nagra synpunkter betraffande sulfitkokning" (Some Observations Regarding Sulphite Cooking), *Svensk Pap. Tid.*, p. 196, 1922.

The influence of the cellulose content on yield is much more marked when wood of different degrees of soundness are compared. It has been found by Acree[7] that the cellulose content may be decreased by as much as 28 per cent. Similar results have been obtained by J. L. Parsons[8]. While in general decay decreases the cellulose content, Parsons found that decay caused by *Trametes pini Brot.* resulted in an increase in cellulose content of 15 per cent with a decrease in lignin of 30 per cent.

Another serious result of decay is a decrease in the density of the wood. Sutermeister[9] found spruce wood which was thoroughly affected by rot but which was still quite hard and firm weighed less than 18 lb. per cubic foot of dry wood, while sound spruce weighed more than 22 lb.

Relation to the Manufacturing Process

Factors thus far considered have a bearing upon the value of the cord, particularly with regard to economy. In the following, the importance which knowledge of these factors and other factors have in the manufacturing process and on the final product will be discussed.

It is obvious that the variations in the solid content of the cord, due to the conditions of piling of wood, dimensions of logs, crookedness, and trimming, have a very great effect on the cost of production. However, these variations are eliminated as soon as the wood is in form of chips and therefore do not directly affect the capacity of the mill or the quality of the product.

Knowledge of the density of the wood is of much greater importance because it directly affects the yield and, as a result, the economy in several ways:

(1) Dense wood gives a greater weight of wood per cord.

(2) Dense wood gives a slightly higher cellulose content per unit of weight.

(3) Dense wood, consequently, increases the digester capacity, which allows (*a*) a longer cooking time at lower temperature, which results in (*b*) increased yield and a better quality of product.

These points are illustrated by the results given in Table VII obtained by experimental cooks on a semi-commercial scale.

TABLE VII—SEMI-WORKS EXPERIMENTAL COOKS

	Balsam	Spruce
Weight of absolutely dry chips from cord of peeled wood, lb	2,036	2,580
Weight of chips in digester, absolutely dry, lb	268	323
Bleach consumption, per cent	17.2	15.5
Yield of bleached pulp, per cent dry wood used	42.79	43.65
Yield bleached pulp for equal volume digester charges, lb	115	141
Absolutely dry pulp per cord peeled wood, lb	871	1,126

TABLE VIII—EXPERIMENTAL PLANT COOKS

	Month *A*	Month *B*
Weight cu ft wet chips when absolutely dry, lb	15	8.64
Absolutely dry pulp, per cu.ft digester space, lb.	3.56	3.91
Yield absolutely dry pulp, per cent of dry wood	43.7	45.2
Screenings (dry), per cent of total pulp	3.00	2.03
Cooking time, hours	12	12.5
Bleach consumption, per cent	12.7	12.0
Slowness of unbleached pulp	91.0	27.1
Strength of unbleached pulp	92	93

Actual mill data, using two different classes of wood (average figures per month) are given in Table VIII.

These experimental and mill data show how the density of the wood affects the value of a cord and the capacity of the cooking equipment.

[8]J. L. Parsons, unpublished data, Hammermill Paper Co., U. S. A.

[9]E. Sutermeister, "The Use of Rotten and Stained Wood for Making Sulphite Pulp," *Pulp and Paper Magazine*, June 22, 1922.

Another factor which affects the digester capacity is the moisture content of the chips. The higher the moisture content of the chips the heavier the chips will be and consequently the better will the chips pack in the digester. Thorbjornson[8] has shown that by using chips with an average moisture content of about 20 per cent in place of chips with a moisture content of about 40 per cent the capacity of the digester is reduced 9.5 per cent.

EFFECT OF DECAY ON YIELD

It has already been stated that the variation in cellulose content with sound wood is not great, but when rotten wood is used the cellulose content becomes a very important factor. The yield by weight, based on a number of experimental cooks, with the soda process, is shown by Sutermeister[10] to be about 30 per cent for rotten poplar wood as compared with about 41 per cent for sound poplar. For birch an even greater reduction in yield was found. Sutermeister[9], using the sulphite process with spruce wood, shows that the yield by weight is higher with rotten wood than with sound wood, but his conclusions do not seem entirely justified when it is considered that the two resulting pulps were not cooked down to anywhere near the same degree of purity; the sound wood yielding a pulp with only 0.6 per cent screenings and requiring only 17 per cent bleach, while the pulp resulting from the rotten wood had 6.6 per cent screenings and required over 30 per cent bleach. There is no reason to believe that decayed wood should give a higher yield by weight than sound wood, except in cases where the fungus has caused an increase in the cellulose content, as referred to in the case of *Trametes pini Brot.* This shows how necessary it is in investigations of this kind to specify the kind of fungus which has caused the decay of the wood, and also to compare resulting pulps on the basis of the same degree of purity. All of our experimental and mill data have shown a decided decrease in yield by weight when rotten wood is used. Also Bates[11] found a reduction in yield by weight in large-scale experiments.

Large mechanical losses will occur if wood is decayed. Kress[12] gives the following figures for loss in chipping:

	Per Cent Loss in Screening [illegible]-In. Chips
Nearly sound white spruce	5.62
Infected white spruce	13.22
Infected white spruce	15.60
Badly rotted white spruce	17.02

If wood is decayed, and especially if it is saprotten, a considerable loss also occurs in barking.

EFFECT OF DECAY ON QUALITY

The effect of decayed wood upon the quality of the pulp is not clearly evident in Sutermeister's and Bates' reports. According to Bates there is no reduction in the strength of the pulp, but his tests were made on unbeaten pulp and the difference would hardly show up at this stage, particularly when the wood is only partly decayed. Sutermeister[9] found a decided decrease in strength of pulp in the case of the rotten wood cooked by the sulphite process. With the soda process he found an increase in the strength of pulp from partly decayed birch wood, after beating in a pebble mill, while he found it impossible to make sheets of beaten soda pulp obtained from very rotten wood. Our own tests show that decayed wood has a decided influence on the beating quality as well as on the strength of the resulting pulp. Pulp obtained from rotten wood hydrates more rapidly when beaten, and with the hydration the strength increases. However, the maximum strength of the pulp is reached at an earlier stage in the beating process, after which point the strength decreases rapidly.

Such has been found to be the case, not only in experimental tests, but also in ordinary mill experience. Monthly figures from mill operation show that when a large percentage of wood was used which had been stored for 2 or 3 years and therefore was more or less affected by fungus, the strength of the pulp was considerably lower and the slowness considerably higher than when comparatively new, sound wood which came from the same locality was used. This was the case in spite of the fact that the cooking process was adjusted so as to protect the fiber of the more or less decayed wood as much as possible.

The deleterious effect of decayed wood used in the ground-wood process has been thoroughly investigated and described by Kress, Humphrey and Richards[13], and Bates[14].

SEASONING

With a raw material which may be stored for a long period before it is used in the manufacturing process, it is of interest to know what effect seasoning has upon its value. It is evident that if wood is stored so that it will deteriorate from decay its value will gradually decrease. If, however, wood is stored under proper conditions, unfavorable for the growth of fungi and so that the wood may dry out, its value for pulp will increase. As Schwalbe[15] has stated, green wood, because it is less resistant to the cooking process, gives a lower yield than seasoned wood, but he has found it possible to increase the yield from green wood materially by giving it a milder treatment. It has also been found in mill operation that seasoned wood gives a higher yield and a stronger fiber than green wood. During the period of storage the moisture content of the wood decreases, which is an advantage, since the moisture in the chips results in a direct dilution of the cooking liquor. However, if the wood is too dry, the penetration of the acid is much slower and more time is required to bring the digester up to the desired temperature and pressure, necessitating either a longer total cooking time or a higher temperature. Schwalbe found that the penetration period of very dry wood could be materially decreased by pretreating the chips with steam or with waste liquor.

Another objection to the use of green wood is the difficulty which is experienced in the manufacturing process due to pitch. It is generally known that the troublesome pitch-forming substances in the wood decrease during storage.

The most important of the factors which influence the consumption of wood per ton of pulp or the yield of pulp per cord, the density and soundness, are also the factors which influence the quality the most. In most cases the low-density wood and the infected wood

[13] Kress, Humphrey and Richards, "Some Observations of the Deterioration of Wood and Wood Pulps," *Paper Industry*, October, 1919.

[14] J. S. Bates, Grinding Tests of Average, Infected and Sound Pulpwood," *Pulp and Paper Magazine*, June 30, 1921.

[15] C. G. Schwalbe "Holzzellstoffkochung, inbesondere die Sulfitzellstoffkochung," (Pulp Cooking, with Special Reference to Sulphite), *Zellstoff u. Papier*, April 1, 1921

are cooked in mixture with sound wood of high density and the cooking process is adjusted to the sound wood. All the undesirable effects of low-density wood and decayed wood are therefore experienced—low yield, low strength and high slowness. If, however, the wood could be sorted according to its qualities, soundness, density, seasoning, etc., it would be possible to adjust the cooking process to some extent for the various grades. To maintain the production of the mill with low-density wood and with decayed wood the cooking time must be shortened by using a higher temperature. With this kind of wood high temperatures should be avoided.

It is, in many cases, possible to do so by shortening the penetration period of the cooking process, because wood of low density and decayed wood are more rapidly penetrated by the acid. A few experiments were made in order to determine how the penetration is affected by these factors. The results, which were obtained by placing disks of wood in a small digester with cooking acid of 6.18 per cent total SO_2 and 1.03 per cent combined SO_2, and bringing the temperature gradually up to 100 deg. C. in 2½ hours, keeping the temperature at this point for ½ hour, give an indication of the comparative penetrability.

TABLE IX. PENETRATION RATIO BASED ON SLOW GROWTH SPRUCE EQUAL TO 100

	Rings Per In.	Wt. Per Cu.Ft.	Penetration Ratio
Slow spruce	28	28.6	100
Rapid spruce	9	23.2	180
Slow balsam	58	22.2	215
Rapid balsam	7	18.6	350
Spruce partly decayed by *Lenzites sepiaria*		22.0	900
Spruce badly decayed by *Trametes pini*		14.0	1,500

The question of proper methods of storing pulpwood has been often discussed. It will only be mentioned here that best seasoning conditions allowing a minimum amount of decay are secured when logs are peeled or barked and then stored in such a way that good circulation of air is always maintained throughout the piles.

It has been attempted in this discussion to point out some of the important factors which influence the economy and quality in the production of pulp and paper from wood, with the object of drawing more attention to this most important raw material. It is hoped that the pointing out of the factors which so greatly influence yield and quality will result in the establishment of methods of measuring and testing wood which will be of great value in the intelligent purchase and handling of wood and which will explain variations in yield and quality hitherto not full accounted for.

Attendance at Engineering Schools

The United States Bureau of Education has obtained the following figures for attendance at engineering schools for the current year. A few of the smaller engineering schools have not reported:

Attendance for 1921-22	
Freshmen and sophomores	32,178
Juniors	11,446
Seniors	8,520
Corresponding enrollment for 1922-23	
Freshmen and sophomores	29,952
Juniors	10,383
Seniors	9,571
Total for 1921-22	52,144
Total for 1922-23	49,906
Decrease for the current year	2,238

It seems that the engineering schools have reached their maximum attendance for the present. This attendance is probably limited by the schools' facilities.

Manufacture of Soap in 1921

The Department of Commerce announces that reports made to the Bureau of Census show that production by establishments engaged primarily in the manufacture of soap amounted to $240,116,000 in 1921, as compared with $316,740,000 in 1919, a decrease of 24.2 per cent in value of products. In addition soap products to the value of $21,140,000 were produced in 1919 by establishments classified in other industries; corresponding figures for 1921 are not yet available.

The statistics for 1921 and 1919 are summarized in the following statement. The figures for 1921 are preliminary and subject to such change and correction as may be found necessary upon further examination of the original reports.

	1921*	1919*	Per Cent of Decrease
Number of establishments	283	279	...
Persons engaged	23,022	28,919	20.4
Proprietors and firm members	103	183	43.7
Salaried employees	6,361	8,300	23.4
Wage earners (average number)	16,558	20,436	19.0
Salaries and wages	$32,566,000	$35,400,000	8.0
Salaries	13,701,000	14,172,000	3.3
Wages	18,865,000	21,228,000	11.1
Paid for contract work	614,000	640,000	4.0
Cost of materials	150,356,000	238,519,000	37.0
Value of products	240,116,000	316,740,000	24.2
Value added by manufacture †	89,760,000	78,221,000	14.8‡

* Statistics for establishments having production valued at less than $5,000 are not included in the figures for 1921. 69 establishments of this class reported 34 wage earners and products aggregating $181,800 in value. For 1919, however, data for 69 establishments of this class, reporting 32 wage earners and products valued at $130,100, are included in the figures with exception of the item "number of establishments." † Denotes increase. ‡ Value of products less cost of materials.

Detailed statistics of products for the years 1921 and 1919 are given in the following table, though figures for soap and associated products produced as subsidiary products by establishments in other industries, aggregating $21,140,000 in 1919, are not at present available for 1921; hence all items are not actually comparable.

	1921	1919

X-Ray Examination of Steel Castings

It Is Possible to Locate $\frac{1}{16}$-In. Flaws in Steel 3 In. Thick With a 30-Minute Exposure From Commercial X-Ray Tubes—Correspondingly Smaller Defects Can Be Likewise Revealed in Thinner Sections

By H. H. Lester, Ph.D.
Metallurgical Laboratory, Watertown Arsenal

THE X-ray examination of castings promises to become one of the important methods of testing in foundry practice. It is important to know within what limits the method is applicable and to know the factors that determine those limits. Experiments recently conducted at Watertown Arsenal have been concerned with the practical limits and working equations in metal radiography.

Probably an impression is general that the utility of the X-ray in revealing hidden defects is quite limited, owing to the relative opacity of metal. While it is easy to radiograph a man's pelvis, measuring perhaps 12 in. side to side, a "twenty-two" bullet produces a dense shadow. Therefore we find *Chemical & Metallurgical Engineering* stating in an editorial (Feb. 15, 1922) entitled "X-Ray for Routine Testing" that the enormous difficulties seem to limit the use of radiography to moderate sections of metals of low atomic weight. Furthermore, Circular 113 of the Bureau of Standards, on "Structure and Related Properties of Metals," states that "an examination by means of X-rays is often of value if the specimen is not too large. . . . Specimens of steel to be examined by this means should not exceed ½ in. in thickness."

In contradistinction to these accepted limitations, we have found at Watertown Arsenal that the limit of penetrability based on 30-minute exposure with commercial apparatus is approximately 3 in. of steel! Anticipating the subject somewhat, Figs. 1, 2 and 3 show what has been done with relatively heavy castings to be made for air bombs. The pattern was made up and an experimental casting poured. This was sent in to the laboratory for radiographing before the risers were cut off. Fig. 1 shows the casting as we received it; it weighed about 400 lb. Radiographs were made through various points marked in chalk on the casting and prints of these, properly indicated, were furnished to the foundry. No defects of importance appeared except in the section through the nose. Fig. 2 is a print of a film placed horizontally inside the shell and exposed to rays traveling along the axis of the casting through slightly over 2 in. of metal. The three dark areas are shadows of the columnar risers. It was obvious that the risers were not feeding properly, and a change in the design of these remedied the difficulty. The casting was later cut up for study, and Fig. 3 is a photograph showing some of the holes represented by the spots shown on Fig. 2.

FIG. 1—400-LB. AIR BOMB CASTING TO BE RADIOGRAPHED

It may be objected that the information given by the X-ray might have been found by merely sawing up the casting. Even so, *complete* information is given by the X-ray far quicker and cheaper. It is no small matter to cut up heavy steel sections. Furthermore, the X-ray is of especial value in assuring oneself than an unsawed casting is sound in its vital parts. Thus sample castings are completely radiographed at the arsenal to make sure they are free from internal defects.

The questions that naturally come up for solution are: How should the exposure vary with the thickness? What is the limiting thickness of metal that may be radiographed with existing apparatus? What is the magnitude of the faults which gives certain markings on the plate? What is the limiting size of fault that may be detected under practical conditions?

With regard to the first question, How should the exposure vary with the thickness? It is possible to develop certain mathematical equations showing the relationships between the several variables involved. This work is outlined in the appendix. Practical application of theory is hampered by the fact that fluorescent screens are ordinarily

FIG. 2—RADIOGRAPH OF NOSE, SHOWING MANY BLOWHOLES. REDUCED ONE HALF

used to intensify the direct effect of the ray, and these screens deteriorate with use. Thus a photographic plate or film—which is covered by an emulsion sensitive to X-ray impact as well as to light rays—is covered front and rear by a screen impregnated with salts which visibly glow when struck by X-rays. Thus the photographic effect recorded is that due to the direct action of the rays plus that due to the fluorescence of the screens. The latter effect may amount to fifteen times the former.

In order to get experimental curves showing relation of exposure to thickness, an echelon was made of eight pieces of transformer iron 0.03 in. thick and differing in length by ½-in. steps; the pile varied from 0.03 to 0.24 in. thick, by eight equal steps. A number of steel strips 8 in. long and of various thicknesses were then prepared, stacked up

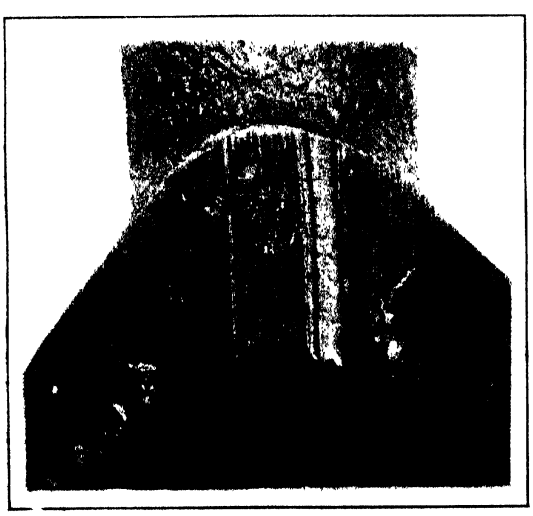

FIG. 3—CONDITION OF NOSE WHEN SAWED APART. CASTING IS 2 INCHES THICK

and the echelon placed on top of the pile, whereupon the whole was radiographed. Patterson "cleanable" intensifying screens were used. These screens were new and had their maximum sensitiveness. A series of negatives was made at varying times—other conditions being constant—and one picked out which showed clear or nearly clear under the thick end of the echelon and a regular graduation of density under the other steps. One film was selected and step 4 of this was arbitrarily taken as a standard for judging other negatives. Then a series of films was taken through piles of different height, and all of them were compared with the standard. The thickness of steel plus the thickness of transformer iron under the step that exactly matched the standard density was plotted against the corresponding "exposure." ("Exposure" means time of exposure multiplied by the current flowing through the Coolidge tube.)

Results of individual determinations are shown by dots on Fig. 4. As shown, two series of negatives were made, one when 100 kv. potential was impressed on the Coolidge tube, and the other under 195 kv. Curves *A* and *B* are figured according to the theory, with constants so chosen as to fit the observed values as closely as possible. A family of similar curves is also drawn,

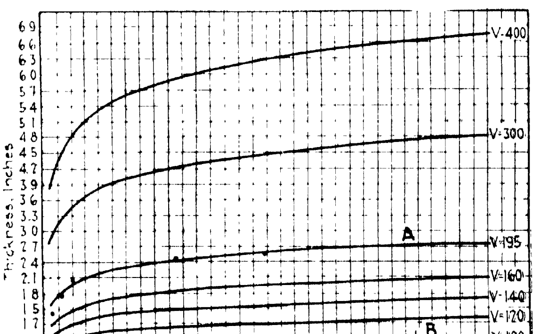

FIG. 4—RELATION BETWEEN THICKNESS OF STEEL PENETRATED, TIME OF EXPOSURE AND VOLTAGE AND CURRENT THROUGH X-RAY TUBE

checked by experiment on voltages up to 230 kv., and assumed by extrapolation for higher.

The curves shown in Fig. 4 are practical working curves and are used in our laboratory as a guide to the necessary exposure for a given specimen. Actual exposures are plotted rather than logarithm of exposure because of greater convenience in use. The tube which we use can be operated at 200 kv., then consuming 7 milliamperes of current. In order to get any work done it is necessary to limit the time for making a negative to 30 minutes. The "exposure" therefore is 30 minutes × 60 seconds × 7 milliamperes, or 12,600 milliampere-seconds. Running up the vertical ordinate corresponding to 12,600 to slightly above the curve marked V-195 gives a valve of 2.9 in. for the limit of penetrability at a distance of 17 in. from the target.

In practice we have radiographed 3.1 in. of steel with the film at a distance of 13 in. from the target, and the film was somewhat more dense than the standard used above.[1] Hence it is probable that 2.9 in. is

[1]Since the above was written we have penetrated 4.1 in. of steel, but under cond'tions of varying voltage so that it was not possible to check the equation.

fairly conservative. With a 300-kv. tube the curve indicates that we would be able to penetrate about 4.8 in. of steel, and with a 400-kv. about 6.8 in. of steel, using the same exposure (12,600).

Such tubes are needed. One of the difficulties today in metal radiography is the limitation of possible penetration. Greater penetration may be had either by increasing the transmitted radiation or by increasing the sensitiveness of the film system. To aid in the latter respects screens will undoubtedly be improved. Bulbs must be improved to take a higher potential rather than a heavier current. This fact is illustrated in Fig. 4. If we double the power consumption in a 195-kv. tube by doubling the current, we double the "exposure." But for long exposures the increase in penetration is very small indeed—the curve flattens out almost to horizontal. If, however, we double the power consumed in the bulb by doubling the potential (200 kv. to 400 kv.), the current remaining the same, we change the thickness that can be radiographed in the same exposure (12,600) from 2.9 to 6.7 in., a gain of 3.8 in.

SIZE OF CAVITIES WHICH CAN BE DETECTED

To determine the magnitude of a fault it is necessary to consider the area of the image and its relative density. If the cavity is sufficiently large, as compared to the focal spot in the X-ray tube—and sufficiently close to the film, so that definite, unblurred outlines occur, the image will be a scenographic projection of the fault. This is illustrated in diagram *D* of Fig. 5. Under these conditions, if the cavity is roughly spherical, this projection will be related to the section through the fault parallel to the film by the laws of geometry. The area of the section may be calculated from the area of the image, the distances from the target to the flaw, the distance from the target to the film, and the inclination of the film to the axis of the X-ray beam through the flaw. If the cavity is not spherical and its major diameter is inclined to the axis of the X-ray beam through the cavity, the area of a section of the cavity usually cannot be found from the area of the image given on one film. If the fault is small in comparison to the area of the focal spot in the Coolidge tube, the cavity acts like the aperture of a pinhole camera.

FIG. 6 IMAGE OF TUNGSTEN TARGET OF COOLIDGE TUBE TAKEN THROUGH A PINHOLE IN A LEAD SHEET

The "image" appearing on the developed film is the image of the focal spot of the target rather than the image of the flaw. This pinhole image depends upon the variables that would affect the image in a pinhole camera—viz., the relative distances of the film and target from the hole, the area of the hole and the area of the focal spot of the target. For cavities small enough a true image of the focal spot would occur. Such an exposure is shown in Fig. 6. This is a very sharp view of the whole target—it shows the focal spot from which most of the X-rays emanate, together with the outlines of the target and some of the supporting stem, all of which is excited to emit resonance radiation.[2]

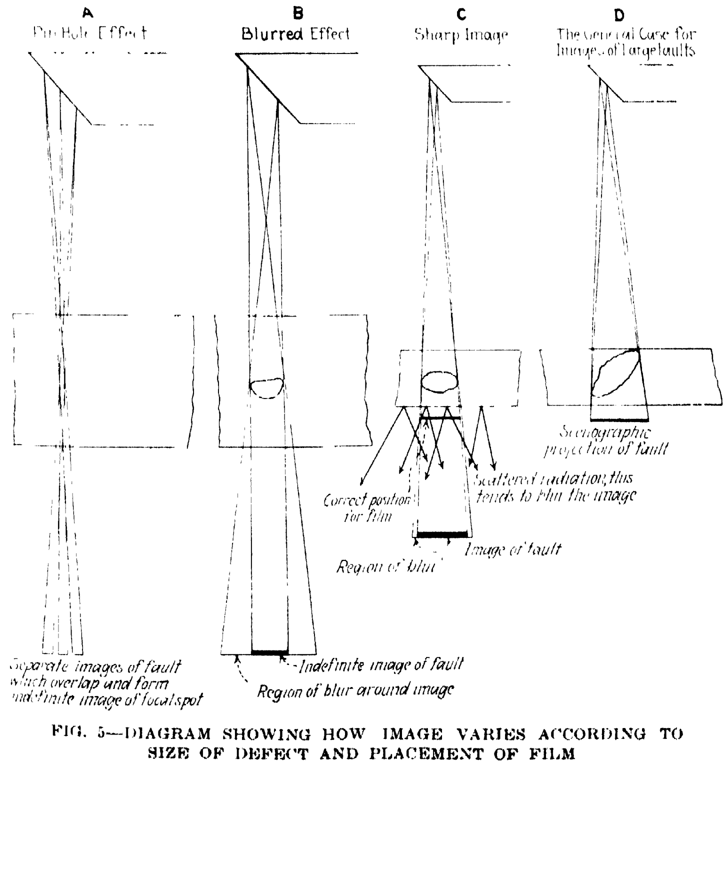

FIG. 5—DIAGRAM SHOWING HOW IMAGE VARIES ACCORDING TO SIZE OF DEFECT AND PLACEMENT OF FILM

Images produced by somewhat larger cavities would be indefinite, as shown in sketch *A* in Fig. 5. For still larger cavities the outlines of the fault would begin to appear (sketch *B*), and for cavities sufficiently large the image would present the sharply defined outline of the projection of the cavity (sketch *C*). In the case of the pure pinhole image the area of the section of the fault could not be calculated; where the outline of the cavity appears it is possible to calculate the area in some cases as outlined above. In practice most of the types of images sketched in Fig. 5 appear, sometimes all on one negative. However, a pure pinhole image of the focal spot such as shown in Fig. 6 has not been surely identified in practical exposures on steel castings.

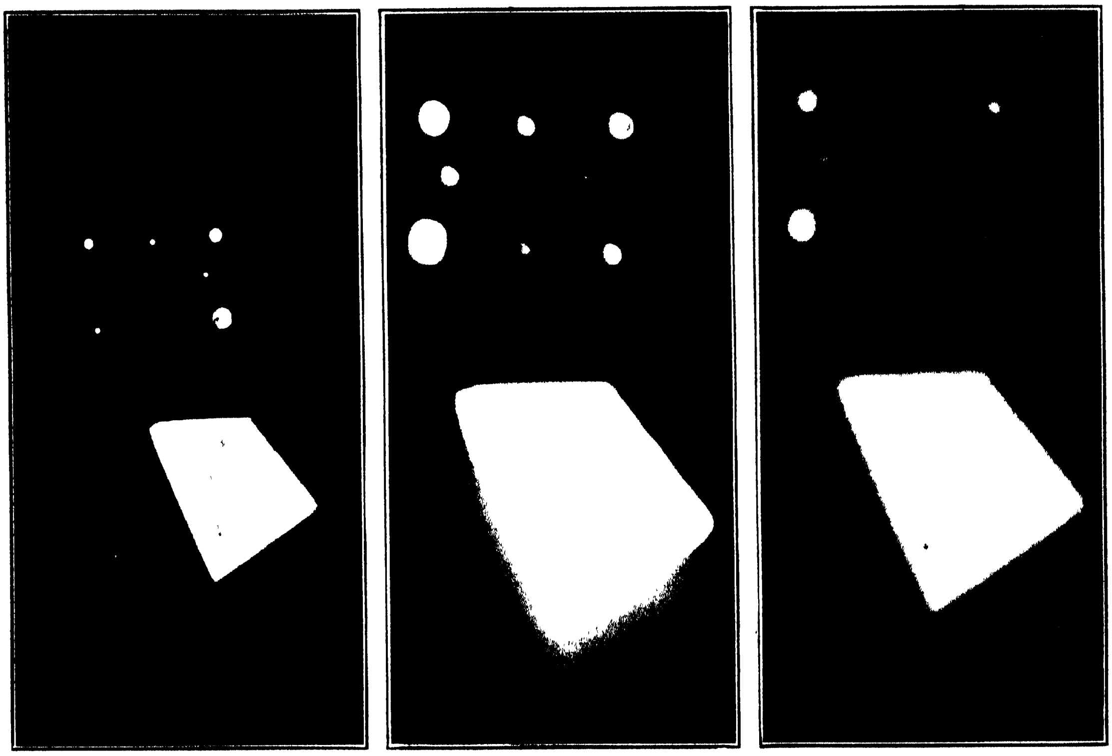
These principles may be illustrated by X-ray exposures of holes in a lead sheet. Fig 7 is the radiograph of a piece of lead sheet in which holes were drilled ranging in diameter from 0.032 up to 0.227 in. There was one large irregular hole made with a file.

[2]"X-Ray Studies," page 95. General Electric Research Laboratory, 1919. Dr. Coolidge has explained this effect as due to wandering electrons that do not hit the focal area but reach other parts of the target.

The smallest hole was carefully cleared. Some of the other small holes contained metal shreds which were purposely left so as to give the effect of irregularly shaped small holes. The film was placed 1 in. below the lead. The images appear sharp, even the metal shreds showing.

Fig. 8 represents a radiograph of the same piece of lead, but here the lead is 11½ in. away from the film. There was no metal interposed except the aluminum top of the cassette holder. In this picture the smaller holes show a distinct image of the focal spot of the target. This effect is the same for the cleared central hole and for the irregularly shaped small holes. The peculiar spiral appearance at the tiny central hole and the one at the left is not accidental—it is a correct image of the focus, and shows details lacking from the round white spot of Fig. 6. Fig. 10 shows a negative print of a film registering a focal-spot image taken through a pinhole 0.017 in. in diameter with the film 18 in. from the lead. The negatives for these show of the whole target that appears as tails below the largest drill holes and the trail of light below the large irregular hole. Fig. 9 represents a radiograph of the same lead sheet, but in this case 0.35 in. of steel was introduced just beneath the lead, and the film was 11½ in. from the lead. An attempt was made in this exposure to bring out the effect of radiation from the bottom of the steel and to illustrate the effect of the interposition of metal on definition.

A comparison of Figs. 8 and 9 shows that the relative *contrast* is less where additional metal is interposed. This is due to the fact that radiation from the bottom of the steel affects parts of the negative which formerly were completely shielded by the lead. The *definition* in Fig. 9 is, however, somewhat better, at least at the corners of the large image. The blurring effect and the "tails" caused by the characteristic radiation from the target support are missing. This radiation being less penetrating than the radiation from the focal spot, it is entirely absorbed by the iron. When Fig. 8 is com-



FIGS. 7, 8 AND 9 RADIOGRAPHS OF A PERFORATED LEAD SHEET
Fig. 7 Film 1 in. below lead. No screen. Fig. 8 Film 11½ in. below lead. No screen. Fig. 9—Film 11½ in. below lead. Screen: 0.35 in. of steel

more than is evident in the print, even though the latter has been slightly retouched. The cathode stream evidently plays on certain favored spots on the target which may be small irregularities in the surface. The stream, however, tends to describe a circle around the outer edge of the focal area and travels from the spots to the outer circle by definite spiral paths. Sometimes as many as seven spots were counted, most of which were near the center of the focal area, and from each of these there was a spiral path leading to the outer circle.

There is also evident in Fig. 8 the effect of X-rays coming from other parts of the target, shown so clearly in Fig. 6. This radiation causes the indefinite image pared with Fig. 7, a remarkable loss of definition is noted at the corners. In Fig. 7 the corners are sharp angles, in Fig. 8 they are arcs of circles; in Fig. 9 they are rounded also, but the radius of curvature is much less, so that the corners are much sharper than in Fig. 8. This rounded corner effect is due to a sharply defined band (much more evident in the negative than in the print here reproduced) located just inside the image. It follows the contour of the image except at the corners where this line makes the rounded corner effect noticed in the reproduction. In fact, this dense line is the edge that shows in Fig. 8. In the negative for Fig. 9 the line is still present but is less pronounced and it makes a much sharper turn at the corners. In

Fig. 11 the line is missing entirely. The latter figure is a negative print of a sheet of lead bent sharply around the end of a screwdriver and squeezed home with pliers. The sharp angle is faithfully reproduced.

The band causing rounded corners is undoubtedly due to X-rays reflected from lead crystals in the vertical surfaces of the holes. It travels toward the interior of the image as the film is moved away. Since the sheet of steel interposed in Fig. 9 filters out much of this scattering radiation, the band formed by the reflection of shorter wave lengths is reduced nearly to a line, and follows the contour more closely. Fig. 11 was taken through 2.35 in. of steel, which entirely absorbed the lead radiation. Therefore the edge of the image is less definitely marked due to the absence of the band, but the corners are faithfully reproduced. Another negative too faint for reproduction was taken of a V-shaped opening in a piece of lead sheet ⅛ in. thick through 3.1 in. of steel. The definition was as sharp as that illustrated in Fig. 11. We concluded that the definition remains sharp as long as the image is detectable, no matter how much metal is being penetrated, except where pinhole effects occur.

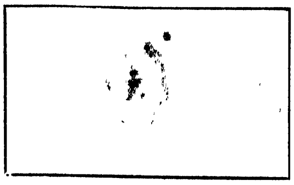


FIG. 10—PINHOLE IMAGE OF FOCAL SPOT (RETOUCHED NEGATIVE PRINT)

The magnitude of the fault in the direction of the X-ray beams—i.e., the thickness of the fault—is usually of greater importance than the sectional area. In fact, an estimate of the sectional area can often be got from the thickness of the fault and a general knowledge of blowholes and pipes, without relying on the geometric relationships sketches in Fig. 5.

However, it is difficult or impossible to arrive at definite conclusions on the thickness of a cavity from an inspection of the negative. In order to determine the thickness of the fault the relative density of the image to the density of the adjacent portion of the film must be considered. If that ratio is great—i.e., there is much contrast—the magnitude of the fault is apt to be considerable, but densitometer measurements would in most cases not give reliable data on which to compute definite measurements. The difficulty comes from the fact that the density in a photographic film is not a linear function of the exposure, as noted in equation 2 of the appendix. X-ray exposures usually fall in what is known as the "underexposed" portion of the curve. The image of a fault may fall near the bend of the curve where the slope changes rapidly, while the density of the adjacent portions of the film may come further down on a nearly straight portion. Therefore the densities of the negative may not give direct information on the size of the blowhole. If the film were exposed so that both portions of the film fell in the correct exposure region, then a linear relationship could be established that would give a definite measure of the thickness of the fault. However, this is not practicable, because it would increase the time of exposure too much.

The problem of getting a relationship between the relative densities of the image and adjacent film and the thickness of the fault is an important one. It is planned to attack the problem in this laboratory. We judge the magnitude of the fault by the density of the image at present, but we realize that our judgment is more or less a guess.

The value of the radiographic method as a detector of flaws can be determined more accurately by relatively simple experiments. Obviously the relative density of the image will depend upon the relative thickness of metal traversed by the radiation in passing through the region in which the fault occurs and the region adjacent to this. If we adjust the exposure so that there is no visible density in the developed negative in the region adjacent to the image and then reduce the magnitude of the experimental flaw until its image is barely perceptible, we then have determined the limit of magnitude of flaw that can be detected. Experiments of this sort showed that with a steel plate ½ in. thick a difference of 0.0005 in. could be readily detected. This amounts to a flaw thickness of one part in one thousand.

However, this experiment is misleading. If instead of having one part of the film clear and apparently unaffected by the rays, both parts are exposed "(underexposed" in the sense of equation 2 in the appendix), then the detection of the faint image is more difficult. In order to test this more general case a steel plate 8 in. long was ground so as to form a wedge 0.5 in. thick at one end and 0.492 in. thick at the other. This wedge was divided into 1-in. sections by lead strips and radiographed so that the negative under the thick end was nearly clear. The rest of the negative showed bands of increasing density. Other negatives were made with the steel built up to various thicknesses by the addition of parallel plates. Thus it was possible to distinguish between bands 2 and 4 with the steel ½ in. thick. With the steel 1 in. thick the difference between bands 2 and 7 could be detected. When the total steel was 1.2 in. thick, no difference could be found between one end of the film and the other.

These negatives show contrasts too faint for reproduction, or even for printing, but with good illumination the differences in density can be detected in the negative. Such experiments indicated that differences in metal thickness of about 5 parts in 1,000 could be detected in this way.

Still the test is hardly fair, because it is easier to detect slight differences in large areas where the total light coming to the eye might be materially different, even though the illumination of the two areas is nearly the same. It is much more difficult to detect small differences when one area is much greater than the other. These circumstances obtain, of course, when radiographing a small defect in a large section. It is possible, however, to use an illuminator and an exploring screen —that is, a screen with a hole in it so as to inclose the image to be detected against a minimum of adjacent

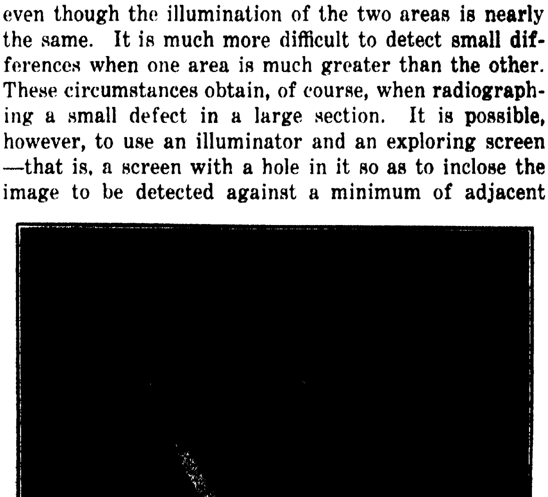

FIG. 11—TWO PIECES OF LEAD EXPOSED THROUGH 2.35 IN. OF STEEL. FILM 4 IN. FROM LEAD

film. If this is done it should be possible to detect flaws of the ordinary magnitude indicated above. In order to hunt small images in a large field, test specimens were prepared by drilling holes of various diameters in a sheet of transformer iron 0.015 in. thick.

Other sheets 0.03 in. thick were similarly prepared. One of these was placed on a stack of steel plates and the whole radiographed. Using the 0.015-in. plate the smallest hole (0.03 in. in diameter) disappeared when shooting rays through 0.9 in.; the largest hole, 0.25 in., was still visible at 1.1 in. Using the 0.3-in. plate the holes disappeared at about 1.8 in., the smallest hole disappearing certainly at 1.6 in.

These experiments would place the limit of detectability for this particular case at somewhere near 15 parts in 1,000. That is, a blowhole 0.04 in. in diameter in a piece of steel 2.5 in. thick should be detectable under ordinary exposures of 10,000 milliampere-seconds. This is the upper limit. It is probably better to regard the limit for practical work at about 2 per cent.

The surface markings on a casting are often of greater magnitude than this. In such cases doubt may arise as to whether a dense spot in a negative is a surface mark or a hidden flaw. Comparison with the original casting may remove the doubt, but in important cases we use a stereoscope. Stereoscopic negatives are taken by making two exposures under as nearly identical conditions as possible, except that the X-ray tube is displaced the distance center to center of the observer's eyes. These two negatives, properly mounted, viewed in a stereoscope enable the operator to distinguish very definitely between the surface markings and the inner flaws, because they then give the illusion of depth—the defect appears in its proper position in space. This method gives the operator definite results with a little practice. In fact, the stereoscope greatly extends the usefulness of the radiographic method, and we regard it essential equipment of the laboratory.

The radiographic process as used in foundry testing is most useful to detect the existence of flaws; it is only in special cases that the exact outline of the flaw must be known. Then the sharpness of definition is of chief importance. The effect of secondary radiation is sometimes spoken of as an effect that tends to destroy definition.

Secondary radiation is in some ways analogous to the effect of light shining in a fog. The water particles reflect and refract the light in all directions so that all objects are seen in uncertain outline. If the photographic films were actually within the body of the metallic substance, the same shadowy outlines would be produced. Since the metal and film are separated, the scattering rays act differently from light in a fog principally because X-rays are much more nearly monochromatic than ordinary sunlight, which, as we all know, is a mixture of the rainbow hues. Scattered X-radiation therefore may be thought of as monochromatic, its wave-length depending upon the characteristic frequencies of the metallic atoms. This radiation is most easily absorbed by the neighboring atoms so that most of the scattered radiation is absorbed by the metal itself. There is a certain amount escaping from a thin layer next to the photographic plate. This is indicated in sketch C of Fig. 5. If, as usually happens, the film is perpendicular to the axis of the X-ray beam, that portion of the scattered radiation that originates within the metal will have its components selectively absorbed so that the emergent components will be greatest in the direction of the radiation that proceeds from the target. This part of the scattered radiation assists in forming the image. The part that originated at or near the surface will proceed in all directions and will tend to fog the film.

That portion of the incident radiation that is transmitted directly through the metal will be highly monochromatic when it emerges (due to the filtering action of the metal) and its wave-length depends on the voltage across the bulb. Furthermore, its wave-length is very different from the wave-length of the scattered radiation and will probably have a different photographic effect. Hence even when photographing through thick metal a sharp image of the flaw should appear upon a background of general fog, except where the pinhole effect comes in. This would destroy the definition even when photographing with ordinary light.

Summary

1. Our experiments in radiographing steel indicate that for material at a fixed distance from the target of the X-ray bulb and with the use of intensifying screens, the relationship between thickness, potential and exposure may be expressed by an equation of the form

$$y = (AV - B)\log x$$

where y is the thickness in inches, V is the potential in kilovolts, x is exposure expressed as the product of the current through the bulb in milliamperes multiplied by the exposure time in seconds. A and B are constants for our particular machine and with steel at a distance of 17 in. from the target. $A = 0.0048$ and $B = 0.26$.

2. The limit of penetrability based on 30 minutes exposure with apparatus commercially available is placed at approximately 3 in. of steel.

3. The magnitude of a fault may be judged from the area and relative density of the image only within rather indefinite limits.

4. For thickness of metal near the limit of penetrability a flaw approximately 2 per cent of the thickness of the metal may be detected.

5. Where the flaw is sufficiently large or sufficiently close to the film so that the pinhole effect is not important, the definition of the image remains sharp as long as the image is visually detectable in the negative.

Appendix

Mathematical Relationships

The law of absorption of X-rays is well known. If monochromatic radiation is incident upon material of given density, each successive increment of thickness absorbs an equal fraction of the radiation incident upon the sheet of material represented by that increment.[1] This gives rise to the equation:

$$\rho = \frac{2.3}{y}(\log I_0 - \log I)$$

where ρ is the linear absorption coefficient, y is the thickness of material, I_0 is the incident radiation and I is the radiation transmitted. It is known that the coefficient ρ is proportional to the wave-length. The wave-length of the radiation is inversely proportional to the potential applied to the tube so that the equation could be written:

$$y = VK(\log I_0 - \log I) \qquad (1)$$

where V represents the potential applied to the bulb and K is a constant depending upon the material, units employed, etc. The absorption law has been verified by ionization methods and also by the direct action of the transmitted radiation on a photographic plate. In practice the photographic film is used with intensifying screens. The fluorescence of the screen varies with the wave length of the exciting radiation. This variation[2] makes it difficult to apply equation (1) where the density of the film is used to judge the exposure.

In equation (1) I and I_0 represent

[1] Kaye, "X-Rays," p. 100 (1914).

[2] Millard B. Hodgson, "The Physical Characteristics of X-Ray Fluorescent Intensifying Screens," *Phys. Rev.*, vol. 12, No. 6, p. 431 (1918).

intensities. The photographic plate responds to intensity times time or total radiation. However, since I_o and I occur as a ratio the equation may just as well be written in terms of the total radiation received by the material and plate respectively during time of exposure. The radiation that affects the plate is IT. The negative density is related to this IT term in accordance with the well-known Hurter and Driffield equation for photographic density,

$$D = A + B \log E \qquad (2)$$

where D is the density of silver deposit, E is exposure and is represented by IT, A and B are constants. If we, by trial, make the negatives all of the same density then IT should be a constant, provided the fluorescence of the screen does not change. Equation (2) may therefore be written

$$y = K'V(\log I_oT - A) = C'' \log x - \frac{A'}{V} = \text{constant} \qquad (3)$$

where x is put for I_oT.

The intensity of the X-ray beam is proportional to the current through the tube. Hence x may be expressed as the product of the tube current multiplied by the time of exposure. For want of a more convenient expression we have conformed to the usual practice and called this quantity the "exposure." It is the exposure to which the material rather than the film is subjected.

Equation (3) was checked by making a series of exposures of a pile of steel strips placed en echelon, as outlined above. "Exposure" for a given density on the film was then plotted against thickness of iron. The experimental values plotted along the 195- and 100-kv. curves (Fig. 4) were obtained in this way. It was found that in each case the values could be represented by an equation of the form of equation (3).

We were not successful in the attempt to fit the experimental data to a *family* of curves of the form $y = KV(\log x - A)$, since K and A both vary with V. For instance, the 195- and the 100-kv. curves are represented by the equations

$$y = 0.00343V(\log x - 0.02) \text{ and}$$
$$y = 0.00195V(\log x - 0.45) \qquad (4)$$

respectively. This fit is not to be expected if the variation of the screen fluorescence with V affects the values of I. It is evident, however, that the experimental values represented by equations (4) may be represented nearly as well by equations of the form:

$$y = C \log x \qquad (5)$$

where C is a parameter depending on V. For instance, equations (4) may be represented within the limits of experimental error by equations

$$y = 0.68 \log x$$
$$y = 0.22 \log x \qquad (6)$$

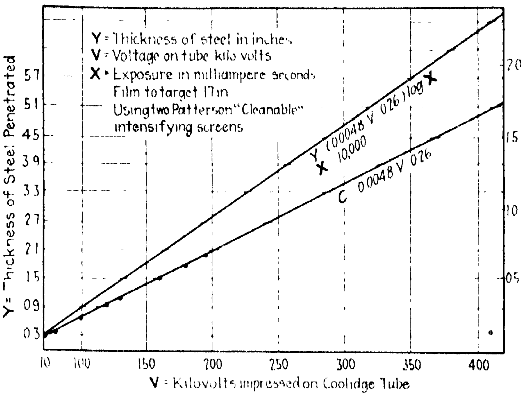

FIG. 12—THICKNESS OF METAL PENETRATED BY EXPOSURES OF 10,000 MILLIAMPERE-SECONDS

Assuming equation (5) to be the type of equation best fitted for the curves, experimental values for C were obtained for a series of values of V and these were plotted against V. The points fell very accurately on a straight line between V equal 80 and V equal 195 kv. This line, shown in Fig. 5, curve A, has for its equation

$$C = 0.0048V - 0.26 \qquad (7)$$

Substituting this value in equation (5) gives the relationship between potential, thickness, and exposure in the following equation:

$$y = (0.0048V - 0.26) \log x \qquad (8)$$

where y is expressed in inches, V in kilovolts and x in milliampere-seconds. Equations 7 and 8 are plotted in Fig. 12.

In obtaining equation (8) the film was kept at a fixed distance of 17 in. from the target. The exposure varies with the distance according to the inverse square law. The interposition of absorbing material in X-ray exposure is analogous to the interposition of an absorbing screen of sectored disk in optical pyrometry: the effect is to change the apparent intensity of the source of illumination. The effective illumination on the film system is inversely proportional to the square of the distance from the target for the transmitted radiation, and it is sufficiently accurate for practical work to apply the same law to the exposure as we have used it in the foregoing discussion.

Equation (8) is empirical and does not hold for small values of V. This may be due to peculiarities of the screens or to the fact that for values of V above 100 kv. the transmitted radiation plays the more important part in the photographic action. This radiation, is, however, not all the radiation that affects the film. The fluorescent radiation from the bottom layer of the steel also reaches the film and probably becomes relatively more important for smaller values of V down to about 10 kv., where the K absorption frequency for iron occurs. We have tested the relation down to 80 kv. with satisfactory results. It is probable that the relation holds for values greater than 200 kv., which is the upper limit of potentials possible with our machine. The curves for 300 kv. and 400 kv. in Fig. 4 are derived from values of C obtained by exterpolating equation (7). If this is permissible, these curves give us a means of estimating the bulb potentials that will be necessary for going through greater thicknesses of material than is now possible with present equipment.

Sponge Iron

Work has been conducted for some time past at the Seattle station of the Bureau of Mines hoping to develop a method by which sponge iron can be made by using low-grade coals and iron ore in a direct-fired, rotary kiln. The sponge iron will be useful in the production of foundry iron, steel, and for the precipitation of copper from solutions resulting from leaching operations.

Tests will now be made in a small furnace that will treat about half a ton of ore per day. Attempts will be made to increase the rate of reduction of the iron oxide by adjusting the operating conditions of the furnace and the conditions of the charge. Concentration studies will be made on a product with a view to obtaining a high-grade sponge iron suitable for melting in an electric furnace, or for use in precipitating copper from solution.

Melting this sponge to foundry iron involves its carburization. Consequently the latter reaction has been studied on a laboratory scale and is to be continued on a commercial scale, using some of the local commercial electric furnaces and foundry cupolas. A study of the mechanism of carburization and of the causes of graphitization will be conducted in the laboratory. After the above studies have been completed, the conditions determined therein will be applied to the melting of sponge iron.

Steel Treaters to Publish Data Sheets

As a service to its members, the American Society for Steel Treating plans to prepare, publish and distribute, in loose-leaf form, data sheets relating to steel treating. These sheets will consist of tables, charts and pertinent information useful to the practicing metallurgist and heat treater.

It is proposed that the A.S.S.T. Handbook will have the same relationship to the steel treating industry as the S.A.E. Handbook to the automotive industry and Kent's Handbook to the engineering industry. D. K. Bullens, author of "Steel and Its Heat-Treatment," will be the editor, and the members of the society have been circularized asking them to send in suggestions concerning useful data to be included.

BY WELLINGTON GUSTIN
Of the Chicago Bar

Decision Upholding Validity of Tungsten Filament Patents Brings Out Points on Foreign Process Patents

In the infringement suit brought by the General Electric Co. against F. Alexander and another involving the Just and Hanaman patent, No. 1,018,502 and the Langmuir patent, No. 1,180,159, the United States Circuit Court of Appeals has affirmed the decree of the District Court in favor of the plaintiff holding these patents valid.

These patents have been a great deal in the courts and the trial court gave the litigants the widest opportunity to put forward almost any conceivable fact, experiment or theory, with any and all defenses thereto, relating to validity or infringement, in order that litigation as to the validity of these patents should some day come to an end one way or the other.

The court finds that there is not a shred of merit to the attack on the validity of the Langmuir patent. It was contended that the American Sinding-Larsen patent, No. 672,019, invalidates the Langmuir patent. The court found that the Sinding-Larsen lamps have never been used, because the theory was wholly wrong. (277 Fed., 290.)

ARGUMENTS AGAINST VALIDITY OF JUST AND HANAMAN PATENT

The defendants were making and selling tungsten nitrogen lamps substantially identical with those made and sold by plaintiff under the asserted protection of the aforesaid patents and the Coolidge patent. The defenses urged against the validity of the Just and Hanaman patents were:

(1) That the same patentees obtained a German patent, 154,262, valid from April 15,1903, for substantially the same invention as is revealed by their patent in suit applied for July 6, 1905; wherefore the patent at bar is invalid under a federal statute (Rev. Statutes, section 4,887) requiring foreign patents to be registered in this country within 2 years from the time they are obtained in another country.

(2) There is no infringement, because defendant's filaments contain an extremely small quantity of thoria, which prevents said filaments being the "pure, coherent, or homogeneous" tungsten filaments of Just and Hanaman. In point of fact defendant's filaments are admittedly made in the manner of Coolidge, and contain thoria for the reason and purposes set forth in Coolidge's disclosure.

INOPERATIVE FOREIGN PROCESS PATENT CANNOT DEFEAT PRODUCT PATENT

Passing on the first defense set out above, the court says the defense of invalidity under section 4,887 puts a heavy burden on a defendant. The various amendments to that section have not changed the truth of Judge Putnam's statement in a former case, 183 Fed., 828, that the act applies only to cases where the inventions actually claimed in the foreign and domestic patents are identical. It is not sufficient that the foreign patent may disclose the invention of the later United States patent where it is not therein claimed.

Again it points out that the claim of the German patent is for a process which it says is wholly inoperative, in that it cannot produce the product covered by the patent in suit. The essential reason for this conclusion is that doing what the German patent calls upon one to do will never replace carbon or tungsten. The process rests upon the theory of replacement, and that theory has no substratum of fact.

The German patent being for a process and the American patent for a product, the court says it is true that, if the only use of the process is to make the product, such foreign process patents would and should affect an attempt to get American protection for the product. But that is not true in this case, the court finds. The German process patent will not make anybody's incandescent lamp filament, and especially will it not make the product of the patent in suit. Therefore the court holds that in no sense are the two patents for the same invention, whether one regards the proved facts or the language of disclosure and claims.

USE OF THORIA DOES NOT PREVENT INFRINGEMENT

Now the defendants admitted the use of Coolidge's thoria-containing filament; but as they were not being sued on the Coolidge patent they could not infringe here. A former decision in the Laco-Phillips case, 233 Fed., 96, specifically held that a Coolidge drawn filament infringed the Just and Hanaman patent, although it was an improvement of such striking nature that it completely drove all other tungsten filaments from the market.

Now the court points out that while impairment of function is no defense to infringement and improvement of function is oftentimes patentable matter of a very valuable kind, if the functioning of a patent is substantially appropriated by substantially using the patented means, infringement always exists. The object of all makers of light filaments is to get the best light, and what at present makes the tungsten filament the best light-giving means is pure, cohering and homogeneous tungsten. Tungsten of that kind is functioning just the same with or without the mechanical thoria stiffener. This is true, whether the slender thread of incandescence is made by Just and Hanaman, or by Coolidge, or by the defendants.

IMPREGNABLE INVENTION, SAYS COURT

Defendant Alexander and one Fabian were once partners trading as Alpha Electric Laboratories. This concern sold infringing lamps, whereupon this action was brought against the partners trading as aforesaid. Subsequently plaintiff learned that, before the bill was filed, the business was incorporated as Alpha Laboratories, Inc., at which time Alexander bought out Fabian and became the owner of all the shares in the new company. The corporation continued to do the same business, making and selling the infringing lamp. Suit was dismissed as to Fabian, but the decree against both the corporation and against Alexander personally was upheld.

The court says that "notwithstanding the ingenuity and ability with which the Just and Hanaman American patent has been attacked, it remains where it was and where it should be—the embodiment of an impregnable invention of the highest order."

Elastic Column Dynamometer for Hardness Testing

BY HERMAN A. HOLZ

A NUMBER of devices have been developed during recent years to measure the load in small static testing machines used in hardness testing by the ball or cone methods of Brinell or Ludwik.

The original Alpha machine made in Sweden and several American-made Brinell machines make use of a spring manometer gage which is checked either against a piston loaded with weights or against another spring manometer gage. The spring manometer, suffering from changes in the spring and temperature variations, is by no means a satisfactory instrument of precision. Amsler's hardness (Brinell and Ludwik) testing press utilizes the well known pendulum dynamometer for measuring the load on the indenting tool. It utilizes what is undoubtedly the most accurate and constant apparatus known to modern science for measuring the load. However, it is quite expensive, and is difficult to adjust or modify to meet a wide variety of special problems encountered in practice.

Some of the other schemes used for determining the load in hardness-testing apparatus are the deformation of calibrated springs (Guillery), the deformation of the frame of the testing machine itself (Derihon), the balancing of weights by levers (Avery, Herbert, Riehle, etc.). Levers and knife edges subjected to heavy stresses, jerks, sudden releases and other slowly but progressively deteriorating influences are by no means ideal elements in the construction of testing machinery. Even in the large tensile machines, the lever type machines are being rapidly superseded by those machines which do not contain any knife edges.

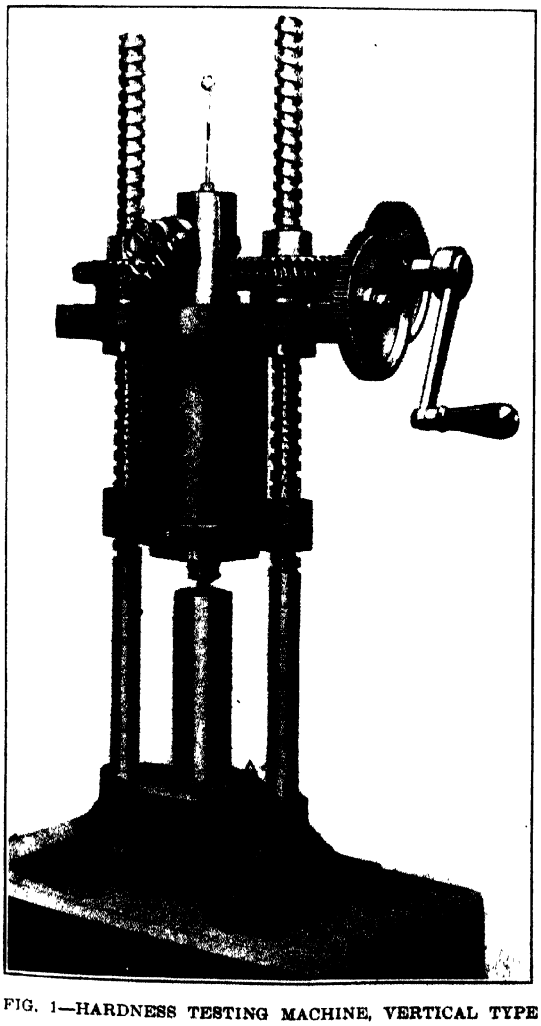

FIG. 1—HARDNESS TESTING MACHINE, VERTICAL TYPE

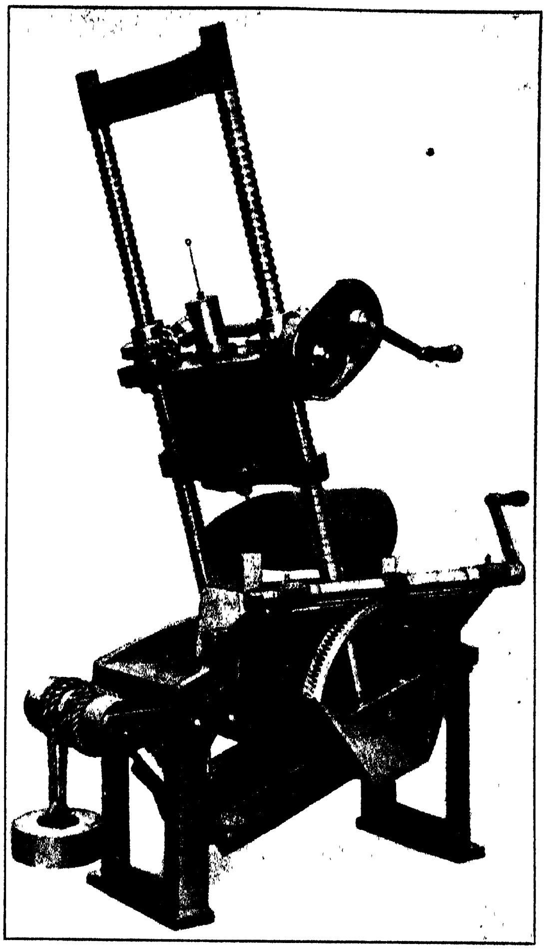

FIG. 2—HARDNESS TESTING MACHINE, SWINGING TYPE

Methods of *applying* the load do not vary so widely. In nearly every design a small hydraulic pump builds up pressure within a cylinder, and this pressure is transmitted to the testing point by means of closely fitting pistons and rods. Small hydraulic machines are not altogether suitable for continuous use in places where dust and soot are apt to get into valves, such as often occurs in heat-treating shops. The elastic column dynamometer described below imposes a load by a train of gears and screws, so that we now have practical, accurate and rugged instruments for measuring the load on hardness testers in which nothing can get out of order and that can be operated satisfactorily and correctly by anybody, in any position and at any range.

The principle used by Dr. Alfred J. Amsler in designing this dynamometer is illustrated in Fig. 3. The apparatus forms the upper part of a press; the material under test is pressed against plate *B* with a load *P*. The reaction is taken up by shoulders *A*, which are

securely connected to the base of the machine. The total load which acts on the test piece is transmitted by means of columns *C* from the compression plate *B* to the shoulders *A*. Under compression these columns shorten a very small amount, their deformation being always proportional to the load which they transmit, since they are loaded far below their elastic limit.

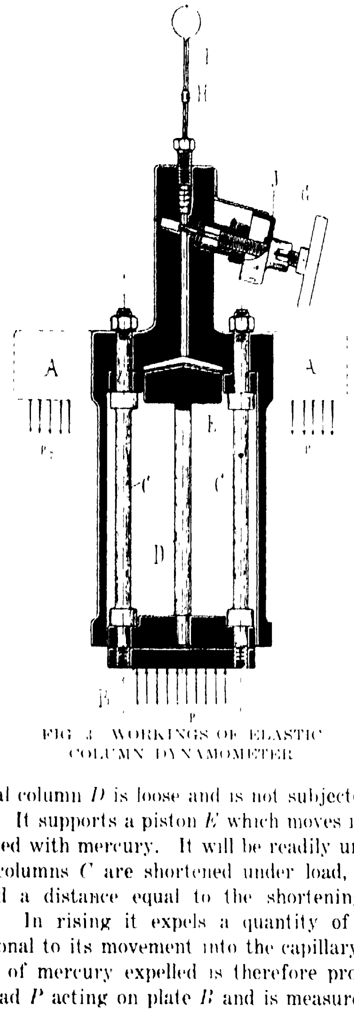

FIG. 3—WORKINGS OF ELASTIC COLUMN DYNAMOMETER

Central column *D* is loose and is not subjected to any stresses. It supports a piston *E* which moves in a small space filled with mercury. It will be readily understood that if columns *C* are shortened under load, piston *E* is raised a distance equal to the shortening of the columns. In rising it expels a quantity of mercury proportional to its movement into the capillary *F*. The quantity of mercury expelled is therefore proportional to the load *P* acting on plate *B* and is measured by the micrometer screw *G*, the end of which is immersed in the mercury.

The level of the mercury in the capillary can be adjusted to any desired height by turning the screw. The most practical manner of reading the load is to bring the meniscus to the fixed mark *H*, where it stood at "no load." The amount by which the screw is turned back is then the measure of the load applied. The dimensions of the apparatus are usually chosen in such manner that one complete revolution corresponds to 1,000 kg. pressure, and one division on the head to 10 kilos. When it is desired to apply a definite load, say 3,000 kilos, the micrometer is turned back three complete revolutions and then the load is gradually increased until the level of the mercury returns to its original height.

Readings are independent of the bore of the capillary *F*, so that an accidental breakage can be immediately replaced by another tube without influencing the accuracy of the apparatus. This dynamometer is very sensitive and at the same time of very rugged construction; it can be overloaded only when the testing machine itself is being wrecked. Each dynamometer is carefully calibrated by dead load up to its full capacity; the calibration can be checked at any time by hanging the entire machine up by the compression plate *B*. The load then shown on the dynamometer should agree with the weight of the machine, and if other comparisons be thought desirable extra weights may be added to the machine base.

The practical application of this dynamometer is shown in Fig. 1, a hardness-testing machine with two speeds; the high speed is applied to bring the ball quickly into its required position, the slow speed is used to apply the load. It is apparent that the main side screws can be made of any desired length and set at any reasonable distance center to center, so that very large pieces—like great gear wheels—can be tested at various points on the rim or teeth.

An especially interesting application is shown in Fig. 2, of a machine developed for the French Government. The entire frame can be rotated about an axis placed below the lower base frame of the machine. A counterpoise balances the weight of the frame and of the moving head, so that any required adjustments require very little power. The ball itself follows the curvature of the pointed part of the shell, so that it is always in the proper position for testing. The radius of arc of the circle described by the ball can be adjusted from 6 in. to 40 in.; it is set at the radius of the part to be tested, and the later held in place by an appropriate fixture or steady rest.

Coke as a Blast-Furnace Fuel

Operators believe that loss by "solution" of coke in the blast-furnace stack gases is detrimental to economical operation. A laboratory test has been devised at the Southern station of the Bureau of Mines by which the relative reactivity of cokes with carbon dioxide may be quantitatively determined. Correlation of test results with those of actual furnace practice will be undertaken on furnaces operating on coke from Alabama, Pennsylvania and Illinois coal.

Combustion of coke in the blast-furnace hearth has also been studied in the Birmingham district. Additional work will be done at furnaces in the Pittsburgh districts and at the furnaces of the St. Louis Coke & Chemical Co. at Granite City, Ill., which are operating on coke from Illinois coal. By means of analyses of gas taken from different parts of the blast-furnace hearth, the rate of combustion of different kinds of coke will be determined under actual operating conditions. Results so obtained will be correlated with the physical and chemical properties of the coke as determined by laboratory tests.

In making calculations of the efficiency of operation of a blast furnace, the amount of carbon available for combustion at the tuyeres is taken as the so-called fixed carbon of the proximate analysis. The official determination of volatile matter is made at a temperature of 950 deg. C. Since coke is subjected to temperatures up to 1,800 deg. C. before being burned at the blast-furnace tuyeres, there is the possibility that less carbon is actually "fixed" in a condition to reach the tuyeres than is indicated by the ordinary proximate analysis. Experiments are now under way at the Birmingham station of the Bureau of Mines in which the volatile matter of several varieties of metallurgical coke will be determined at temperatures up to 1,700 deg. C.

Recent Chemical & Metallurgical Patents

Coal Carbonization—In two patents Charles C. Bussey describes the apparatus and procedure for treating carbonaceous materials and recovery of the volatile hydrocarbon products of destructive distillation. The process is essentially an internally fired vertical retort or combination of producer and vertical retort. The process and apparatus are like those which were tested out several years ago in Brooklyn and later used to a limited extent in or near Louisville, Ky. One of the important features, more or less novel in this apparatus, is the reciprocating grate at the bottom which by alternate forward and backward movement at controllable intervals provides for the ejection of the carbonized residue at the bottom of the retort. (1,432,275-6. Charles C. Bussey, assignor to Samuel E. Darby, trustee. Oct. 17, 1922.)

Evaporating Milk—Various objections to the ordinary vacuum pan method of evaporation of milk are claimed to have been overcome by a process patented by David D. Peebles of Eureka, Calif., and assigned to Bair, Peebles & Tooby of Eureka. Among these objections may be mentioned the high initial expense of installation of a vacuum pan system; the tendency of the liquor foaming and priming, and being carried over with the vapor escaping from the pan; adhesion of the concentrated material to the heated surfaces of the pan, thereby resulting in scorching; the need of special apparatus for homogenizing the milk; the necessity of maintaining a high temperature in the vacuum pan to prevent incubation of the bacteria, thereby breaking down the chemical constituents of the original milk; and finally the necessity of separate sterilizing apparatus at destructively high temperatures. The present invention consists in the continuous and successive circulation of the milk through a heater under pressure and an expansion chamber closed against access of surrounding air, the temperature of the milk being suddenly raised in the heater above the temperature at which the germination of the active organisms takes place and suddenly reduced in the expansion chamber to a temperature below that at which such germination is active, and removing the vapors resulting from the expansion of the water of the milk in a separate expansion chamber. At each successive cycle in the process a percentage of dehydration is effected and the milk is condensed and made more sterile without altering its chemical composition. The milk is heated to approximately 160 deg. F., which is a pasturizing temperature, and then cooled to the temperature of the vacuum under which the concentrator is operating. A tubular heater is employed, the milk being circulated through the tubes. (1,438,502. Dec. 12, 1922.)

American Patents
Issued Jan. 23, 1923

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,442,814—Device for Spraying Paint. F. R. Long, assigned to American Car & Foundry Co., New York.

1,442,818—Derivatives of 1 4 Naphthylenediamine. G. T. Morgan; assigned to Imperial Trust for the Encouragement of Scientific and Industrial Research.

1,443,077—Process for Producing Sulphides. A. Helbronner and P. Piperdant, Nantes, France.

1,443,094—Method of Making Phthalic Anhydride. H. Sasa, Tokyo, Japan.

1,443,149—Rubber Composition. P. Schidrowitz, London.

1,443,161—Coke Oven. G. A. Bolz, Rahway, N. J.

1,443,184—Centrifugal Separator. R. E. Lapham, Oakland, Calif.

1,443,189—Plates for Vulcanizing Press. A. C. V. Malm, assigned to E. W. Bliss Co., Brooklyn, N. Y.

1,443,220—Recovery of Nitrogen Oxides. P. A. Guye and A. Schmidt, assigned to "L'Azote Francaise" Co. of Paris.

1,443,221—Insulating Material. J. Hawkridge, D. Robertson, C. J. Nevine, of London.

1,443,231—Non-Freezing Attachment for Water Tank. F. W. McCauley, Goodes, Va.

1,443,328—Explosive. E. Herz, Vienna, Austria.

1,443,330—Determination of Naphthalene in Gas. W. H. Fulweiler, assigned to U. G. I. Co.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Anthraquinone Dyes—Ewald Steinbuch, Franz Ackerman and Max Utzinger, of Basel, Switzerland, assignors to the Society of Chemical Industry in Basel, Switzerland, have patented a process for the manufacture of new condensation products of the anthraquinone series which contain in their molecule 1.3.5-triazine nuclei and constitute colored powders generally difficultly soluble in organic solvents and forming colored solutions with concentrated sulphuric acid. The condensation can be affected in such a manner that the respective anthraquinone and 1.3.5-triazine derivatives are left to react on each other for a sufficient length of time dissolved or suspended in suitable agents such as nitro-benzene, chlorbenzene, naphthalene, toluene, glacial acetic acid, etc., the temperature begin maintained constant as desired. The solvent may also be omitted by simply melting together the respective compounds to which a catalytic agent, such as cuprous chloride, may be added if necessary. (1,437,783. Dec. 5, 1922.)

Chrome Dyes—Fritz Straub, of Basel, Switzerland, has patented a method of making chromium compounds of azo dyes by treating an alkaline solution of the dye with a complex chromium compound formed by the action of alkaline suspension of chromium hydroxide on organic compounds containing more than one hydroxyl group, as polyvalent alcohols and phenols, tannins, saccharides and derivatives of cellulose.

In an example, 46.8 parts of caustic potash are introduced gradually into 100 parts of aqueous paste of hydrate of chromium oide, with stirring, care being taken that the temperature does not rise above 70 deg. C. After all the potassium hydroxide is dissolved, 20.8 parts of glycerine are added with stirring. The mass is heated to boiling and maintained in ebullition until all of the chromium hydrate is dissolved. To this solution is added 71.2 parts of the dye derived from 1-diazo-2-oxy-naphthalene-4-sulphuric acid and alphanaphthol. The dye dissolves quickly and the dark blue coloration of the resulting solution turns rapidly to blue-violet. The mass is boiled for 10 hours in a vessel provided with a reflux condenser, the temperature of the reaction being 100 to 102 deg. C. The mass is then diluted with 600 parts of cold water and the liberated caustic potash is neutralized with mineral acid and the dye salted out, filtered and dried. (1,440,566. Jan. 2, 1923.)

Cellulose-Ether Solvent — A compound solvent for alkyl ethers of cellulose, comprising a mixture of methyl alcohol and toluene, is covered by a patent taken out by Stewart J. Carroll, of Rochester, N. Y., and assigned to the Eastman Kodak Co. The solvent is designed to be used for film dope, where a very viscous solution is desired. The proportions recommended vary between 25 to 50 of methanol and from 50 to 75 parts of toluene. (1,441,143. Jan. 2, 1923.)

High Explosives for Detonators—Fulminate of mercury has long been the chief initiating explosive of commercial importance used in detonators. Its great advantage over other initiating explosives is that by its use detonation is assured, either by the spit of a fuse or other means of ignition or by moderate percussion. On the other hand, it exhibits several undesirable properties

in that it is easily affected by moisture, its detonating value is diminished by compression, it has a relatively low brisance, which renders necessary the use of an inner capsule or reinforced shell when it is desired to use fulminate of mercury as a priming charge in the TNT type of detonator, and finally because it has a corrosive action on a number of metals and alloys, thereby rendering them unsuitable for detonator casings.

The heavy metal azides, which are salts of hydrazoic acid, have been proposed as a substitute for fulminate of mercury, but they also have their drawbacks in that they are not easily ignited. It would seem that the desirable properties of the two types of explosives might be obtained by a proper mixture of the two, but unfortunately the azides corrode some of the metals and alloys which are not affected by fulminate of mercury, so that there is really no metal which could be used for a casing for the combination explosive.

Bennett Grotta, of the Atlas Powder Co. experimental laboratory at Tamaqua, Pa., has been granted a patent covering the use of the mercurous salt of hydrazoic acid in combination with fulminate of mercury for use in detonators. The mercurous salt is not nearly as unstable as the mercuric salt, and seems to be admirably suited for admixture with mercury fulminate because both compounds, being salts of the same metal, may be mixed without danger of chemical action, and in the second place, because there is no appreciable action between such a mixture and shells which would be suitable for fulminate detonators. It is claimed that the mercurous compound, in contradistinction to lead azide, does not form supersensitive copper azide. The inventor attributes this to either of two explanations: First, to the comparative positions of the metals involved in the electromotive series, and second, to the comparative solubilities of mercurous azide and lead azide in water.

Another advantage of the mercurous azide over the better known lead compound is that it is not attacked by the carbon dioxide of the air with consequent liberation of hydrazoic acid which in turn may act upon the copper of the shell with the formation of the super sensitive copper azide.

It is claimed that from the standpoint of detonating efficiency, the admixture of small quantities of mercurous azide with fulminate of mercury produces most gratifying results. It is said that the advantageous effects of such mixtures hold equally true when the mixtures include suitable proportions of potassium chlorate. (1,439,099. Dec. 19, 1922.)

Purification of Naphthalene—In using this invention, crude naphthalene is distilled and the vapor passed through sulphuric acid of about 66 deg. Bé. at a temperature high enough to avoid condensation of the vapor. The temperature is usually 134 to 144 deg. C. at the preferable pressure, but the operation may be at various pressures with corresponding change of temperature. The impurity in the vapor is sulphonated and forms a byproduct in the acid residue which is described as "useful in the arts as ingredients of synthetic tanning liquor, for saponification of oils, or for other well-known uses to which crude sulphonic acids may be put." (1,438,710. S. P. Miller, assignor to The Barrett Co. Dec. 12, 1922.)

French Patents

Separating Constituents of a Gas Mixture—To the gas or gaseous mixture are added particles of a solid substance, held in suspension therein and of such a chemical nature as to combine with the particular constituent to be removed, with formation of a fume or a fog. This fog is then precipitated by a high-tension electrostatic field. (Fr. Pat. 534,879. A. L. Stinville.)

Purification of Liquids Contaminated by Phenol—Liquors contaminated by phenol may be evacuated into rivers following their filtration through a bed containing certain aerobic bacteria which destroy the phenol, presumably by oxidizing it to innocuous substances. A filtering bed of humus (to protect the bacteria) mixed with coke is prepared which allows access of air circulated through it either by suction or pressure. Through this filter-bed activated sludge (drawn from the aeration chambers of sewage treatment plants) is allowed to percolate, after which it is topped with a layer of farm manure. The waste liquor to be treated is then passed through the filter bed. This liquor is generally a residual ammoniacal liquor from a gasworks or a coke-oven plant, which has been diluted by water or, better still, by the effluent itself, until it has no longer a highly toxic effect upon the filter-bed bacteria—viz., until the phenol content has dropped to below 3 parts in 10,000. For instance, in the operation of the filter, 10 to 15 per cent of the effluent is evacuated into the river and 85 to 90 per cent is recirculated through the filter to which is added 10 to 15 per cent of crude residual liquor (sometimes 5 to 30 per cent). One cubic meter of the filter-bed composition is sufficient for treating 60 to 120 liters of residual liquor each 24 hours. Since the filter is operated continuously, the reproduction and the growth of the phenol-destroying microorganisms compensate the losses. If the losses become excessive, the degree of dilution may be increased or the flow reduced. The amount of inflowing liquor may even be stopped altogether, thereby affording time for the replacement of the killed bacteria. The optimum filtration temperature is 20 to 25 deg. C. In the residual ammoniacal liquors the sulphocyanates are likewise oxidized by the bacteria, although subsequently to the phenols. For this type of waste liquor it is advisable to effect, prior to purification by filtration, the removal of the solid and tarry constituents, as well as the sulphides (CaS), by preliminary decantation followed by a filtration through an iron-oxide mass or blast-furnace slag. This may be supplemented by a special treatment for the elimination of the cyanogen compounds. (Fr. Pat. 533,922. The Koppers Co., Pittsburgh, Pa.)

Continuous Distillation of Bituminous Shales—This process consists in admitting air, occasionally even steam, into the lower part of a downwardly moving column of highly heated bituminous shale, whereby the residual carbon (10-12 per cent in the case of Autun shales) is converted into gas, the latent heat of which brings about the distillation of the upper layers of the shale column, and the condensable oils and the ammonia are swept out of the retort. In this manner an extraneous source of heat for carbonization is dispensed with. (Fr. Pat. 534,659. Société d'Etudes et de Recherches Minières du Centre.)

Separating Asphalt and Ozokerite From Hydrocarbons—Crude petroleum oils to be purified are subjected to a chemical treatment prior to distillation. The reagents proposed by the inventor are comparatively dilute sulphuric acid solutions (40 to 60 per cent H_2SO_4), to which small amounts of solutions of metallic salts have been added, particularly halogen derivatives of trivalent iron, the function of which consists in promoting the precipitation of the colloidal compounds present in the crude oils. The oils, after having undergone this treatment and having been subjected to a cooling process, abandon their solid hydrocarbons in the form of ozokerite and ceresin wax, and no longer in the form of a low-melting point paraffine. (Fr. Pat. 536,172. H. Neumann.)

Production of Metallic Powders—This process is applicable for instance to the pulverization of aluminum, magnesium, copper, zinc, etc., which metals are susceptible of undergoing superficial oxidation and also of combining with nitrogen. The metal is heated in the open air or in a closed crucible to a little above its melting point. The molten metal is then drawn off and subjected to the action of a jet of compressed nitrogen at a suitable temperature whereby it is solidified in the form of fine ellipsoidal globules. The nitrogen may be that extracted from the air, for instance in the form of waste combustion gases whose CO_2 has been removed by bubbling them through milk of lime. In the case of aluminum, for instance, the nitrogen forms at the surface of the globules a protecting layer of nitride which prevents access of atmospheric oxygen to the subjacent metallic aluminum. (Fr. Pat. 532,470. J. Sejournet.)

Esters From Aluminum Alcoholate—Aluminum alcoholates may be obtained by the action of alcohols on aluminum amalgam or preferably on a ternary aluminum alloy, the latter being more readily prepared. By causing such an

alcoholate to act on an ester there is displacement of the alcoholic radicle of the ester by that of the alcoholate, provided these have a higher molecular weight. The yield is excellent. The acetic acid esters derived from secondary amyl alcohol, phenylethyl alcohol, and linalool have thus been obtained from ethyl acetate, and the phenyl acetic esters of amyl alcohol and phenyl ethyl alcohol from phenylacetic acid. The process is particularly applicable in the case of the esterification of tertiary alcohols which do not resist well the action of mineral acids, anhydrides or acid chlorides. It is also well adapted in those cases where the preparation of the ethyl esters is less onerous than that of the corresponding anhydrides or acid chlorides. (Fr. Pat. 531,960, Société Laboratoire-Usine.)

Aromatic Nitro-Amino Compounds—The replacement of chlorine atoms of aromatic chloro-nitro compounds by amino-groups does not require that the reaction be carried out under pressure (in an autoclave) proving that ammonium acetate is used in a current of gaseous ammonia. The amino-derivative is separated by washing the reaction product with water. The ammonium acetate is used in a current of this manner have been prepared 2:4-dinitro-aniline, 1:3:4:6-diaminodinitrobenzene, 1:4:3:5-chloraminodinitrobenzene, 1:2:4.3:5-chlorodiaminodinitrobenzene, 1:2:4:5-dichloraminonitrobenzene, 1:2:4-aminochloronitrobenzene, 1:4.2-aminochloronitrobenzene, o-nitroaniline. (Fr. Pat. 432,405. Société Chimique de la Grande Paroisse, Lille, France.)

Improved Hydrogenation of Naphthaline—A nickel catalyst suitable for the hydrogenation of naphthalene and much more active than that obtained by reduction of its oxide is obtained by forming it in a colloidal condition in the hydrocarbon itself. A current of hydrogen is passed into 1,000 parts of naphthalene and 5 parts of nickel carbona. heated to 220 to 250 deg. C. under a suitable pressure. The precipitated nickel carbonate is already in a finely divided condition. The dispersion is pushed even further by the liberation of carbon dioxide and the reduction process. (Fr. Pat. 533,033. Prax Chemische Versuchs und Verwertungs Gesellschaft m.b.H.)

De-inking Paper—The ordinary beater engine is equipped with a screen which holds back the pulp while the washing water is afforded free passage through it and through a circulating mechanism. In this engine a charge is made up composed of 1 ton (metric) of waste paper, 100 kg. of sodium carbonate, 320 hl. of water and 150 kg. of bentonite or analogous product. Bentonite is a clay having an exceedingly fine grain. The material used in this process should be such that at least one-half of its particles have a diameter less than 0.0015 mm. and 70 per cent of which is in a colloidal condition. The ink attaches itself to the colloid and is carried with it through the screen. After this operation an acid or an acid salt is used to neutralize the excess alkali and to brighten up the color of the paper. (Fr. Pat. 535,859. H. R. Eyrich and J. A. Schreiber.)

Production of Alumina and Aluminum Compounds—Bauxite is treated with nitric acid, and the iron is precipitated from the resulting solution. The purified solution gives pure aluminum nitrate, which, when calcined, yields alumina and nitrous vapors which are reconverted into nitric acid. The alumina may be extracted from the solution by any other method—for instance, by precipitation. (Fr. Pat. 529,569. Norsk Hydro-Elektrisk Kvaelestofaktieselskab, Christiania, Norway.)

Production of Aluminum and Potassium Compounds—Potash-bearing aluminous minerals, such as leucite or feldspar, are treated by mineral acids, preferably nitric acid. It is advantageous to carry out the operation in two phases, by first using an amount of acid sufficient to dissolve only the potash in the mineral and treating the residue from this solution with the amount of nitric acid, required for the dissolution of the aluminous compounds. (Fr. Pat. 529,570. Norsk Hydro-Elektrisk Kvaelestofaktieselskab, Christiania, Norway.)

A New Hypochlorite Bleach—A mixture of chlorine and air is passed over a paste consisting of lime and water to which has been added a saturated solution of calcium chloride and calcium hypochlorite. This paste may also contain the products of decomposition of calcium hypochlorite, as well as the soluble salts present in the caustic lime used. The reaction mass is continuously stirred during the chlorination. The resulting paste is filtered and the solid part which is the active product, is dried in a vacuum at a low temperature. The resulting product is characterized by its stability. (Fr. Pat. 530,706. P. Andren.)

Breaking Down Emulsions—A reagent is added to the emulsion which disperses as a colloid in the continuous phase of the emulsion and hence comes automatically into contact with the suspended globules, causing the latter to coalesce. The reagent used is a compound which acts as an emulsifying colloid tending to invert the form of the emulsion, and a second compound capable of dissolving the former and the continuous phase of the emulsion. Good results are obtained, for instance, by means of a reagent composed of about 25 per cent of a soda soap, 10 per cent of water and 65 per cent of oleic acid. This reagent may be prepared so as to render it colloidally soluble in oil. Likewise good results are obtained from a reagent composed of 4 per cent of calcium oleate dissolved in a mixture of 50 per cent alcohol and 50 per cent glycerine to which 1 per cent of gelatine is added as a stabilizer. A reagent answering this description is soluble in water, although it contains hydrophobe colloidal calcium oleate. One practical example of the invention consists in adding 1 per cent by weight of a reagent composed of 40 per cent of water, 35 per cent of free rosin and 25 per cent of soda-rosin soap to a viscous oil-water emulsion, the mixture being stirred to promote the dissolution of the reagent in the emulsion, and centrifuged whereby the water is caused to separate from the oil. (Fr. Pat. 532,148. Sharples Specialty Co., West Chester, Pa.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Antiseptic Soap—An antiseptic and insecticidal compound comprises soap, alkali benzoate and vegetable or mineral tar. In examples, 80 parts of hard or soft soap are mixed with 10 parts of sodium or potassium benzoate and 10 parts of birch tar; or a mixture of 80 parts of fatty acids, 10 parts of benzoic acid and 10 parts of birch tar is saponified in a manner not involving boiling or salting out of the soap. (Br. Pat. 186,078. R. Macpherson, Worthing, Sussex, and W. E. Heys, Bushey, Hertfordshire. Nov. 15, 1922.)

Synthetic Resins—Resinous products are obtained by heating phenols with sulphur in the presence of a base, the amount of base employed being not more than one-fifth equivalent of the phenol; from 2 to 3 atoms of sulphur per molecule of phenol are used and the heating continued until evolution of sulphuretted hydrogen ceases. Catalysts such as halogens or compounds yielding halogens may be added. The products are fusible and soluble in alkalis, alcohol, acetone or benzene, and may be converted into insoluble infusible products by prolonged heat, or heat and pressure, or they may be hardened by treatment with a small amount of formaldehyde or substances yielding it. According to examples, the following parent materials are employed: phenol, sulphur, and potassium hydrosulphide; o-cresol, sulphur and potassium carbonate; phenol, tri-cresol, sulphur, aniline and iodine; resorcin or α- or β-naphthol, sulphur and caustic soda; an example of hardening the resin by means of hexamethylene-tetramine is also given. (Br. Pat. 186,106. T. M. Hickman, Wolverhampton. Nov. 15, 1922.)

Chrome Alum—Chrome alum crystals are prepared by adding to green chrome alum solution small quantities of potassium bichromate, sulphuric acid and sulphurous acid, when the violet chrome alum is immediately produced and is readily crystallized. The quantity of potassium bichromate is not sufficient to oxidize any iron present and the sulphuric acid is equivalent to the potas-

sium of the bichromate. In an example. ferrochromium is dissolved in sulphuric acid, and about half of the ferrous sulphate is removed by crystallization. The ferrous sulphate is separated in a centrifugal machine and the necessary quantity of potassium sulphate is then added. The green solution is then treated as above described to obtain chrome alum crystals.

A second specification covers a modified process involving the intermediate production of chromium hydroxide. Ferrochromium is dissolved in sulphuric or hydrochloric acid, and an alkali hydrate or carbonate or an alkaline earth hydrate is added in quantity sufficient to precipitate the chromium a-hydroxide free from iron. The precipitate is washed and dissolved in sulphuric acid, and potassium sulphate is then added to produce chrome alum. (Br. Pat. 187,231 and 187,232; not yet accepted. Chemische Fabrik in Billwarder vorm. Hell and Sthamer Akt.-Ges. and P. Hasenclever, Hamburg. Dec. 13, 1922.)

Evaporation In evaporating liquids in multiple-effect apparatus particularly of the kind described in specification 180,963 in which the liquid is fed in parallel to the effects the liquid is passed in series through a number of multiple-effect plants, the temperature ranges of which coincide or overlap substantially. In concentrating brine or other liquid the boiling point of which rises on evaporation, the first effects of each plant are preferably supplied with steam from the same source and the last effects are connected to the same condenser, and the number of effects in each succeeding plant is progressively diminished. In evaporating cane or beet sugar solutions, the concentration obtained in the last plant may be such that crystals separate in the effects of this plant, or crystallization may be effected outside the plant in crystallizing vessels which may be supported on wheeled devices or in heated pans in which slow evaporation takes place. When the concentrated liquid is to be cooled to cause crystallization or for other purposes, the vessel containing the liquid is connected to the vapor spaces of effects at progressively lower pressures as to cause the liquid to flash off steam and to lower the temperature in stages. The method of cooling the concentrate and recovering the heat for use in the evaporating process may be used in plant in which the multiple-effect apparatus is replaced by apparatus of the kind described in specification 12462/11, in which the vapors evolved on evaporation are compressed and used as the heating agent. In concentrating impure liquids such as sea water, which at one stage of the concentration will deposit impurities, such as calcium sulphate, etc., on cooling, the cooling may be effected by flashing-off vapors from the solution by connection with effects of lower pressure, during the passage of the solution from one evaporating plant to the next. The solution may be preheated before passage into the next plant by heat-exchange with the solution from the first plant. According to one provisional specification the control device described in specification 180,963 for controlling the passage of vapor from one effect to another may be used also to control the flow of liquid from the source of supply into the effect. (Br. Pat. 187,260. T. Rigby, Westminster. Dec. 13, 1922.)

Fertilizers—Manures containing an ammonium compound or compounds and a secondary fertilizing agent or agents, such as a salt of potassium or a phosphate, are obtained by reaction between gases containing ammonia and the semi-dry product obtained by treating with acid a naturally occurring material that contains the secondary fertilizing agent or agents, but which is free, or almost free, from lime and is not generally regarded as a manure in itself. Thus clay containing a compound of potassium may be treated with sulphuric acid, if desired after drying and pulverizing, in sufficient amount to constitute a semi-dry mass, which is brought into contact with gases containing ammonia.

The product contains the oxides of iron and aluminum, and ammonium sulphate, together with a soluble compound of potassium, the content of which may be increased by direct addition of potassium salts. Other examples of naturally occurring materials suitable for use in the process are alunite and shales containing iron, aluminum, sulphur and potash, with or without phosphorus. Alunite may be calcined and used without any addition of acid. Instead of sulphuric acid there may be used sulphur dioxide or trioxide, hydrochloric or phosphoric acid, spent pickling liquor, or acid salts, or mixtures of any of these. Where phosphoric acid is used, gases containing ammonia may be treated in a heated condition; if, however, the absorption is allowed to proceed for a long time at atmospheric temperature, material containing tri-ammonium phosphate is obtained. The products may be lixiviated to remove the soluble salts, or they may be heated to about 400 deg. C., when about 50 per cent of the ammonia present is evolved, leaving a residue still suitable for use as a fertilizer or for re-use in the process. (Br. Pat. 187,251. E. L. Pease, Hurworth Moor. Dec. 13, 1922.)

Motor Fuel—A fuel for internal-combustion engines comprises a mixture of ether, alcohol and a volatile vegetable oil such as rosin oil or oil of turpentine, with or without a small amount of caustic soda. The preferred proportions are 36.75 parts by volume of alcohol, 62 parts of ether, 1 part of rosin oil and 0.25 part of a saturated solution of caustic soda in alcohol. "Commercial" ether may be used in slightly larger proportion. The fuel is miscible with lubricating oil and thus is suitable for two-stroke engines. (Br. Pat. 187 326. H. R. Giles, London. Dec. 13, 1922.)

Motor Fuel—The method of producing an alcohol fuel described in specification 178,498 and consisting in agitating, under pressure, a mixture of commercial alcohol and acetone with calcium carbide, is applied to monohydric alcohols, other than commercial alcohol, such as amyl, butyl and propyl alcohols. The alcohols preferably contain up to 10 per cent of water, and 5 to 40 per cent or more of acetone is added. The pressure is preferably from 10 to 40 lb. per sq.in., depending on the amount of acetylene to be absorbed. The lime in solution or suspension in fuels of this type is removed by chemical means, such as by treating the fuel with ammonia and passing in carbon dioxide, or by the addition of powdered ammonium carbonate. A suitable lubricant may be added. (Br. Pat. 187,335. S. W. Blake, Oudtshoorn, South Africa. Dec. 13, 1922.)

Coal Carbonization A mixture of powdered caking and non-caking coal is carbonized at a temperature of between 600 and 760 deg. C., whereby expansion and the development of a highly cellular structure is avoided and a bright and hard coke is obtained. Coke breeze may be substituted for a portion of the non-caking coal, or the latter may be replaced by a caking coal the caking properties of which have been destroyed by a preliminary heat treatment of between 100 and 350 deg. C. (Br. Pat. 187,336. J. Roberts, Glamorgan. Dec. 13, 1922.)

Synthetic Resins — Synthetic resins are produced by subjecting an aldehyde or its products of condensation or polymerization to the continued action of a mineral acid or acid salt, in the presence of a solvent if desired and preferably at a raised temperature. The products may then be hardened by prolonged heating at a high temperature, with or without the separation of the excess of acid. Further hardening may be effected by fusion with metal oxide or esterification with an alcohol, such as glycerine, before or after the heat-treatment; subsequent oxidation bleaches the products and makes them soluble in borax. The synthetic resins, when dissolved in the usual resin solvents, can be used as lacquers, polishes and finishes; and, being of low melting point, they can be added to other resins to render them more fusible. According to the examples, (1) acetaldehyde and sulphuric acid are heated together at 40 deg. C. for some hours and then raised to 100 deg. C. until a sample sets on cooling to a tough mass; the product is maintained in the molten condition, about 150 deg. C., for a long time, and sets when cold to a hard resin; (2) crotonic aldehyde is heated with hydrochloric acid, or with sulphuric acid in the presence of acetic acid as a solvent, or acetaldehyde is heated with sodium bisulphate solution, and the products in each case are further treated as in example (1). (Br. Pat. 187 619; not yet accepted. Consortium für Elektrochemische Industrie Ges., Munich. Dec. 13, 1922.)

Muscle Shoals Disposal Discussed Anew

Hearings on Resolution to Create Revolving Fund for Government Fertilizer Business Renews Storm Over Nitrate Plant Sale

REVIVAL of the controversy over the disposition of the government's hydro-electric development and nitrate plants at Muscle Shoals has come in Congress as the result of hearings by the House Committee on Agriculture on the resolution to create a revolving fund of $10,000,000 for the purchase by the federal government of stocks of nitrate of soda and sale at cost to farmers. This resolution has passed the Senate.

While the resolution has no direct connection with the Muscle Shoals proposition, the latter were brought into the discussion because of the fertilizer portion of the Ford offer.

Advocates of acceptance of the Ford offer for the properties have come into conflict with those who contend that this bid is not acceptable, and with others who are urging a government corporation to operate both the power project and the chemical works.

The sharpest conflict over the Muscle Shoals project was not before the House committee, but was inspired by its hearings. Bernard Baruch, former chairman of the War Industries Board, appeared before the committee among other witnesses, advocating adoption of the resolution by the House. Subsequently Mr. Baruch sent a letter to Gray Silver, representing the American Farm Bureau Federation, in which he recommended acceptance of the Ford offer for Muscle Shoals because of the clause which would specify production of fixed nitrogen. This letter was made public and caused a heated reply from Senator Norris, author of a bill to establish a government corporation, in which he charged that Mr. Silver represented Mr. Ford rather than the farmers of the country. Mr. Silver subsequently called upon the Nebraska Senator for a retraction and asked an investigation by the directors of the Farm Bureau.

Baruch Supports Ford

The conclusions given in Mr. Baruch's letter are based on a survey of Leland L. Summers, an engineer employed by Mr. Baruch.

Mr. Summers considered every possible method of disposing of the plant, weighing the merits of each. Mr. Baruch limited his suggestions to the following three:

1. Government development. Except as a last resort, I am opposed to this on account of its inherent disadvantages.

2. Combination of industry either with government co-operation or independently.

3. The Ford development. This apparently is the only offer that has come forward so far from a private source promising development along commercial lines. If no more advantageous offer should be made, the arguments against awarding the contract to Henry Ford would not be convincing.

Urges Modification

"Without commenting upon the terms of the contract or considering the adequacy of the price, there are certain modifications or clarifications that should be made," says Mr. Baruch. "All doubt in regard to Mr. Ford's personal liability should be removed.

"The most important thing that ought to be clarified is the following: That Mr. Ford undertakes to make 40,000 tons of fixed nitrogen per year, and if he does not make it the property is to revert to the government. After all, it is the fixing of the nitrogen that is the crux of the whole contract. I am quite sure that the contract means to cover this point, but it should be made clear.

"However great the pecuniary rewards might be to Mr. Ford, or to anyone else who will undertake it, there will be added a contribution of almost inestimable value to the future of American agriculture and the safety of America in time of war."

Work on Dam Progresses

The concrete work in the foundation in the cofferdam across the north channel at Muscle Shoals has been finished and the cofferdam is being torn out. Brigadier-General Harry Taylor has returned from a visit to the work and reports that the higher water in the Tennessee River in no way has delayed the work thus far. During December, due largely to the favorable season, 41,491 yd. of concrete was put in, he said. The latest figures available when he left Muscle Shoals were those from Jan. 1 to 20, during which period 24,279 yd. of concrete was put in.

General Taylor states that the work is being carried well within the estimates and that it can go forward at the maximum rate if the Senate approves the appropriations allowed by the House. The House voted $6,998,800 in cash and authorized $10,501,200 for continuing contracts. This amount will complete the dam and the power house and will permit of the installation of eight power units. Practically all of the waterwheel machinery for four of these units now is on the ground and con be installed immediately when they are ready for it.

New Appropriation Proposed

So that the possibilities of Nitrate Plant No. 1, at Muscle Shoals, in the matter of fertilizer production may be known, Senator Norris, chairman of the Committee on Agriculture, has proposed the following legislation:

"For the improvement of Nitrate Plant No. 1, at Muscle Shoals, Ala., by the installation of new machinery therein, in order that said plant may be utilized for experimental purposes in extracting nitrogen from the air with a view of lessening the cost of explosives in time of war and fertilizers in times of peace, $2,000,000."

Nitrate May Be Sold to Farmers at Cost

The resolution authorizing the President to purchase nitrate for sale to farmers at cost and creating a $10,000,000 revolving fund for this purpose has been ordered reported favorably by the House Committee on Agriculture. It has been adopted by the Senate. This is one of the measures advocated by the farm bloc in Congress.

By the terms of the resolution, the President is "authorized and directed to procure, or aid in procuring, such stocks of nitrate of soda as he may determine to be necessary and find available for increasing agricultural production during the calendar year 1923, and to dispose of the same at cost, payable in advance." The President is authorized to make such regulations and to use such means and agencies of the government as he may deem best in carrying out the provisions of the resolution.

Canada May Be Arsenic Source

In the calculation of supplies of arsenic which might be secured from abroad, the possibilities of an expanded production in Canada seem to have been overlooked. Advices reaching Washington are to the effect that Canadian exports can be materially increased. Steps are now being taken by government statisticians to ascertain the approximate possible increase of the Canadian output.

Officials Still Grope for Dye Valuation Basis

Importers and Manufacturers Unable to Agree on Definition of Term "Competitive"—May Use Trade Journal Prices as Authority

Suggestions for regulations regarding the administration of the coal-tar product paragraphs of the 1922 tariff bill have been submitted to the Customs Division of the Treasury Department by the New York appraiser's office, which has been conducting research work on the subject. They have been taken under advisement, with indications that formal regulations will be promulgated before the end of February.

One of the stumbling blocks that has been encountered in framing these regulations is the proper definition of "competitive." The tariff act provides that imported coal-tar intermediate and finished products which are comparable, and thus competitive with domestic products shall be assessed on American valuation, a considerably higher rate than the United States selling price, which is to be the basis of assessment of non-competitive products. The definition has not been decided by the Treasury Department.

When Is Product Competitive"?

It has been determined, broadly, that a coal-tar product of domestic manufacture shall not be considered competitive with a comparable imported product unless "freely offered for sale in the usual course of business." Thus, if a certain color, for instance, is produced in the United States in such limited quantities as to be wholly insufficient to supply the demand, it will not be able to command the protection of the higher customs duty against an imported competitor because not "freely offered for sale." It is considered also that certain price factors will be taken into consideration under this part of the proposed regulations in determining the question of competition.

It has been no secret that the work of determining such valuation has been shunned by the Board of Appraisers and customs officials because of the great difficulties in arriving at an equitable basis for determining the American valuation of these products. The several conferences which have been held failed to clarify the situation to any extent. In fact matters have virtually reached an impasse.

Daily Source of Trouble

Instances of the chaotic situation which has been reached are an almost daily occurrence in the fine chemical trade. An importer desires information on a coming shipment of acetanilide. He calls the proper official and asks the duty on it. He is told 7c. per pound specific and 55 per cent ad valorem on the basis of American valuation. So far, so good. He then asks for purposes of computing the actual duty in dollars and cents what the American valuation is. He can get no answer, for there is none. The effect upon trade is apparent.

May Use Journal Prices

A proposal has recently been made to the effect that for purposes of American valuation of these items the average prices are reported in the three leading chemical and drug trade journals be accepted as the American value of the item in question. The trade has welcomed this suggestion as a way out of a very troublesome and confusing situation. It is proposed that the appraisers accept the average prices of drugs and chemicals, as quoted by the recognized authorities among the trade publications, and assess the duties upon this average. This would simplify and clarify the work of the appraisers as well as the actual business of importing such materials as come under the American valuation plan in the tariff law. Representative interests in the trade who have been interviewed refused to make any comment on the scheme in the absence of any definite information regarding the attitude of officials at Washington.

Daily Customs Reports on Dyes

So that current information may be available as to the volume of dye imports, the Department of Commerce has stationed a man in the New York Custom House to make a special study of these imports and furnish information from day to day as to the character of the receipts of foreign dyes.

Government Will Sell Nitrate in Small Lots for Farmers

Formal reannouncement has been made of the sale of 28,000 short tons of surplus nitrate of soda held by the government at the Old Hickory Ordnance Depot at Jacksonville, Tenn. This material is being offered for sale in lots of 20 short tons or more. Bids will be received at the Army Building 39 Whitehall St., New York, until noon, Feb. 15.

This surplus nitrate previously had been offered for sale in lots of 100 tons or more. The offer was withdrawn, however, after several Senators and Representatives had petitioned the Secretary of War to lower the minimum limit so that farmers could purchase the material for fertilizer purposes.

Leather Chemists to Meet at White Sulphur Springs

The American Leather Chemists Association will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W. Va., on June 7, 8 and 9. Full information concerning details of the meetings, hotel rates and transportation may be obtained by addressing H. C. Reed, secretary, 22 East 16th St., New York City.

Alien Property Bill Revised

Winslow Bill Now Provides Return of Confiscated Alien Property Valued at Less Than $10,000

Revision of the Winslow bill to return certain classes of trusts held by the Alien Property Custodian has been directed by the House Committee on Interstate and Foreign Commerce, this duty being referred to a subcommittee composed of Representatives Graham of Illinois, Newton of Minnesota and Johnson of Mississippi.

Change in sentiment came among members of the committee when the State Department, aroused by reports that the majority of the committee inclined to go further than recommended by Colonel Thomas W. Miller, Alien Property Custodian, who urged return of all trusts valued at $10,000 or less, and $10,000 of the value of larger trusts, and voiced disapproval of lowering the holdings to a point which might not secure payment of American citizens' claims against Germany. Some members of the committee previously had favored return of 50 per cent of the value of all trusts over $10,000.

Will Return Smaller Trusts

By vote of the committee, the subcommittee was instructed to redraft a bill providing for return only of those trusts valued at $10,000 or less which are not involved in litigation. The question of what shall be done about patents was reserved for a later vote. Indications are that patents and trademarks will be excepted from the terms of the bill. If this were done, questions affecting the Chemical Foundation and certain patents used by the War Department and Navy Department would be deferred.

There are 28,144 trusts now held by the Alien Property Custodian valued at $10,000 or less, and to return these would involve $22,122,002, which would leave a balance on 2,224 larger trusts of $296,236,899, according to testimony of Colonel Miller.

Forest Products Chemicals Exhibit to Feature Paper Show

In connection with the Paper Industries Exposition, which is to be held in the Grand Central Palace, New York, during the week of April 9, the management has decided to install a booth devoted to dendrochemistry, wherein will be exhibited all of the forest products chemicals which may be produced in the working of the forest for the paper industry. This exhibit is to be purely educational in character and it is hoped to get representative exhibits which will demonstrate to visitors the possibility of profit from the utilization of the chemical byproducts of the forest.

A general request for material for this exhibit has been broadcast. The display will be purely educational, so that no advertising of individual companies or persons will be permissible, except the acknowledgment card giving the names of those who furnish exhibits.

Gas Explosion Wrecks Springfield Plant

Purification Building of Gas Light Company Explodes, Killing Three and Causing Heavy Property Loss

An explosion of the gas-purifying plant of the Springfield Gas Light Co., Springfield, Mass., resulted in three deaths, scores of injuries and property loss running into several hundred thousands of dollars. For the most part, the brunt of the blow fell on business buildings, but in one section of the river front district, in which the explosion occurred, a residential district of tenements and flats, houses were made uninhabitable. Shattered windows, roofs, and in some cases walls that collapsed with the concussion, caused half a hundred families to vacate their homes.

Cause Unknown

Explanation of the explosion was lacking. Officially, the Gas Light Co. said the cause was undetermined. Arthur S. Hall, works manager and superintendent, said he could account for it only on the theory that a slow leak of gas had caused an accumulation under the roof, and that this gas pocket became ignited in some way. He asserted that the machinery, which constituted most of the plant, was virtually intact, and that the damage practically was limited to roof and walls.

The purifying building is about 120 ft long, half as wide and divided into two sections. That to the east was three ordinary stories high, that to the west about half a story lower. The explosion occurred in the eastern section. The western section suffered little more than did some buildings half a mile away, and to the north the main gas-making plant lost only its windows, which were shaken out by the blast.

The section that was the scene of the explosion was wrecked, but not entirely. The walls went out and the roof went up, but the machinery that they housed can be replaced and repaired.

Gas and Fuel Section of A.C.S. Plans Motor Fuel Symposium

In accordance with a resolution passed at the Pittsburgh meeting of the American Chemical Society the officers of the Gas and Fuel Section are arranging a second sectional meeting for the New Haven meeting. The section program will consist of papers on gas and fuel chemistry and a symposium on motor fuels, held jointly with the Petroleum Division. Under the rules of the society, papers presented at the meeting must be presented by members and must be listed in the final program. In order that they may be so listed the title and an abstract of the paper, preferably about 100 words, must be in the hands of the secretary of the section not later than March 8. The titles and abstracts of articles should be sent to R. S. McBride, 617 Colorado Building, Washington, D. C.

Cresol May Be Placed on Free List

Classification experts of the Treasury Department have prepared a ruling, which probably will be promulgated as a Treasury decision, that cresol shall be admitted without payment of duty under the tariff act. If this ruling is confirmed, other tar distillates with distillation characteristics similar to those of cresol will also be entitled to entry under the free list.

Paragraph 27 provides that all tar distillates yielding 5 per cent or more tar acids below 190 deg. C. or yielding 75 per cent or more tar acids in the portion distilling below 215 deg. C. shall be dutiable. Paragraph 1549 provides for duty-free importation of tar distillates which yield in the portion distilling below 190 deg. C. less than 5 per cent tar acids, but makes no reference to distillation at 215 deg. C. Cresol does not yield 5 per cent tar acids below 190 deg. C. but does give more than 75 per cent below 215 deg. C. It thus falls under both paragraphs but since paragraph 27 permits alternate tests, while paragraph 1549 provides a single requirement which is met by cresol, it has been held that cresol should be entitled to classification under the latter paragraph.

Canadian Paper Mills Plan Expansion

Plans have been perfected or are rapidly maturing for considerable expansion among the paper mills in the vicinity of St. John, N. B., involving a total investment of many millions of dollars.

The construction of a large addition to the plant of the St. George Pulp Co., Ltd., St. George, to provide extensive increase in capacity is planned and will probably cost more than $200,000.

The Nashwaak Pulp & Paper Co., Ltd., will proceed with the construction of an addition to its St. John pulp mill, designed to increase the capacity of sulphate pulp approximately 50 per cent during the present year.

The Bathurst Co., Ltd., has construction under way and will push to completion a new mill at Bathurst, to have a maximum capacity of 20,000 tons of newsprint and 30,000 tons of sulphate pulp per annum.

The International Paper Co., New York, is projecting a large mill in the Grand Falls district, in connection with an important hydro-electric development.

The Snowball Co., Ltd., is arranging to operate its mill at Chatham at full capacity, and a number of improvements and extensions will be made.

The Fraser Companies, Ltd., is planning for the construction of a large new paper mill on the St. John River, vicinity of Grand Falls, to include a complete sulphate pulp mill; the last noted company also has tentative plans under consideration for enlargements in its present paper mill at Edmunston.

Gathmann Solvent Recovery Process Suit Settled

Holder of Patent Rights Loses Suit Against Navy Department

There was no contract between the Navy Department and Louis Gathmann whereby the government was bound to use his process for drying smokeless powder and recovery of the solvent, according to a decision of the United States Supreme Court affirming the action of the Court of Claims in dismissing a claim of $236,750 filed against the government by Olga Gathmann Foley, administratrix.

Furthermore, according to the Supreme Court decision, there was no distinctive feature of the Gathmann process which entitled it to patent.

By letters exchanged between Gathmann and the Ordnance Bureau of the Navy Department, the latter, in 1904, agreed to install apparatus at Indian Head, Md., for experiment with Gathmann's process and to pay a royalty of 1 cent per pound on all powder thus dried if the method proved satisfactory. After several months Gathmann was notified that the experiment had not proved satisfactory. The administratrix of his estate filed a claim, asserting that the process had been used and that the letters established a contract. The Court of Claims and the Supreme Court held that the letters constituted an option, not a contract.

New Cellulose Division of A.C.S Seeks Support

The Cellulose Division of the American Chemical Society has recently been authorized as a permanent division of the society and wishes to enroll as members in the division all those who are interested in cellulose chemistry either from a scientific or practical standpoint. All members of the American Chemical Society wishing to become members of this division are requested to send their names, business connections and one dollar dues to the secretary, L. F. Hawley, Forest Products Laboratory, Madison, Wis.

Eyesight Conservation Council Appoints Directors

Election of Secretary James J. Davis of the U. S. Department of Labor and of Prof. F. C. Caldwell of the department of electrical engineering, Ohio State University, as directors of the Eyesight Conservation Council of America is announced by L. W. Wallace, president of the Council, the annual meeting of which was held in New York City, Feb. 6.

Secretary Davis and Professor Caldwell will act with leading engineers, educators, state and federal officials, economists and civic leaders in carrying on a nationwide plan to conserve vision in industry and education. The movement is being directed from New York by Guy A. Henry, general director of the Council.

December Chemical Exports Decline

Show Improvement Over Same Period Last Year, However

While there was a decrease of nearly half a million dollars in the value of chemicals and allied products exported during December as compared with the value of exports in November, export still ranged well above those of December, 1921. The decline in December of 1922 did not apply to the same extent to chemicals proper. In that case the value of the exports in December was only about $200,000 under those of November.

In December, 1922, there were substantial increases in acid exports, the increase being particularly notable in boric acid, where the amount exported increased from 82,506 lb. in November to 503,263 lb. in December. Exports of copper sulphate more than doubled in December, as compared with November, as did the value of exports of calcium carbide. Exports of formaldehyde fell off, as did those of cyanide of soda and water glass and caustic soda. There were substantial increases in exports of borax and of soda ash.

Exports of pigments, paints and varnishes continued at about the November rate, which is substantially above the rate of export during the corresponding period of 1921. The value of exports of fertilizers dropped about $300,000 as compared with November, but were in excess of the value of exports in December of 1921. Exports of sulphate of ammonia aggregated 10,716 tons, as compared with 9,220 tons in November. Exports of explosives increased decidedly. The figures of those of the Bureau of Foreign and Domestic Commerce.

Comparative figures showing the volume of exports of some of the chemicals of less importance are as follows:

	Dec., 1921 Lb	Dec., 1922 Lb
Carbolic acid	7,511	93,461
Magnesium sulphate		157,167
Chlorate of potash	78,399	48,431
Thorium nitrate		96
Zinc chloride		875
Carbon and lamp black		787,196
Litharge	74,619	193,184

Industrial Situation in the Ruhr Being Studied by Government

A study of the effect on world chemical markets by the occupation of German territory by the French is being made by government specialists. Unofficial reports are to the effect that most of the chemical plants still are in operation, but cable advices to the Department of Commerce on Feb. 1 indicated that the continuance of operations is highly uncertain. The entire industrial situation in the occupied region was described as critical.

A large number of chemical plants in unoccupied Germany are affected by the situation, since they depended on the Ruhr for coal tar and intermediates. While it is believed that foreign orders will be sent forward through France as long as stocks last or output can be maintained, the matter of transportation even by that route is uncertain.

The Commerce Department's cable also contained the information that Germany had discontinued deliveries of reparation dyes to France and to Belgium, but that deliveries to England and to the United States were continuing.

At the State Department no comment was forthcoming on the dye situation, but it is known that an active cable correspondence is being conducted and there is reason to believe that the negotiations in connection with the application of dye deliveries on the account of the United States against Germany for costs of the Rhine army are in a precarious state.

Personal

Prof. VICTOR ANDRES BELAUNDE, of the University of St. Marcos, Lima, Peru, is in New York City, and can be reached through the Peruvian Legation. He is editor of the *Mercurio Peruano*.

Dr. LEONARD H. CRETCHER has been appointed to the research staff of the Mellon Institute, Pittsburgh, Pa., to head an industrial fellowship devoted to the synthesis of chemicotherapeutic products. Dr. Cretcher is a graduate of the University of Michigan, studied one year in Germany and afterward took his Doctor's degree at Yale University. During the war he was commissioned a Captain in the Chemical Warfare Service. Later, at the close of the war, he became connected with the research department of the National Aniline & Chemical Co., subsequently being placed in charge of one of the large dye works of the company in the Buffalo, N. Y., district.

B. H. DELONG, metallurgist of the Carpenter Steel Co., Reading Pa., presented a paper on "The Manufacture of Alloy Steels" before the Washington Chapter of the American Society for Steel Treating at its monthly meeting on Jan. 26.

W. H. HENDRICKS, general sales engineer of the N. J. Zinc Co., New York, was the speaker at a meeting of the N. E. Paint and Varnish Production Club, Jan. 18. He discussed the history of lithopone from the inception of the industry to the present-day production. He also answered a number of questions concerning lithopone and zinc oxide.

THOMAS J. KEENAN, well known to the paper industry through his long years of work with the Technical Association of the Pulp and Paper Industry and as editor of *Paper*, has retired from that editorship. He will devote his time for the present to the coming Paper Industries Exposition which will be held in New York during the week of April 9.

W. F. LANTZ has been appointed chief chemist at the plant of the Bethlehem Steel Co., Bethlehem, Pa., to succeed A. D. SHANKLAND, who has been appointed metallurgical inspector at the No. 1 and No. 2 mills.

GEORGE D. PAINE, formerly of Chicago but more recently with Cook & Swan, N. Y., has been transferred to the latter company's office at 128 N. Wells St., Chicago, as manager.

DONALD K. PATTILLO has severed his connection as chemical engineer with the Hamersley Manufacturing Co., of Garfield, N. J., to accept a position as research chemical engineer with the Western Electric Co., of Chicago, Ill.

O. D. STREET, well known for the last 10 years as general manager of distribution of the Western Electric Co., has been elected a vice-president of the McGraw-Hill Co. He will have executive charge of *Electrical World*, *Electrical Merchandising*, *Journal of Electricity and Western Industry*, *Industrial Engineer*, *Electric Railway Journal* and *Bus Transportation*.

Obituary

GEORGE ELLIOT BROWN, vice-president, Swan & Finch Co., New York, refiners and dealers in oils, died suddenly on Jan. 24 from pneumonia, after a brief illness at his home in Norwalk, Conn. He was 55 years of age.

WILLIAM P. WAUGH, consulting engineer for the H. H. Robertson Co., Pittsburgh, Pa., and well known through his development of skylights and the solution of ventilation problems for many industrial plants and public buildings, died at his home at Sewickley, Pa., on Jan. 15. Mr. Waugh was born in Hedrick, Iowa, and attended Iowa State College, at Ames, Iowa. During Mr. Waugh's association with the H. H. Robertson Co. his skylights were developed to their present state of perfection. Some of his most notable installations are those on the Cadillac, Packard and Dodge Motor company plants in Detroit, the Indianapolis Union Station, and the Centennial Memorial Building at Springfield, Ill. During this period he also developed a double glazed skylight that is widely used on paper mills and in textile plants where drippage must be constantly guarded against.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Domestic Business Conditions Continue Almost Uniformly Favorable

Seasonal Declines Expected in January Fail to Appear—Outlook Is Particularly Bright—Chemical Prices Are Mounting, Although General Commodity Prices Are Relatively Stable

JANUARY almost always shows some let-up in industrial activity after the first rush of contract making and inventory re-stocking has subsided. This year, however, the month has been characterized by well-sustained business in practically all lines, and in many instances there have been increases over the preceding month. The Department of Commerce reports that figures which became available during the week ended Jan. 22, 1923, have confirmed this industrial improvement. Particularly has the better transportation situation favorably affected the shipment and distribution of many commodities. Retail sales have been of record proportions and current reports indicate that sales have been well maintained during January. General price levels have remained relatively stable, although increases in some groups and decreases in others have tended to bring these groups more in line with other commodities.

Chemical prices have shown a very sharp rise since the first of October and especially during January was the increase most marked. The total gain, as recorded by *Chem. & Met.'s* index of chemical prices, amounted to about 30 points. Almost half of this gain occurred during January, as will be seen from Fig. 1.

The Trend of Production

The index of production in the basic industries compiled by the Federal Reserve Board has also been rising rapidly since last August. A very slight recession was shown in December, although, on the whole, production was maintained at a level near the peak of 1920. The output of pig iron and coal continued to increase, but the production in certain industries, notably textiles, has shown some declines. Consumption of cotton by textile mills in December totaled 527,945 bales, or about 50,000 bales less than the very high record made in November.

Petroleum production in the week ended Jan. 27 has been estimated by the American Petroleum Institute to have amounted to 1,755,300 bbl. This is the highest rate of production ever recorded and is an increase of 18,400 bbl. over the preceding week.

Copper production in December reached 103,845,000 lb., the largest for any month since 1920. This compares with 18,595,000 lb. in December, 1921.

Current production figures in the heavy chemical industry are not avail-

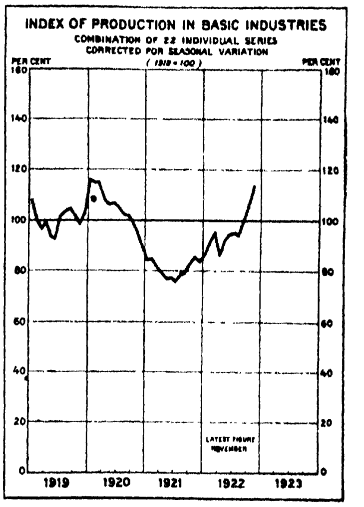

FIG. 2—FEDERAL RESERVE BOARD'S INDEX OF PRODUCTION

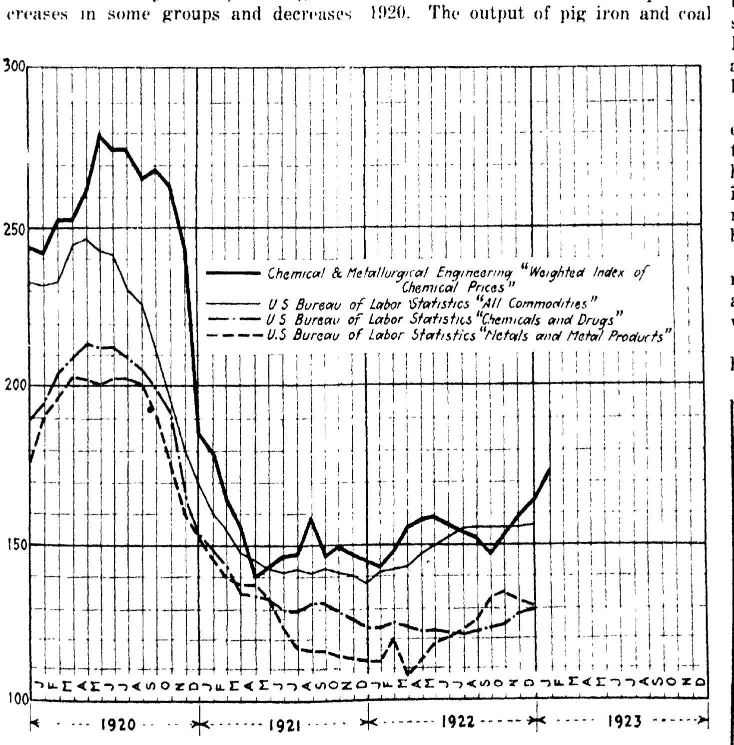

FIG. 1—WHOLESALE PRICES FOR CHEMICAL, METALLURGICAL AND ALLIED PRODUCTS

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

Last week	175.08
February, 1922	148
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

Included in this index are acetic, citric, hydrochloric, nitric, and sulphuric acids, ethyl and methyl alcohols, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, salt cake, soda ash, sulphur, benzene, aniline, and cottonseed and linseed oils.

able, but the manufacturers of alkali report that their plants are now operating at practically maximum capacity In the dye and fine chemical industries the improvement has been less general, but there is, nevertheless, substantial evidence of better business prospects.

Employment in December

The Bureau of Labor Statistics, in its reports on the volume of employment during December, states that 3,294 representative establishments in 43 manufacturing industries employed 1,587,708 employees, as compared with 1,551,080 in November. There was an increase of 2.4 per cent in the number of employees and of 3 per cent in the total payrolls.

Increases in the number of employees in December, 1922, as compared with the number of employees in identical establishments in November, were shown in 33 of the 43 industries, with decreases in the remaining 10 industries. Pottery, owing to the resumption of work after the settlement of the recent strike, shows the greatest increase, 29.9 per cent. Fertilizer plants, following a seasonal let-up in December, showed decreased employment of 11.4 per cent.

TABLE I—INDEX NUMBERS FOR WHOLESALE PRICES IN NOVEMBER AND DECEMBER, 1922

	1921 December	1922 November	1922 December
Price Index Numbers			
Wholesale prices:			
Department of Labor			
Farm products	120	143	145
Food, etc.	136	143	144
Cloths and clothing	180	192	194
Fuel and lighting	199	218	216
Metals and metal products	113	133	131
Building material	158	185	185
Chemicals and drugs	127	127	130
Housefurnishing goods	178	179	182
Miscellaneous	121	122	122
All commodities	140	156	156
Dun's (first of month)	136	153	153
Retail price, food	150	145	147

In 40 chemical works employing 14,025 workers in November there was an increase of 0.2 per cent in number on payroll and of 3.8 in amount of payroll. Twenty-eight petroleum refineries employed 41,903 employees in November and 42,693 in December, an increase of 1.9 per cent. Wage increases, however, raised the amount of their payrolls by 6.5 per cent.

Wholesale Prices

The Department of Labor wholesale price index showed no change in December, remaining at 156, the same as in November. Slight increases in farm products, foods, cloth and clothing, chemicals and housefurnishing goods were offset by declines in fuels and metals. Dun's index number also showed no change, while Bradstreet's declined 1 point. The retail food index increased again, reaching 147, the highest for any month of 1922. These index numbers are shown in Table I. The chemical, metallurgical and all commodity indexes are shown graphically on the preceding page (Fig. 1).

Disturbing Influences Result in Higher Prices in New York Chemical Market

Transportation and European Difficulties Have a Tendency to Maintain Strength Throughout the List—Manufacturers Reduce Quotations on Citric Acid—Arsenic Continues in Scant Supply

NEW YORK, Feb. 5, 1923.

THE growing shortage of freight cars has caused a pronounced scarcity of caustic soda and soda ash on the spot market and has also strengthened prices along the entire list. It is expected that the European disturbance will continue to affect German chemicals, and dealers in barium chloride, prussiate of soda, barium carbonate and sal ammoniac have not shown any inclination to sell at low prices.

Manufacturers of citric acid reduced prices to the level of imported material. Bleaching powder has been in very scarce supply at the works and second hands have been getting a premium for spot and prompt shipments. Oxalic acid was somewhat lower among producers. Sulphate of ammonia is quite scarce due to the recent heavy shipments to Japan. The demand for arsenic has again strengthened and resale stocks are rapidly diminishing. Prices for spot goods were materially higher. Caustic potash, carbonate of potash, chlorate and permanganate of potash continue along very firm lines.

Principal Price Changes

Alcohol—There were no important changes during the week. The 95 per cent methanol was quoted at \$1.21@\$1.23 per gal. in barrels, with 97 per cent at \$1.23@\$1.25. Denatured 188 proof No. 1 formula held around 38@40c. per gal. in drums.

Arsenic—The lowest price heard for resale stocks ranged around 15¾c. per lb. Recent heavy arrivals have been quickly sold.

Bichromate of Soda—The demand is running along moderately active lines with carload quantities quoted at 7½c. per lb. and lesser lots at 7¾@8c. f.o.b. works.

Bleaching Powder—Producers reported a heavily sold up condition at the works and quote the market at 2c. per lb. for large containers. Second hands have been getting up to 2½c. per lb. for prompt shipment goods in large drums and 2¾c. per lb. for export packages. Demand is exceptionally active.

Caustic Soda—The export inquiry is rather quiet, but prices are quite firm, due to the scarcity of spot goods. Domestic material is in very good demand and sales went through at \$3.75 per 100 lb. ex-store. Contracts continue at 2½c. per lb., basis 60 per cent f.o.b. works, in carload lots.

Citric Acid—Leading producers announced a reduction to a parity with imported goods. Prices range around 49c. for crystals and 50c. per lb. for powered. Demand is quite steady.

Copperas—Several transactions have been reported at \$21.50 per ton in barrels. Bulk material is somewhat lower at \$16.50 per ton f.o.b. works.

Formaldehyde—Producers continue to quote 16c. per lb. for carload lots f.o.b. works. Second hands were anxious to dispose of stocks and quoted down to 15½c. for 25-bbl. lots.

Lactic Acid—Leading producers report a regular demand from consumers for the various grades. The 44 per cent light was sold at 11c. per lb. in barrels, with 22 per cent light at 5c. per lb.

Nitrite of Soda—Several lots of imported material were on the market at 8½@8¾c. per lb. Domestic producers continue to quote 10@10½c. per lb., f.o.b works. The general market is irregular.

Salt Cake—The demand is rather steady, with quotations heard around \$25 per ton f.o.b. works for bulk. Spot material is in scarce supply around \$30 per ton.

Soda Ash—Spot material is quite scarce, due to transportation difficulties. Spot goods in single bags were held around \$1.75 per 100 lb., carload lots. Contracts at the works were quoted at \$1.20 per 100 lb., basis 48 per cent, single bags, carload lots.

Sulphate of Ammonia—The lowest quotation heard for prompt shipment ranged around \$3.85 per 100 lb., double bags, f.a.s. New York.

Coal-Tar Products

Aniline Oil—Several fair-sized sales were noted at 16½@17c. per lb. in drums on spot. Quotations in general held quite firm, with producers quoting 16c. per lb. at the works.

Benzene—Manufacturers report a steady call from consumers and quote the 90 per cent at 27c. per gal. in tanks and 32c. in drums. The pure material is quoted at 30c. in tanks and 35c. per gal. in drums. Deliveries have been materially improved.

Beta Naphthol—Although actual sales were not heavy, prices held quite steady at 24@25c. per lb. for technical goods. Sublimed material was quoted at 55@60c. per lb.

Carbazol—The general tone is somewhat irregular, with producers quoting around 75@80c. per lb.

Cresylic Acid—Spot stocks have been practically exhausted and producers announced a heavily sold up condition at the works. Several small lots of 95 and 97 per cent goods were offered among second hands up to \$1.75@\$1.80 per gal. Actual sales were small, due to the scarcity of supplies.

Phenol—Spot material is quite scarce and dealers are not anxious to dispose of any material under 35c. per lb. Imported good were quoted at 40c. per lb. for shipment.

Better Volume of Business in Chicago District

Revival of Consuming Interest Noted as Imported Chemicals Are Advanced

CHICAGO, Ill., Feb. 1, 1923.

Business in industrial chemicals continued good in this district and all factors reported a satisfactory volume. No great increase was to be noted, but business was steady, with most of it from consumers who were buying for their immediate or near future requirements. Prices held firm with only a few advances noted and these were mainly on imported items. The situation abroad is bad for the importer, as he has no assurance that his present stocks can be replaced.

Principal Price Changes

Caustic soda continued to move well in consuming channels, but the spot movement was not good. Ground 76 per cent soda was quoted on spot in ton lots at \$4.25 per 100 lb. and the solid in similar quantities at \$3.50. *Caustic potash* was very firm following the recent advance, and 8c. per lb. for the 88-92 per cent material was the best offer noted. *Soda ash* moved well and was unchanged at \$2.25 per 100 lb. for material in cooperage.

Potash alum was in good demand and only moderate lots were available for spot delivery. The iron-free lump was quoted at 4½@5c. per lb. and the powder at 5½@6c. Small sales of *ammonium carbonate* were reported with 9c. per lb. the best price named. *Ammonium chloride* was firm with a good demand reported. The white granular material was quoted at 8@8½c. per lb., with slightly better figures named on material for shipment from the East. *Barium compounds* were steady and unchanged in price. *Barium chloride* was offered in small quantities at \$110 per ton and the carbonate at \$90. *White arsenic* showed no signs of breaking and the small lots available on spot were held at 17c. per lb. *Blue vitriol* was firmer due to the strength of the metal, but it was still possible to purchase material at 6c. per lb. in less than carload lots. *Carbon bisulphide* was unchanged in price with small lots offered for spot delivery at 7½c. per lb. *Carbon tetrachloride* was firm and spot material was held at 10½@11c. per lb. *Formaldehyde* was quiet, but the price held firm at 17c. per lb. in single-barrel lots. Consumers apparently took on heavy supplies when the price was low and will not be in the market again for some time. *Furfural* was unchanged at 25c. per lb. in thousand-pound lots. *Glycerine* was quite firm and 18½c. per lb. for c.p. material in drums was the inside.

The price on *phosphoric anhydride* was reduced to 38c. per lb. in case lots of 1-lb. tins. *Potassium bichromate* was firm and was reported as moving well at 12½@13c. per lb. *Sodium bichromate* was also in good demand and was firm at 8½@9c. per lb. *Potassium cyanide* was slow and the price was unchanged at 55c. per lb. in single-case lots. *Yellow prussiate of potash* was offered in small or moderate lots at 40c. per lb. One small lot of the *red prussiate* was offered at 85c., but no quantity was available below 90c.

Linseed Oil and Turpentine

Boiled *linseed oil* was quoted higher at 98c. per gal. in single-drum lots at the close of today's market. The material continued to move very slowly to the consuming trade and only small transactions were reported.

Turpentine was lower today and pure gum spirits were quoted in single-drum lots at \$1.50 per gal. Like boiled oil, turpentine was in very poor demand and only very small quantities were moving.

Steel Mills to Operate at Physical Limits

Recent Buying Has Given Momentum to Carry Industry Along Even in a Quiet Market

PITTSBURGH, Feb. 2, 1923.

While there is still a very fair degree of activity in finished steel products in point of tonnage turnover in the open market, the curious buying movement of the past 2 months may be said to be over. In each of these months the independent steel producers as a whole sold much more steel than they shipped.

Practically all the mills are now well sold for the remainder of the present quarter, and some are oversold, while in no important product has the Steel Corporation much unsold tonnage for the half year. Many independents have a good backlog of business for second quarter. At the beginning of December, on the contrary, some mills did not have enough business to carry them through the month.

The plain outlook now is that the steel mills will operate substantially at the physical limit to about July 1. The physical limit will probably be made by labor supply rather than any other factor. The mills have had an active market for 2 months and have acquired what is sometimes called "momentum" to carry them along for several months during a relatively quiet market. This is not, however, a momentum that gradually yields to a decelerating influence. Rather it indicates a continuance of the pace of production. That is, if a mill is sold up fully for 2 months and enters business during 5 months at three-fifths of its current shipments, it rounds out the 5 months with its order book liquidated.

Price Advances

The old 2c. price on merchant steel bars may now be said to have disappeared entirely. It remains in the reckoning only in that the Steel Corporation does not seem to have made an "official" advance, though it has sold some tonnage at 2.10c. and would not promise an early delivery at 2c. if it sold at that price at all. Shapes and plates had previously advanced from 2c. to 2.10c., as already reported. News has leaked out that about Jan. 19 the American Steel & Wire Co. advanced its price on plain wire from 2.45c. to 2.55c. The company has not advanced nails from its \$2.70 level. Its prices are not readily ascertained, as it is not usually a seller, having a large order book. Early in January independents had advanced plain wire to 2.55c. and nails to \$2.80. They are making sales at the prices without difficulty.

Advances in manufactured steel products continue, reflecting higher costs of hot-rolled material. Chain advanced \$5 a ton early in January. In the past week cold-finished steel bars and ground shafting have advanced \$3 a ton, to 2.65c. and 3.05c. respectively, while spikes are up \$3 a ton on standard size, to 2.90c., and small spikes and boat and barge spikes are up \$5 a ton, to 3.50c. Rivets, instead of advancing, are still reported a trifle weak on the old price of 3c.

The predicted advance in sheets by independents has not occurred, but the market is lined up for an advance, with several mills out of the market, being fully sold for the quarter. Blue annealed is going more frequently at an advance. The market is 2.50@2.60c. on blue annealed, 3.35c. on black, 4.35c. on galvanized and 4.70@5c. on automobile sheets.

Coke and Pig Iron

The recent settlement of coal wage matters for another year may have been an influence in the decrease in tonnage turnover in steel products. It has not yet had much discernible influence in the matter of coal and coke prices, probably because transportation has been poorer in some districts, notably the Pittsburgh district, than in December. Steam coal is off a trifle in both Pittsburgh and Connellsville markets, but is well above the low points seen about the beginning of December. Connellsville furnace coke has not declined at all, being \$8@\$8.25 for spot or prompt. In other words, the liquidation in coke prices is still to come, but this may be deferred 2 or 3 weeks, on account of the continuance of good demand for coke for heating purposes. Buyers of pig iron evidently expect much lower coke prices and count on the decline having some influence on pig iron prices, for there is no forward buying to speak of, and the markets in practically all districts are dull.

Sales of 20,000 to 25,000 tons of Nova Scotia basic pig iron, high in phosphorus and low in manganese, have been made to Eastern steel works at several dollars a ton below the market for local iron and this will probably have an influence on the Eastern pig iron market. The Pittsburgh valley market has continued quiet, with prices not quotably changed, at \$27.50 for bessemer, \$25@\$26 for basic and \$27@\$28 for foundry f.o.b. valley furnaces, freight to Pittsburgh being \$1.77.

Current Prices in the New York Market

FOR CHEMICALS, OILS AND ALLIED PRODUCTS

Although these prices are for the spot market in New York City, a special effort has been made to report the American manufacturer's quotations whenever available. In many instances these are for material f.o.b. works or on a contract basis and these prices are so designated. Quotations on imported and resale stocks are reported when of sufficient importance to have a material effect on the market. Prices quoted in these columns apply to large quantities in original packages.

General Chemicals

Acetic anhydride, 85%, drums	lb	$0 39 -	$0 41

Nickel salts, single, bbl	lb	11 -	11½
Phosgene		60	75
Phosphorus, red, cases	lb	35	40
Phosphorus, yellow, cases	lb	30 -	35
Potassium bichromate, casks	lb	09¾-	10
Potassium bromide, gran, bbl	lb	17 -	23
Potassium carbonate, 80-85%, calcined, casks	lb	06 -	06¼
Potassium chlorate, powd.	lb	07½ -	08
Potassium cyanide, drums.	lb	.47 -	80
Potassium hydroxide (caustic potash) drums	100 lb	7 25 -	7 50
Potassium iodide, cases	lb	3 60 -	3.70
Potassium nitrate, bbl	lb	06½ -	07
Potassium permanganate, drums	lb	17½	18
Potassium prussiate, red, casks	lb	85	90
Potassium prussiate, yellow, casks	lb	38	39
Salammoniac, white, gran, casks, imported	lb	06½	06¾
Salammoniac, white, gran, bbl., domestic	lb	08	08½
Gray, gran, casks	lb	08½	08¾
Salsoda, bbl	100 lb	1 20	1 40
Salt cake (bulk)	ton	25 00	27 00
Soda ash, light, 58% flat, bags, contract	100 lb	1 60	1 67
Soda ash, light, basis, 48%, bags, contract, f o b wks	100 lb	1 20	1 30
Soda ash, light, 58%, flat, bags, resale	100 lb	1 75 -	1 80
Soda ash, dense, bags, contract, basis 48%	100 lb	1 17½	1 20
Soda ash, dense, in bags, resale	100 lb	1 85 -	1 90
Soda, caustic, 76%, solid, drums, f a s	100 lb	3 45 -	3 70
Soda, caustic, 76%, solid, drums, contract	100 lb	3 35	3 40
Soda, caustic, basis 60%, wks, contract	100 lb	2 50	2 60
Soda, caustic, ground and flake, contracts	100 lb	3 80 -	3 90
Soda, caustic, ground and flake, resale	100 lb	4 00 -	4 15
Sodium acetate, works, bags	lb	06¾-	07½
Sodium bicarbonate, bbl	100 lb	1 75 -	1 85
Sodium bichromate, casks	lb	07½-	08
Sodium bisulphate (niter cake)	ton	6 00 -	7.00
Sodium bisulphite, powd, U S P, bbl	lb	.04½-	.04¾
Sodium chlorate, kegs	lb	.06½-	.07
Sodium chloride	long ton	12 00 -	13.00
Sodium cyanide, cases	lb.	19 -	.23
Sodium fluoride, bbl	lb	09 -	.10
Sodium hyposulphite, bbl	lb	03 -	.03½
Sodium nitrite, casks	lb.	08½-	.09
Sodium peroxide, powd, cases	lb	28 -	.30
Sodium phosphate, dibasic, bbl	lb	03½-	04
Sodium prussiate, yel. drums	lb	19 -	19½
Sodium silicate (40°, drums)	100 lb	80 -	1 15
Sodium silicate (60°, drums)	100 lb.	2 00 -	2 25
Sodium sulphide, fused, 60-62% drums	lb.	04½-	.04¾
Sodium sulphite, crys., bbl.	lb.	03½-	.03¾
Strontium nitrate, powd, bbl.	lb.	09½-	.10½
Sulphur chloride, yel drums	lb.	04½-	.05
Sulphur, crude	ton	18 00 -	20 00½
Sulphur dioxide, liquid, cyl.	lb.	.08 -	.08
Sulphur, flour, bbl.	100 lb.	2.50 -	3.15
Sulphur, roll, bbl	100 lb.	$2 15 -	$2 20
Talc—imported, bags	ton	30 00 -	40 00
Talc—domestic powd, bags	ton	18 00 -	25 00
Tin bichloride, bbl	lb	.11 -	11½
Tin oxide, bbl.	lb.	.45 -	.47
Zinc carbonate, bags	lb.	.14 -	.14½
Zinc chloride, gran, bbl	lb	07 -	07½
Zinc cyanide, drums	lb	42 -	44
Zinc oxide, XX, bbl	lb	07½-	08
Zinc sulphate, bbl	100 lb.	2 75 -	3.00

Coal-Tar Products

Alpha-naphthol, crude, bbl	lb	$0 85 -	$0 95
Alpha-naphthol, ref., bbl.	lb	1 05 -	1 10
Alpha-naphthylamine, bbl.	lb	28 -	30
Aniline oil, drums	lb	.16½-	17
Aniline salts, bbl	lb	.24 -	25
Anthracene, 80%, drums	lb.	75 -	1 00
Anthracene, 80%, imp, drums, duty paid	lb.	.65 -	70
Anthraquinone, 25%, paste, drums	lb	70 -	75
Benzaldehyde U.S P, carboys	lb.	1 35 -	1.40
Benzene, pure, water-white, tanks and drums	gal.	30 -	35
Benzene, 90%, tanks & drums	gal.	26 -	32
Benzene, 90%, drums, resale	gal.	32 -	.34
Benzidine base, bbl	lb.	85 -	.90
Benzidine sulphate, bbl	lb	.75 -	.80
Benzoic acid, U S P, kegs	lb	72 -	.75
Benzoate of soda, U S P, bbl	lb.	57 -	.65
Benzyl chloride, 95-97%, ref., drums	lb.	25 -	.27
Benzyl chloride, tech, drums	lb.	20 -	.23
Beta-naphthol, subl, bbl	lb.	55 -	60
Beta-naphthol, tech, bbl	lb.	25 -	26
Beta-naphthylamine, tech	lb.	1 00 -	1 25
Carbazol, bbl	lb	75 -	.90
Cresol, U S P, drums	lb	.26 -	.28
Ortho-cresol, drums	lb	.24 -	.26
Cresylic acid, 97%, resale, drums	gal	1.75 -	1 85
95-97%, drums, resale	gal	1 75 -	1 85
Dichlorbenzene, drums	lb	07 -	.09
Diethylaniline, drums	lb	50 -	.60
Dimethylaniline, drums	lb	40 -	.41
Dinitrobenzene, bbl	lb	20 -	.22
Dinitroclorbenzene, bbl	lb	22 -	.23
Dinitronaphthalene, bbl	lb	30 -	.32
Dinitrophenol, bbl	lb	35 -	.40
Dinitrotoluene, bbl	lb	22	.24
Dip oil, 25%, drums	gal.	25 -	.30
Diphenylamine, bbl	lb	54 -	.56
H-acid, bbl	lb	.75 -	80
Meta-phenylenediamine, bbl.	lb	95 -	1.00
Michlers ketone, bbl	lb	3 25 -	3 75
Monochlorbenzene, drums	lb.	08 -	10
Monoethylaniline, drums	lb.	95 -	1 10
Naphthalene, crushed, bbl	lb.	05½-	06
Naphthalene, flake, bbl	lb.	.06 -	.06½
Naphthalene, balls, bbl	lb	07 -	.07½
Naphthionate of soda, bbl	lb	.58 -	65
Naphthionic acid, crude, bbl.	lb	.60 -	.65
Nitrobenzene, drums	lb	.10 -	.12
Nitro-naphthalene, bbl	lb.	.30 -	.35
Nitro-toluene, drums	lb.	.15 -	.17
N-W acid, bbl	lb.	1.15 -	1.20
Ortho-amidophenol, kegs	lb	2.30 -	2.35
Ortho-dichlorbenzene, drums	lb	17 -	.20
Ortho-nitrophenol, bbl	lb.	.90 -	.92
Ortho-nitrotoluene, drums	lb.	.12½-	.14
Ortho-toluidine, bbl	lb	14 -	.16
Para-amidophenol, base, kegs	lb	1.25 -	1.30
Para-amidophenol, HCl, kegs	lb.	1.30 -	1.35
Para-dichlorbenzene, bbl	lb.	.17	.20
Paranitraniline, bbl	lb.	.73 -	.75
Para-nitrotoluene, bbl	lb.	.55 -	.65
Para-phenylenediamine, bbl	lb.	1 50 -	1.55
Para-toluidine, bbl	lb	.85 -	.90
Phthalic anhydride, bbl	lb	35 -	.38
Phenol, U S P, drums	lb	35 -	.37
Picric acid, bbl	lb	.20 -	.22
Pyridine, dom, drums	gal.	nominal	
Pyridine, imp., drums	gal.	3 00 -	3.10
Resorcinol, tech., kegs	lb	1 50 -	1.55
Resorcinol, pure, kegs	lb	2 00 -	2.10
R-salt, bbl.	lb	55 -	.60
Salicylic acid, tech, bbl	lb	40 -	.42
Salicylic acid, U S P, bbl	lb	45 -	.47
Solvent naphtha, water-white, drums	gal.	.37 -	.40
Crude, drums	gal.	22 -	.24
Sulphanilic acid, crude, bbl.	lb.	20 -	.22
Thiocarbanilide, kegs	lb.	35 -	.38
Toluidine, kegs	lb.	1 20 -	1.30
Toluidine, mixed, kegs	lb	.30 -	.35
Toluene, tank cars	gal.	.35 -	.37
Toluene, drums	gal.	.40 -	.43
Xylidines drums	lb.	.40 -	.45
Xylene, pure, drums	gal.	.45 -	.50
Xylene, com., drums	gal.	.40 -	.42
Xylene, com., tanks	gal.	.30 -	......

Naval Stores

Rosin B-D, bbl.	280 lb	$5 75 –	
Rosin E-I, bbl.	280 lb.	5 90 –	
Rosin K-N, bbl.	280 lb.	6 10 –	$6 35
Rosin W.G.-W.W., bbl.	280 lb	7 75 –	8 25
Wood rosin, bbl.	280 lb	6 25 –	
Turpentine, spirits of, bbl.	gal.	1.43 –	1 45
Wood, steam dist., bbl.	gal	1.35 –	
Wood, dest dist., bbl	gal.	1.25 –	
Pine tar pitch, bbl	200 lb	.... –	6 00
Tar, kiln burned, bbl.	500 lb.	. –	12 00
Retort tar, bbl.	500 lb	. –	11 00
Rosin oil, first run, bbl.	gal	43 –	
Rosin oil, second run, bbl.	gal	47 –	
Rosin oil, third run, bbl	gal	.53 –	
Pine oil, steam dist	gal.	... –	90
Pine oil, pure, dest dist.	gal	.. –	85
Pine tar oil, ref	gal.	... –	46
Pine tar oil, crude, tanks f.o.b Jacksonville, Fla	gal	.. –	35
Pine tar oil, double ref., bbl.	gal.	–	75
Pine tar, ref, thin, bbl.	gal	–	25
Pinewood creosote, ref, bbl	gal	–	52

Vegetable Oils

Castor oil, No. 3, bbl	lb	$ 12¼ –	$ 12½
Castor oil, AA, bbl.	lb.	.12¾ –	13
Chinawood oil, bbl	lb.	.17 –	17½
Coconut oil, Ceylon, bbl.	lb.	.09¼ –	9½
Coconut oil, Cochin, bbl	lb	.09¾ –	10
Corn oil, crude, bbl	lb	11¼ –	11½
Cottonseed oil, crude (f o.b mill), tanks	lb	09¾ –	10
Summer yellow, bbl.	lb.	12½	12¾
Winter yellow, bbl	lb	.13 –	13¼
Linseed oil, raw, car lots, bbl.	gal	92	93
Raw, tank cars (dom).	gal.	87 –	88
Boiled, 5-bbl lots (dom)	gal	96 –	97
Olive oil, denatured, bbl.	gal.	1 10 –	1 15
Palm, Lagos, casks.	lb	08 –	08¼
Palm kernel, bbl.	lb.	08¼ –	09
Peanut oil, crude, tanks (mill)	lb.	13½ –	13¾
Peanut oil, refined, bbl	lb.	16 –	16¼
Rapeseed oil, refined, bbl.	gal.	85 –	86
Rapeseed oil, blown, bbl.	gal.	90 –	91
Soya bean (Manchurian), bbl	lb.	11½	
Tank, f.o.b. Pacific coast	lb	.10 –.	

Fish Oils

Menhaden, light pressed, bbl	gal.	$0.60 –	
White bleached, bbl	gal.	.64 –	65
Blown, bbl	gal.	.68 –	69
Whale No. 1 crude, tanks, coast	lb	.06 –	06½

Dye & Tanning Materials

Divi-divi, bags.	ton	$38 00 –	$39 00
Fustic, sticks	ton	30 00 –	35 00
Fustic, chips, bags.	lb	04 –	05
Logwood, sticks	ton	28 00 –	30 00
Logwood, chips, bags.	lb	02½ –	03½
Sumac, leaves, Sicily, bags.	ton	65 00 –	
Sumac, ground, bags	ton	55 00 –	60 00
Sumac, domestic, bags.	ton	35 00 –	
Tapioca flour, bags.	lb	03½	05

EXTRACTS

Archil, conc, bbl.	lb	$0 17	$0 18
Chestnut, 25% tannin, tanks	lb	02 –	03
Divi-divi, 25% tannin, bbl	lb	04 –	05
Fustic, crystals, bbl	lb	20 –	22
Fustic, liquid, 42°, bbl	lb	08 –	09
Gambier, liq, 25% tannin, bbl.	lb.	08 –	09
Hematine crys., bbl.	lb.	.14 –	18
Hemlock, 25% tannin, bbl	lb	.04 –	05
Hypernic, solid, drums	lb	24 –	26
Hypernic, liquid, 51°, bbl.	lb.	14 –	17
Logwood, crys., bbl.	lb	19 –	20
Logwood, liq., 51°, bbl.	lb	09 –	10
Quebracho, solid, 65% tannin, bbl	lb.	.04½ –	05
Sumac, dom., 51°, bbl.	lb.	.06¼ –	07

Waxes

Bayberry, bbl.	lb	$0 28 –	$0 30
Beeswax, refined, dark, bags	lb.	30 –	32
Beeswax, refined, light, bags	lb	.34 –	35
Beeswax, pure white, cases.	lb	.40 –	41
Candelilla, bags.	lb.	.34 –	.35
Carnauba, No. 1, bags.	lb.	.38 –	.40
No. 2, North Country, bags	lb.	.23½ –	.24
No. 3, North Country, bags	lb.	.17½ –	.18
Japan, cases	lb.	.15 –	15½
Montan, crude, bags.	lb.	.03¾ –	04
Paraffine, crude, match, 105-110 m.p.	lb.	.04 –	04½
Crude, scale 124-126 m.p., bags	lb.	.02½ –	02¾
Ref., 118-120 m p., bags.	lb.	.03¼ –	.03½
Ref., 125 m.p., bags	lb.	.03½ –	.03¾
Ref. 128-130 m.p, bags.	lb.	.04 –	.04¼
Ref., 133-135 m p, bags.	lb.	.04½ –	.04¾
Ref., 135-137 m p., bags.	lb.	.05 –	.05¼
Stearic acid, sgle pressed, bags	lb.	.10 –	.10½
Double pressed, bags.	lb.	.10½ –	.10¾
Triple pressed, bags	lb.	.11 –	.11½

Fertilizers

Ammonium sulphate, bulk, f.o.b. works	100 lb.	$3.20 –	$3 25
F.a.s. double bags	100 lb	3.85 –	3.95
Blood, dried, bulk	unit	4 60 –	.....
Bone, raw, 3 and 50, ground	ton	30.00 –	35.00
Fish scrap, dom., dried, wks.	unit	5.00 –	5.10
Nitrate of soda, bags	100 lb.	2.60 –	2.65
Tankage, high grade, f.o.b. Chicago	unit	4.70 –	4.80

Phosphate rock, f.o b. mines, Florida pebble, 68-72%	ton	$3 50 –	$4 00
Tennessee, 78-80%	ton	7 00 –	8 00
Potassium muriate, 80%, bags	ton	35 55 –	38 25
Potassium sulphate, bags	unit	1 00 –	

Crude Rubber

Para—Upriver fine	lb	$0 34½	$0 35
Upriver coarse	lb	28½ –	28
Upriver caucho ball	lb	29¾	30
Plantation—First latex crepe	lb	35¼	35½
Ribbed smoked sheets	lb	35¼ –	35½
Brown crepe, thin, clean	lb	31 –	32
Amber crepe No. 1	lb	31 –	32

Miscellaneous Materials

Asbestos, crude No. 1, f.o b., Quebec.	sh. ton	$450 00 –	$550 00
Asbestos, shingle, f o.b., Quebec	sh. ton	60 00 –	80 00
Asbestos, cement, f.o.b., Quebec	sh ton	15 00 –	17 00
Barytes, grd, white, f.o.b. mills, bbl.	net ton	16 00 –	20 00
Barytes, grd., off-color, f o b. mills bulk.	net ton	13 00 –	21 00
Barytes, floated, f o b St Louis, bbl.	net ton	24 00 –	28 00
Barytes, crude f o b mines, bulk	net ton	8 50 –	9 00
Casein, bbl, tech.	lb	11 –	12
China clay (kaolin) crude, f.o b. Ga.	net ton	7 00 –	9 00
Washed, f o.b. Ga.	net ton	8 00 –	9 00
Powd, f.o b Ga.	net ton	13 00 –	20 00
Crude f.o b Va	net ton	8 00 –	12 00
Ground, f o b. Va.	net ton	13 00 –	20 00
Imp., lump, bulk.	net ton	15 00 –	20 00
Imp., powd	net ton	45 00 –	50 00
Feldspar, No. 1 pottery	long ton	6 00 –	7 00
No 2 pottery	long ton	5 00 –	5 50
No 1 soap	long ton	7 00 –	7 50
No. 1 Canadian, f.o b mill	long ton	25 00 –	27 00
Graphite, Ceylon, lump, first quality, bbl	lb	06 –	.06½
Ceylon, chip, bbl.	lb.	05 –	05½
High grade amorphous crude	ton	35 00 –	50 00
Gum arabic, amber, sorts, bags	lb	15 –	16
Gum tragacanth, sorts, bags	lb	50 –	60
No 1, bags	lb	1 75 –	1 80
Kieselguhr, f o.b. Cal.	ton	40 00	42 00
F o b N Y.	ton	50 00 –	55 00
Magnesite, crude, f o b Cal	ton	14 00 –	15 00
Pumice stone, imp, casks	lb	03 –	05½
Dom, lump, bbl	lb	05	05½
Dom, ground, bbl	lb	06 –	07
Shellac, orange fine, bags	lb	84 –	85
Orange superfine, bags	lb	86 –	87
A C garnet, bags.	lb.	81 –	82
T N, bags	lb	82 –	83
Silica, glass sand, f o b. Ind	ton	2 00 –	2 50
Silica, sand blast, f o b Ind	ton	2 50	5 00
Silica, amorphous, 250-mesh, f.o b Ill	ton	17 00 –	17 50
Silica, bldg. sand, f o b Pa	ton	2 00 –	2 75
Soapstone, coarse, f.o.b. Vt, bags	ton	7 00	8 00
Talc, 200 mesh, f o.b., Vt, bags	ton	6 50 –	9 00
Talc, 200 mesh, f.o.b Ga, bags	ton	7 00 –	9 00
Talc, 200 mesh, f o.b. Los Angeles, bags.	ton	16 00 –	20 00

Refractories

Bauxite brick, 56% Al_2O_3, f o b Pittsburgh	ton	$45-50
Chrome brick, f o b Eastern shipping points	ton	50–52
Chrome cement, 40-50% Cr_2O_3	ton	23–27
40-45% Cr_2O_3, sacks, f.o.b Eastern shipping points	ton	23.00
Fireclay brick, 1st. quality, 9-in. shapes, f o.b Ky wks.	1,000	40–46
2nd quality, 9-in. shapes, f o b wks.	1,000	36–41
Magnesite brick, 9-in straight (f o b. wks)	ton	65 68
9-in arches, wedges and keys.	ton	80 85
Scraps and splits	ton	85
Silica brick, 9-in sizes, f o b Chicago district	1,000	48–50
Silica brick, 9-in. sizes, f o b. Birmingham district	1,000	48 50
F o.b. Mt. Union, Pa	1,000	42 44
Silicon carbide refract brick, 9-in	1,000	1,100 00

Ferro-Alloys

Ferrotitanium, 15-18% f o b. Niagara Falls, N Y	ton	$200 00 –	$225 00
Ferrochromium, per lb. of Cr, 6-8% C	lb.	11½	11¾
4-6% C	lb.	.12 –	13
Ferromanganese, 78-82% Mn, Atlantic seabd. duty paid	gr. ton	105.00 –	107 50
Spiegeleisen, 19-21% Mn.	gr ton	35 00 –	37 00
Ferromolybdenum, 50-60% Mo, per lb. Mo.	lb.	1.90 –	2.15
Ferrosilicon, 10-15%	gr ton	38.00 –	40 00
50%	gr. ton	80.00 –	85.00
75%	gr. ton	150.00 –	160.00
Ferrotungsten, 70-80%, per lb. of W	lb.	$0.90 –	$0.95
Ferro-uranium, 35-50% of U per lb of U	lb.	6.00 –	....
Ferrovanadium, 30-40%, per lb. of V	lb	3 50 –	4.00

Ores and Semi-finished Products

Bauxite, dom crushed, dried, f o b. shipping points	ton	$6 50 –	$8 75
Chrome ore, Calf concentrates, 50% min Cr_2O_3	ton	22 00 –	23 00
C i f. Atlantic seaboard	ton	18 50 –	19 00
Coke, fdry, f o b ovens	ton	9 25 –	9 50
Coke, furnace, f o b ovens	ton	8 00 –	8 50
Fluorspar, gravel, f o b. mines, New Mexico	ton	17 50 –	
Fluorspar, No 2 Lump—Ky & Ill mines	ton	25 00	
Ilmenite, 52% TiO_2	lb	01½ –	01½
Manganese ore, 50% Mn, c i f Atlantic seaport	unit	30 –	
Manganese ore, chemical (MnO_2)	ton	75 00 –	80 00
Molybdenite, 85% MoS_2, per lb MoS_2, N. Y.	lb	70	75
Monazite, per unit of ThO_2, c i f, Atl seaport	lb	06 –	.08
Pyrites, Span, fines, c.i f Atl seaport	unit	11½ –	12
Pyrites, Span, furnace size, c i f. Atl seaport	unit	.11½ –	12
Pyrites, dom. fines, f o.b. mines, Ga	unit	12	
Rutile, 95% TiO_2	lb.	.12 –	....
Tungsten, scheelite, 60% WO_3 and over, per unit WO_3	unit	8 00 –	8.50
Tungsten, wolframite, 60% WO_3 and over, per unit WO_3	unit	7 50 –	8 00
Uranium ore (carnotite) per lb of U_3O_8	lb	3 50 –	3 75
Uranium oxide, 96%, per lb U_3O_8	lb	2 25 –	2 50
Vanadium pentoxide, 99%	lb	12 00 –	14 00
Vanadium ore, per lb. V_2O_5	lb	1 00 –	
Zircon, washed, iron free, f.o.b. Pablo, Fla	lb	04½ –	13

Non-Ferrous Materials

	Cents per Lb.
Copper, electrolytic	15 00
Aluminum, 98 to 99%	22 00-23.00
Antimony, wholesale, Chinese and Japanese	7 15-7.50
Nickel, virgin metal	25 00-27.00
Nickel, ingot and shot	29 00
Monel metal, shot and blocks	32.00
Monel metal, ingots	38 00
Monel metal, sheet bars	45 00

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

RITCHIE—The Arkansas Pipe Line & Navigation Co., Smackover, organized with a capital of $5,000,000, is planning for the construction of a new oil storage and distributing plant in the vicinity of Ritchie. The initial tankage installation will consist of nine 20,000-bbl. and four 55,000 bbl steel tanks. A similar plant is also contemplated at New Orleans, La. Grant Stebbins is president.

PINE BLUFF—The Pine Bluff Refining Co is planning for the immediate installation of additional equipment at its local refining, including pressure stills and other apparatus, estimated to cost close to $100,000.

SMACKOVER—F. M. Lege, Jr., and associates, Dallas, Tex., have organized a company to construct and operate a new oil storage and distributing plant at Lege in the Smackover district, consisting of an initial capacity of 5,500,000 bbl., estimated to cost in excess of $1,500,000, including operating equipment. A total of sixteen steel tanks will be installed.

California

SOUTH SAN FRANCISCO—The Metal & Thermit Corp., 120 Broadway, New York, manufacturer of Thermit welding apparatus, chemical and metal products has plans in progress for the erection of a new local plant on Swift St., where a site of 11 acres is available. The works will consist of a number of buildings, with main rolling mill, estimated to cost in excess of $1,000,000, with machinery. The Engineering Department, New York office is in charge. E. W. Kardos is district manager, with office on Swift St., South San Francisco.

COALINGA—The Continental Petroleum & Refining Co is arranging for the immediate construction of ten gasoline refining plants in different points of the San Joaquin Valley, estimated to cost close to $1,000,000.

FRESNO—The Tyre Brothers Glass Co., 162 J St., is planning for the erection of a new building at its works to cost about $27,000. Trewhitt & Shields, Rowell Bldg., are architects.

YUBA CITY—The King's Food Products Co., Salem, Ore., is negotiating with the local Chamber of Commerce for a site for the erection of a new hydrating plant, with initial unit estimated to cost approximately $100,000, with machinery. A number of sites are said to be under consideration. R. G. Grant is representative for the company.

NAPA—The Mercury Oil Co. will commence the immediate erection of a new oil storage and distributing plant at East Napa, estimated to cost approximately $35,000.

ANTIOCH—The Paraffine Companies, Inc., 34 1st St., San Francisco, will call for bids early in February for the erection of a new plant building at Antioch, estimated to cost close to $40,000. Leland Rosener, Insurance Bldg., San Francisco, is architect.

Florida

SOUTH JACKSONVILLE—C. S. Burgess, 423 Cornelia St., is considering the establishment of a local plant for the production of oils and extracts from citrus fruits. Inquiries are being made for suitable machinery.

Idaho

PAYETTE—Danney & Co. have tentative plans under consideration for the rebuilding of their fruit evaporator plant, recently destroyed by fire with loss approximating $35,000.

Illinois

CHICAGO—L. Mitchell & Co., 1311 East 61st St., manufacturers of washing compounds, chemical products, etc., have purchased property, 225x300 ft. at Ellis Ave. and 83rd St., as a site for a new plant. No date for erection has as yet been set, and tentative plans only will be developed for the present. Frederick G. Mitchell is head.

CICERO—The American 3-Way Prism Co., 1305 South 55th Ct., manufacturer of glass products, has tentative plans under consideration for the erection of a new 1-story plant at Roosevelt Ave. and 65th Ct., 215x300 ft. An architect to prepare detailed drawings will be selected in the near future. C. H. Paschall is president.

Indiana

SEYMOUR—The Blish Milling Co. has plans in preparation for the erection of a new plant for the manufacture of oils from soy beans. A complete extraction works will be installed. The plant is estimated to cost close to $35,000, including machinery. John A. Shields is secretary.

Iowa

BURLINGTON—The Burlington Glass Co., 315 Tama Bldg., is considering plans for the erection of a new plant on North Main St., to be 1- and 2-story, 150x150 ft., estimated to cost approximately $250,000, including machinery. W. A. Rayburn is president.

Louisiana

LAFAYETTE—The Star Salt Co. has commenced the construction of a new plant at its works, to be equipped primarily for the evaporation of salt from the brine as pumped from the wells. It will have an initial capacity of about 200 tons per week, and is estimated to cost in excess of $55,000. John J. Kean is general manager.

Maryland

PINESBURG—The Keystone Limestone Co. has acquired the local limestone properties of the Potomac Valley Stone & Lime Co., Pinesburg, near Hagerstown, comprising about 165 acres of land, for a consideration of $65,000, and plans for the installation of plant and extensive operations.

HAGERSTOWN—The Hagerstown Lime & Chemical Co. is perfecting plans for the construction of its proposed local plant for the manufacture of agricultural lime and kindred products, and will call for construction bids in about 30 days. The plant will include a complete grinding and pulverizing works, with daily capacity of about 100 tons. J. S. Myers is president.

Michigan

LUDINGTON—The Morton Salt Co., 80 East Jackson Blvd., Chicago, Ill., has acquired the local plant and property of the Stearns Salt & Lumber Co., with capacity of 500,000 bbl. per annum. The purchasing company also operates a plant at Ludington, as well as at Port Huron, and plans to construct a large addition to the Ludington works, discontinuing operations at the Stearns plant. The plant of the Morton company has a present rated capacity of 1,000,000 bbl per year.

RIVER ROUGE—The Ford Motor Co., Highland Park, is taking bids for the construction of a new 1-story foundry at River Rouge, to be used for automotive casting production. Albert Kahn, 1000 Marquette Bldg., Detroit, is architect.

MANISTEE—The Filer Fibre Co., Filer City (recently incorrectly noted under Manistee, Mass.) has construction under way on a new local plant and will commence the machinery installation at an early date. The mill will be equipped to give employment to about 100 operatives. M. Oberdorfer is vice-president.

Mississippi

GULFPORT—The Gulf Coast Refining Co. has tentative plans under consideration for the construction of an addition to its local plant for considerable increase in production.

Missouri

FLAT RIVER—The Federal Lead Co. is reported to be planning for the construction of a new mill in the Dobson section, vicinity of Hockerville, Okla., where property has recently been acquired. The company also has plans under consideration for taking over the Bunker Hill properties in this same district.

KANSAS CITY—The Phillips-Morgan Estates, 607 Ridge Bldg., has plans in progress for the construction of a new paper mill, to consist of two main buildings, each 50x220 ft., estimated to cost close to $70,000. The general contract will be handled by the D. H. Greene Construction Co., same address. L. L. Morgan is president.

New Jersey

BAYONNE—The Ingram-Richardson Mfg. Co., Beaver Falls, Pa., manufacturer of enameled iron signs, will soon commence the erection of a new plant at Bayonne, comprising a main 1-story building, 181x325 ft., estimated to cost more than $60,000, with equipment. The A. M. Allen Co., 7016 Euclid Ave., Cleveland, O., is architect. Ernest Richardson is vice-president and treasurer.

NEWARK—The Martin Metals Corp. has leased a portion of the 4-story building at 115-17 Monroe St., owned by the Foster Engineering Co., for the establishment of a new foundry for the manufacture of aluminum and other metal castings.

NEWARK—The Nickelsburg Brothers Co., Meadow Ave., near the Lincoln Highway, has tentative plans under consideration for the enlargement of its leather tanning and manufacturing plant for considerable increase in capacity. The company has recently been disposing of a preferred stock issue of $1,000,000, a portion of the proceeds to be used for the proposed expansion.

TRENTON—The Reading Rubber Co., recently organized under state laws with a capital of $250,000, with initial paid-in capital of $51,000, has preliminary plans under way for the erection of a new plant on local site, replacing its present works at Kutztown, Pa. Negotiations are said to be in progress for the purchase of the land. The company is headed by Frank C. Myers, Trenton, Samuel H. Bell, Reading, Pa., and Jesse P. Stiles, Allentown, Pa. It is represented by Maxwell A. Kraemer, American Mechanic Bldg., Trenton.

BAYONNE—The National Sulphur Co., 80 Maiden Lane, New York, announces that the addition to its plant at North Akron, O., which was reported in these columns last week, is for the purpose of increased operations in that city and it is not the company's intention to vacate or lessen in any way its activities at the present works in Bayonne.

TRENTON—Officials of the Traveler Rubber Co., Bethlehem, Pa., headed by Guy de la Rigaudiere, president, have acquired a substantial interest in the United & Globe Rubber Co., Prospect and Frazier Sts., Trenton, and have organized a new company under the same name, with larger capitalization, to take over and operate the present business, devoted to the manufacture of mechanical rubber goods, automobile tires, etc. Extensions and improvements in the works are under consideration. John S. Broughton, president of the former organization, has been elected chairman of the board; Mr. de la Rigaudiere, president; and Victor Durand, Jr., 1st vice-president.

New York

LONG ISLAND CITY—The A. C. Horn Co., Bodine St., manufacturer of waterproofing products, technical coatings, etc., has purchased property on Hancock St., near 14th St., approximating 30,000 sq.ft., for proposed extensions.

HUDSON—The Knickerbocker Portland Cement Co. has awarded a contract to the Turner Construction Co., 242 Madison Ave., New York, for foundations and other work in connection with an addition to its local cement mill.

BUFFALO—The Williams Gold Refining Co., 2978 Main St., has work under way on extensions and improvements in its plant, estimated to cost about $15,000.

WATERFORD—The Goodyear Tire & Rubber Co., Akron, O., has acquired local property, heretofore occupied by the Beaver Mills Co., with option to purchase, for the establishment of a new branch plant for the manufacture of tires and other rubber products.

NEW YORK—The International Paper Co., 30 Broad St., has tentative plans under consideration for the construction of a large paper mill and hydro-electric power plant for operating service, at Grand Falls, N. B., estimated to cost in excess of $5,000,000.

Ohio

CLEVELAND—The Forest City Foundry & Mfg. Co., 1220 Main Ave., N. W., special-

izing in the production of small gray-iron castings, has tentative plans under consideration for the erection of a new 1-story foundry at Maywood Ave. and West 90th St., estimated to cost close to $400,000, with equipment. Albert Gerdum is president.

Oklahoma

TONKAWA—The Champlin Oil & Refining Co., Enid, Okla., has acquired a tract of local property, comprising about 45 acres of land, as a site for the construction of a new oil refining plant. Plans will be prepared at early date.

ARDMORE—The Hewitt Refining Co., recently organized with headquarters at Ardmore, is perfecting plans for the immediate erection of a new oil-refining plant on site secured at Wilson, near Ardmore, with initial capacity of about 1,500 bbl. per day. It is estimated to cost in excess of $200,000, with machinery. C. E. Sykes is president, and Ross W. Coe, secretary and treasurer.

TONKAWA—The Golden Rule Refining Co., Wichita, Kan., is planning for the construction of a new local oil refinery, estimated to cost approximately $100,000. A tract of property has been purchased.

TONKAWA—The Constantin Refining Co., Tulsa, has plans in progress for the construction of a new refining plant on 50-acre tract of land here, lately acquired. The refinery will be used for the production of refined petroleum, lubricating oils, etc.

Pennsylvania

PHILADELPHIA—The Philadelphia Paper Mfg. Co., River Rd., has awarded a general contract to the J. S. Rogers Co., Drexel Bldg., for the construction of a new 5-story building at Randolph and Willow Sts., estimated to cost approximately $225,000.

YORK HAVEN—The Conewago Felt & Paper Co., recently organized with a capital of $300,000, is perfecting plans for the erection of the initial unit of its proposed new local plant, to be 1-story, 35x170 ft. A site has been selected. Hamme & Witman, City Bank Bldg., York, Pa., are architects. E. E. Brunner, president of the York Haven State Bank, is head of the new company.

OIL CITY—The Penn-American Refining Co. has work under way on extensions at its local gasoline refinery, for considerable increased output. A 3-unit cracking plant will be installed.

South Carolina

COLUMBIA—The Southern Silica Mining & Mfg. Co., 1643 Main St., is planning for the installation of additional mechanical sand drying equipment at its plant with capacity of about 150 tons per day. Inquiries are out for the apparatus.

Tennessee

RICHARD CITY—The Dixie Portland Cement Co., Chattanooga, has tentative plans under consideration for extensions and improvements in its local cement manufacturing plant, estimated to cost about $175,000, including machinery.

Texas

BLOSSOM—The Blossom Oil & Cotton Co. is reported to be planning for the rebuilding of the portion of its local cotton oil mill, destroyed by fire, Jan. 18, with loss approximating $60,000. The reconstruction is estimated to cost a like amount. Additional equipment will be installed.

HOUSTON—The Magnolia Paper Co. has plans in progress for the erection of an addition to its local paper mill, estimated to cost approximately $75,000.

ROTAN—J. W. Patton, operating a local lime plant, has disposed of a portion of his property to the Universal Gypsum Co., which plans for the early erection of a new plant for the manufacture of cement, wallboard and other gypsum products. It is estimated to cost close to $75,000, with machinery, and will give employment to about 125 men at the start. C. E. Williams is an official of the purchasing company.

Virginia

ROANOKE—The Cement Products Mfg. Corp., recently organized with a capital of $30,000, has plans in progress for the erection of a new plant on local site for the manufacture of cement products, including tile, shingles, blocks, etc. Ground will be broken at an early date. E. A. Buchanan, P. O. Box 1172, is secretary and general manager.

WINCHESTER—The National Fruit Product Co., manufacturer of vinegar and other apple byproducts, is planning for extensions in its plant to double the present output. A new tank department will be installed with total capacity of 2,500,000 gal. C. E. Koontz is manager.

PETERSBURG—The Dodge Leather Co. has tentative plans under consideration for the erection of an addition to its plant for considerable increase in capacity. L. F. Dodge is president.

SOMERSET—The Rapidan Soapstone Corp., Orange, Va., recently organized with a capital of $200,000, has plans under consideration for the erection of a new plant on property acquired in the vicinity of Somerset. Kesee Brooking is president, and D. N. Davidson secretary and treasurer.

PETERSBURG—The Capitol Oil Co., Union Trust Bldg., recently organized, will soon commence the erection of a new oil storage and distributing plant, estimated to cost about $40,000.

West Virginia

SOUTH CHARLESTON—The Westvaco Chemical Co., Charleston, is planning for the construction of an addition to its South Charleston works, to consist of a complete operating unit, estimated to cost close to $50,000. The structure will be used for the conversion of brine products into chemicals. F. J. Kaufman is general manager.

CHARLESTON—Foundations are under way for the erection of the proposed 1 story addition to the local plant of the Owens Bottle Co., to be 120x200 ft., estimated to cost approximately $150,000. Other additions will be made at a later date. Headquarters of the company are in the Nicholas Bldg., Toledo, O.; the Devore Co., same address, is engineer.

Wyoming

CLAYTON—The Sinclair Crude Oil Producing Co., affiliated with the Sinclair Consolidated Oil Corp., 45 Nassau St., New York, will commence the erection of a new local storage and distributing plant comprising thirty 80,000-bbl. capacity steel tanks and auxiliary equipment.

Industrial Developments

LEATHER—Dungan Hood & Co., Philadelphia, Pa., are running their tanneries at close to 75 per cent of normal.

The Premier Leather Co., Boston, Mass., has resumed the production of black and colored glazed kid at its Philadelphia, Pa., plant, and expects to gradually advance manufacture in this line.

Robert H. Foerderer, Inc., Philadelphia, Pa., specializing in the production of glazed kid, is operating at its Frankford tannery at about 75 per cent of capacity.

CERAMIC—The Western Brick Co., Danville, Ill., is maintaining capacity production at its plant giving employment to about 400 operatives. The wage scale has recently been advanced.

The Champion Spark Plug Co., Toledo, O., is now operating on a production basis of 120,000 spark plugs per working day, or on a schedule of 271 a minute. A full working force is being employed. The plant is said to be the largest in the world devoted to this line of manufacture.

The Mapelton Clay Products Co., Mapleton, O., specializing in the manufacture of face brick, is developing capacity operations and expects to be running on a basis of 45,000 bricks daily at an early date. This schedule will be maintained for an indefinite period.

The Birmingham Clay Products Co., Birmingham, Ala., manufacturer of brick, is running on a full-time schedule at its local plant, giving employment to the regular working force. The company has work under way for a new kiln room for general increase in capacity, and is also considering the erection of other plant additions.

The Southern Brick & Tile Co., Louisville Ky., is arranging for the early resumption of operations at its plant, recently closed down for necessary repairs. A close to normal working force will be employed.

The I. L. Stiles & Son Brick Co., North Haven, Conn., is operating on a basis of about 60,000 bricks per day at its local plant, and is installing additional mechanical drying equipment to provide for further output.

Terra cotta plants in the Chicago, Ill., district are operating at maximum capacity with full working forces. A number of the plants are booked with orders insuring the continuance of this schedule well into spring.

The Louisville Fire Brick Works, Louisville, Ky., is operating its local plant at approximately 65 per cent of normal capacity. The branch plant at Grahn, Ky., is maintaining approximately this same schedule.

The Alton Brick Co., Alton, Ill., is planning for the early resumption of operations at the plant of the Banner Clay Works, Edwardsville, Ill., recently acquired. A portion of the plant is being remodeled and improved, and additional equipment will be installed.

GLASS—The National Glass Co., Shreveport, La., manufacturer of window glass, has perfected plans for the immediate reopening of its plant, giving employment to about 250 operatives. The works have been closed for some time past.

The Owens Bottle Co., Toledo, O., is running on a capacity basis at all of its plants, and expects to continue on this basis for some time to come. Full working forces are being employed.

RUBBER—The Woonsocket Rubber Co., Woonsocket, R. I., a division of the United States Rubber Co., has announced a full-time working schedule, effective Feb. 1 until further notice; it is expected that this basis will be continued throughout the year. At the same time the company has advanced wages at the plant, as well as at the branch factory at Millville, Mass., affecting about 1,900 operatives.

The B. F. Goodrich Co., Akron, O., has acquired the plant of the Ames-Holden Tire Co., Kitchener, Ont., for increased production for Canadian trade. The plant has a rated capacity of 1,000 tires a day and will immediately be placed on this full-production basis for a full line of Goodrich tires. The company is maintaining full operations at its main works at Akron, O.

The Boston Rubber Shoe Co., Malden, Mass., a branch of the United States Rubber Co., has advanced the wages of employees at the local mill. Employment is now being given to close to 2,000 persons.

CEMENT—The Atlas Portland Cement Co. New York, is arranging for an early increase in production at its mills in different parts of the country, placing all plants on a full-capacity basis for the first time since 1914. The No. 3 plant at Northampton, Pa., has already adopted a maximum output schedule, with capacity of 10,000 bbl. per day. Other plants of the company are located at Hudson, N. Y., Hannibal, Mo.; Leeds, Ala.; and Coplay, Pa.

The majority of the cement mills in the Lehigh Valley district of Pennsylvania are running on a full turn, giving employment to regular working forces. This schedule will be maintained for an indefinite period.

Riggers at the plant of the Alpha Portland Cement Co., Martin's Creek, Pa., declared a strike, Jan. 22, when a demand for an advance in wages from 44 to 65 cents an hour was refused by the company. The men are still out.

IRON AND STEEL—The Algoma Steel Corp., Sault Ste. Marie, Ont., is arranging to resume operations at its local mills before the close of February. The plant has been closed down for some weeks past.

The Wickwire-Spencer Steel Corp., Buffalo, N. Y., is operating at capacity at all plants, with a day and night working schedule. The Worcester, Mass., mills are giving employment to 3,500 men and are declining immediate orders as the maximum production is not equal to the demand.

The Alan Wood Iron & Steel Co., Conshohocken, Pa., has advanced the working time at its Ivy Rock blooming mill from 5 to 6 days a week, with day and night operating forces.

The Temple blast furnace, Temple, Pa., now under new management, has repairs and improvements under way at the stack, and expects to blow in during March. The furnace has been idle for about 24 months past.

The American Sheet & Tin Plate Co., Pittsburgh, Pa., has advanced production at its Wheeling, W. Va., works, bringing the average production of the different plants to 90 per cent of capacity. It is said that labor shortage will not permit an increase over this schedule at the present time. All plants of the company are on the active list.

Steel mills in the Chicago, Ill., district continue to advance production and the leading plants are now running on a basis of 80 to 85 per cent of capacity, as compared with 75 to 80 per cent a month ago.

In accordance with its proposed schedule the Thomas Iron Co. has blown in its new blast furnace at Hokendaqua, Pa., with

rated capacity of 400 tons of pig iron daily The organization recently came under the control of the Reading Iron Co., of which L. E. Thomas is president.

MISCELLANEOUS—The American Cellulose & Chemical Mfg. Co., Ltd., Amcelle, Md, is perfecting arrangements for the early resumption of operations at its local plant, which has been closed for some time past

The Standard Oil Co of New Jersey has refused the demand of employees at its three refineries at Constable Hook, Bayonne Bayway and Eagle Works, Jersey City N J, for a wage increase. It is pointed out that the increase in average hourly earnings at the plants from 1914 to the present time has been approximately 190 per cent

Capital Increases, etc.

THE WHITEHEAD BROTHERS RUBBER CO Whitehead Rd, Trenton, N. J, manufacturer of mechanical rubber products, has filed notice of increase in capital from $60,000 to $180,000

THE PAN-AMERICAN PETROLEUM & TRANSPORT CO, 120 Broadway, New York operating oil refineries in Mexico, California and other locations, has arranged for an increase in capital from $150,000,000 to $230,000,000 for general expansion

THE MICHIGAN GREY IRON CASTINGS CO Harbough St, Detroit, Mich, has filed notice of increase in capital from $10,000 to $250,000 for proposed expansion

THE BROWN CO, Berlin, N. H, manufacturer of paper and sulphite products, is disposing of a bond issue of $2,500,000, a portion of the proceeds to be used for general operations, additions to working capital, etc

THE LAKE VIEW BRICK CO, 2758 Irving Park, Chicago, Ill, has arranged for an increase in capital from $50,000 to $200,000, a portion of the proceeds to be used for expansion and additions to working capital

GEORGE D WETHERILL & CO, INC, 113 Arch St, Philadelphia Pa, manufacturers of paints, white lead, etc., are arranging for an increase in capital from $500 000 to $3,000,000 for general expansion

THE DETROIT RUBBER PRODUCTS CO, INC, 565 East Jefferson St, Detroit, has filed notice of increase in capital from $50,000 to $125,000

THE BLOOMSBURY GRAPHITE CO, Bloomsbury N J, has arranged for an increase in capital from $50,000 to $100,000

THE KALAMAZOO SANITARY MFG CO Kalamazoo, Mich, manufacturer of sanitary earthenware products, has filed notice of increase in capital from $350 000 to $700 000

New Companies

THE BEETLE-BAKER CO, Lynn, Mass, has been incorporated with a capital of $10 000, to manufacture liquid rubber cement waxes, etc Lorenz F Muther is president and William L Newton, 362 Massachusetts Ave Boston, treasurer

THE HOOSIER RENDERING CO Kentland Ind, has been incorporated with a capital of $25,000, to manufacture fertilizer products The incorporators are Egbert S Hess, Rufus Robinson and Samuel L Barnhard, all of Kentland

THE NITRO CHEMICAL PRODUCTS CORP, New York, N. Y, care of J M Kram, 51 Chambers St, New York, representative, has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts The incorporators are C. Leventhal, N Gray and B Sustrain

THE GENERAL SMELTING & REFINING CO, Detroit, Mich has been incorporated with a capital of $10,000, to operate a metal smelting and refining plant The incorporators are Daniel Temchin and Samuel Cooper, 678 Leland Ave, Detroit

THE HUDSON FIREPROOF BLOCK CO, North Bergen, N J, has been incorporated with a capital of $300,000, to manufacture burned clay building blocks and kindred ceramic products The incorporators are John E Toolam, David T Wilentz and Leon E McElroy, Garden St., North Bergen

THE GENERAL PETROLEUM CO, 208 South La Salle St., Chicago, Ill, has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Frank Tillotson, I N Walker and O. E. Edfast

THE PEACE CHEMICAL CO., Phillipi, W Va., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are H. B. Grant, Sherman Lindsey and B. E. Snyder, all of Phillipi

THE UNITED PROTECTIVE COATINGS CORP., New York, N. Y, care of J. J Finn, attorney, Yonkers, N. Y, representative, has been incorporated with a capital of $50,000, to manufacture paints and special coatings The incorporators are C R Douglas and M F Cole

THE BENTON HARBOR CHEMICAL CO, Benton Harbor Mich, has been incorporated with a capital of $10 000, to manufacture chemicals and special chemical preparations The incorporators are Walter S. Burgess, H J Dunleavy and A L Hogue, all of Benton Harbor

THE ENTERPRISE LIME & BALLAST CO, 11 Green St, Cumberland, Md, has been incorporated with a capital of $100,000, to manufacture lime and affiliated products The incorporators are Charles E Schadt, William M Somerville and Harry R Donnelly

THE BERGER LEVY CO, New York, N Y, care of Bloomberg & Bloomberg, 1482 Broadway, New York, representatives, has been incorporated with a capital of $100,000, to manufacture glassware specialties The incorporators are H A and E N Bloomberg and W Kaufman

THE APEX SMELTING CO 180 North Market St, Chicago, Ill, has been incorporated with a capital of $60,000 to operate a metal smelting plant The incorporators are William Helfand, Samuel Berenbaum and Sidney E Levy

THE SHELBY IRON & CHEMICAL CO, Memphis, Tenn, care of the Delaware Registration Trust Co, 900 Market St, Wilmington Del, representative, has been incorporated under Delaware laws with capital of $1,000,000 to operate iron properties, byproduct chemical works, etc The incorporators are M N Harris H W Dow and C D Shelow, Memphis

THE FRENCH MICA CO, 208 Broad St, Elizabeth, N J, has been incorporated with a capital of $10 000, to manufacture mica products The incorporators are Russell W Leary, Malcolm W Clephane and Donald McL Somers

THE SERVICE GLASS CO, Detroit, Mich, has been incorporated with a capital of $10,000, to manufacture glass products The incorporators are E F Kellum, Roland H Newton and George W Clay, 2019 Poplar St

THE VITROLITE PRODUCTS CO, Buffalo, N Y care of Kent, Cummings & Means Dun Bldg, Buffalo, representative, has been incorporated with a capital of $55 000, to manufacture composition materials for table tops, etc The incorporators are F E Beluche, C DeF Cummings and G A Brenner

THE HOFFMAN BROTHERS TANNING CO, 1701 Grand Ave, Chicago, Ill, has been incorporated with a capital of $250,000, to operate a leather tanning plant The incorporators are Olaf C and Anton R Hoffman and Carl Peterson

THE PITTSBURGH LEATHER & GLUE CO. Pittsburgh, Pa., care of W F Stadtlander, 115 Frick Bldg, Pittsburgh, representative, is being organized under state laws to manufacture glue and adhesives, leather products, etc

THE PACIFIC BRICK & TILE CO., 5233 Alhambra Ave Los Angeles, Cal, has filed notice of organization to manufacture brick, tile and affiliated burned clay products The company is headed by Carl B Gallasch and Claude S Kerrick

THE DIXIE DISINFECTING CO, Dallas, Tex, has been incorporated with a capital of $10 000, to manufacture chemical disinfectants etc. The incorporators are E J and O S Boyd and S P. Solomonson, all of Dallas

THE CHEROKEE BRICK CO, Knoxville, Tenn, care of the Delaware Corporation Co Ford Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $250,000, to manufacture burned clay products, including brick, tile, etc The incorporators are R G and J C. Wright, and C. E. Campbell, Jr, all of Knoxville

THE HANNIGAN WATERPROOFING & MFG. CO, New York, N. Y, has been incorporated with a capital of $50,000, to manufacture waterpoofing compounds, paints, etc The incorporators are C R Buell, E Kazemier and T. P Hannigan, 51 Chambers St, New York. The last noted represents the company.

THE REGISTER OIL CORP care of the Delaware Registration Trust Co., 900 Market St, Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $100,000, to manufacture petroleum products

THE ADENZIT CO., Long Island City, N. Y., care of J. K. Gillette, 424 Steinway Ave., Long Island City, representative, has been incorporated with a capital of $15,000, to manufacture chemicals and chemical compounds The incorporators are T Moore, W. C. and I W Kober

THE R A MOORE LEATHER CO., Greenville, Tex, has been incorporated under state laws to manufacture leather products The incorporators are R A Moore, J. M. Massey and W N Miller, all of Greenville

THE ALUMINUM FOUNDRY CO, Boston Mass, has been incorporated with a capital of $10,000, to manufacture aluminum, bronze and other metal castings Harry D Finberg is president and Abraham Sherman, 138 Gaston St, Roxbury, Mass, treasurer

THE PETERS PETROLEUM CORP, care of the Corporation Service Co, Equitable Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with capital of $1 000,000, to manufacture petroleum products

THE LAKESIDE OIL REFINING CO, care of the Corporation Trust Co of America, du Pont Bldg, Wilmington, Del, representative, has been incorporated under Delaware laws with a capital of $5,517,500 to manufacture refined petroleum products

THE SOBRITE CHEMICAL CO, 236 7th St, Jersey City, N J, has filed notice of organization to manufacture polishes, etc G L Shoemaker heads the company

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its annual convention in Norfolk, Va May 7 to 9

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa, Feb. 12 to 17, 1923

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5 1923, at the Commodore Hotel, New York.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold a meeting in Cleveland, O, April 28 to May 1

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb 19, 1923

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its twentieth annual convention at the Greenbrier, White Sulphur Springs, W Va, June 7, 8 and 9

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb 8 and 9, 1923

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-sixth annual meeting at the Chalfonte-Haddon Hall Hotel, Atlantic City, beginning Monday, June 25, 1923, and ending either Friday or Saturday of that week.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL has postponed its annual conference from April 25, 26 and 27, to May 2, 3 and 4 It will be held in New Orleans, La

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St, Newark, N. J, the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923 The major subject will be "Management Problems of the Smaller Plants."

A PAPER INDUSTRIES EXPOSITION will be held in Grand Central Palace New York City, during the week of April 9, 1923, by the International Exposition Co.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting May 4—American Chemical Society, regular meeting May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

The Real Need for Aggressive Leadership

RECENTLY we have had some clear thinking and straight talking about international relations and this country's responsibility in the present European situation. It is especially significant that it is the voice of American business that is most insistent in its demand that our government should no longer seek to avoid its moral obligations to the rest of the world.

One of the most recent names to be added to the growing list of American business men who have protested our ineffective foreign policy is that of A. C. BEDFORD, chairman of the board of the Standard Oil Co. of New Jersey. Not long ago in the course of an address before the Merchants' Association in New York he laid the blame for our vacillating course squarely at the door of the "partisan political controversies which have driven us as a people into a position with reference to the rest of the world that is contrary to the sentiments and traditions of our country."

The real need of the moment is for aggressive leadership, and there are few that will disagree with Mr. BEDFORD that this must come from Washington.

> We are entitled to look to our government for leadership and guidance in this great crisis. We feel that it is of utmost importance that matters of such supreme and transcendent consequence should be considered by the American people and the American Government from the American standpoint and without regard to partisan political considerations.
>
> We business men appreciate fully all the difficulties which confront the administration, but we feel that we can unhesitatingly assure our government at Washington that the most aggressive leadership will be welcomed by the whole American people and supported by the irresistible forces of intelligent public opinion.

If such leaders cannot come from among those in our government who have guided our foreign policies in the past, it is not unreasonable to believe that organized American business will unofficially, but none the less effectively, assert itself in the interest of peace and order in Europe. In fact had not the last Paris Conference of Allied Premiers already been called for Jan. 2, it is not at all unlikely that American business through the agency of the Chamber of Commerce of the United States might have taken a hand in an effort to straighten out the reparations tangle. On Dec. 25, 1922, the German Industrie- und Handelstag, the leading commercial body of Germany, invited the Chamber of Commerce of the United States to appoint a commission to investigate and express American opinion on the subject of German reparations. This evidence of confidence on the part of the leading commercial body of Germany in a similar organization in this country was sympathetically received, and the invitation probably would have been accepted but for the fact that it was considered proper to suspend decision pending a possible settlement at the Paris conference. Events following the failure of the diplomats to reach an agreement moved with such swiftness and in such unexpected directions that hope of further action by the Chamber of Commerce of the United States is now rather remote. The incident is noteworthy, however, as indicating sentiment on both sides of the ocean that the time is not far distant when the business man will be asked to take a more active part in solving the political as well as the purely business problems of international relations.

Education Of the Intuitions

IN THE current issue of *Engineering Education*, the president of Antioch College, ARTHUR E. MORGAN, declares that the chief defect in technical education today is the failure to educate the intuitions. By intuitions he means the ideas that seem to spring into being spontaneously and do not come as the result of conscious reasoning. Mr. MORGAN begins by acknowledging the debt that education and our modern engineering world owe to conscious reasoning and scientific analysis—a debt that is monumental and undisputed. But he points out that these rationalistic activities, which have built up the astonishing materialistic civilization that we now enjoy, are but tools by which intuitive purposes are accomplished.

All of us, he asserts, including engineers, live in the main by intuition. When we choose a wife, select a home, make friends or vote as a citizen, our intuitions generally control us. Yet the technical schools give students the impression that professional life is largely a succession of analytical processes. "As a matter of fact, in the professional work of most engineers who have gone beyond the stage of routine computers, decisions which must be arrived at by intuition both outnumber and outweigh those which can be reached by a purely technical approach."

President MORGAN continues: "Intuitions are not vagrants, arriving from nowhere and without cause or parentage. Rather they are normal and natural offspring, to some extent of heredity, but in very great measure of education and environment. . . . To the extent that the student's attention at college is confined to a consideration of technical principles and processes, his intuitions, outside of these phases which technical training specifically develops, will remain narrow, instinctive, primitive and crude, and made up of comparatively few factors."

Intuition is an important source of knowledge, a source too often overlooked. It is true, as President MORGAN declares, that most of us make important decisions by use of intuition. We decide by its aid whether

or not to accept offers and opportunities, whether a new acquaintance is worth trusting or not, and what personal policy to pursue. EMERSON pointed out that most of our mistakes come from not following our intuitions, and that life's most difficult problem is in deciding in what proportions to mix intuition and rationalism. He personally advocated more intuition and less rationalism. The distinguished French philosopher BERGSON has taught similar principles.

Without doubt the ancient and medieval wise men trusted intuition too much and rationalism too little. But perhaps in our reaction away from mysticism and *a priori* judgments we have emphasized rationalism at the expense of intuition. We are even apt to belittle or forget the fact that many great contributions to science probably came from *a priori* ideas. Such a hard-headed and mathematical-minded scientist as JOHN DALTON is said to have got his great idea on the atomic theory more by intuition than rationalism. That is, he got the idea before he made the experiments; as a laboratorian he was what we should call a "sloppy chemist." How many of the great discoveries and inventions in science have probably come by flashes of insight (intuition) rather than by cold reasoning! Yet to hear many college lecturers expound their scientific methodologies, a student would be led to think that there is no such thing as intuition, and that professional life is entirely applied rationalism.

Should we not then admit the importance of intuition, and see that teachers of engineering are broad minded and philosophical enough to develop its use? President MORGAN suggests that this should be done by mixing cultural and technical teaching, not by keeping them in watertight compartments. The great need is for professors of engineering who are at the same time cultured and philosophical men of the world.

An Immigration Policy In the Making

NOT long ago the National Association of Manufacturers decided it was time to answer the question: What shall we do about immigration? The opinions of representative industrial leaders, farmers, bankers and economists were sought and their replies furnished the basis of an interesting discussion in the current number of the association's magazine, *American Industries*. As might have been expected, there was a unanimity of opinion that the present quota law is wholly unsatisfactory. But the symposium also brought out sufficient constructive criticism to form the basis for a sound and permanent immigration policy.

All of the replies to the association's inquiry have been summarized in a number of recommendations which will be found on page 327 of this issue. Among these are the proposals that the quotas should refer to the net immigration from any particular country and that in case of labor shortages in this country the Secretary of Labor should be authorized to bring about the admission of desirable immigrants. It is further recommended that registration, distribution and education of the incomers should be handled by a centralized bureau or commission with the idea that these processes could thus be carried out more expeditiously and at the same time in a more humane way. It was almost unanimously agreed that the literacy test should be abandoned and that in its place we should have a scientific selection of our prospective citizens made by American officials on the other side of the ocean.

It is gratifying to learn that the effect of these recommendations has already been felt and that some of them probably will be incorporated in a measure soon to come up for Congressional consideration. Members of the House Immigration Committee have agreed among themselves on several basic principles that will underlie any revision of the present immigration law. Although these plans would call for a 2 per cent quota based on the number of foreign nationals residing in this country in 1890 (instead of 3 per cent in 1910 as at present), it is claimed that such a law would be so liberalized as to make it possible to bring in 200,000 more aliens than are now admitted. This would be accomplished by broadening the executive powers of the Secretary of Labor and increasing the number of exemptions to the present quota classifications.

It is apparent that the change from the 1910 to the 1890 basis would have the effect of sharply reducing the quotas allotted to Italy, Greece and southeastern Europe, without materially affecting those of the northern European countries that in the past have furnished us with a more desirable type of immigrant. Certain features of the proposed bill, however, will require further classification and perhaps will have to be modified considerably. For example, the flexible provision authorizing the Secretary of Labor to extend quotas when necessary is now so worded as to apply only to skilled labor and accordingly would not be effective in relieving shortages of common labor such as are currently reported in the steel industry.

This much, however, can be said in favor of both the association's proposals and the committee's tentative bill: They mark the first step toward establishing a definite immigration policy for the United States. If this policy is to be a lasting one, it must be designed to serve the economic and social interests of the country as a whole—without giving favor to either manufacturing or laboring classes.

Twelve Months' Armistice In the Coal Industry

THE coal stock report just issued by the Department of Commerce and U. S. Geological Survey shows an encouraging increase in the supplies of bituminous coal on hand the first of January, as compared with the stocks 2 months before. Despite large winter demands and active business conditions, the supply has evidently slightly exceeded the consumption so that 36,000,000 tons is now on hand in the commercial stocks of the country. This is a sufficient excess above the minimum safe stock, approximately 20,000,000 tons, so that there need be no fear of serious coal shortage this winter.

It has recently been announced also that wage agreements between mine operators and bituminous coal miners will be perfected for the coal year beginning April 1. Thus the industry declares another 12-month armistice in the wage wars which have threatened to wreck not only that industry but all of the rest of American business. In the meantime, the coal "fact-finding" commission will have completed its studies and reported to Congress on the remedies for the persistent and recurring troubles incident to coal shortages.

It has been many months since industry has been able to look forward as comfortably to as regular fuel supply as is now assured for the next year. Within that year it is certainly to be hoped that a permanent solution will be found of the problems of this basic industry.

What Makes a Good Journal Bearing?

IT MIGHT be assumed that the problems connected with bearings and bearing metals have been solved. On the one hand, mechanical engineers have constructed roller and ball bearings, assembled with a watchmaker's precision, or installed very effective systems of forced lubrication for the older types of journal bearings. Metallurgical problems might also be thought to have vanished, since specifications and foundry practice on babbitt, railroad "brasses" and bearing bronzes have been little changed for years. However, new metallurgical problems are continually cropping up and are being given careful consideration. To cite only three: How far can hardness in a bearing race be sacrificed to machinability? What is the best bearing metal for alloy-steel shafts in high-speed automobile or airplane engines? What kind of metal should aluminum castings or forgings rub against?

Theoretically, the load on a journal should be borne by an oil-film. Practice sometimes falls far short of this ideal, but all the progress that has been made in the mechanical and metallurgical construction of bearings has been effected by providing this minutely thin film more perfectly and more continuously. In view of its tremendous importance, we might pause to ask, Who is pressing a systematic, scientific research on the physical and chemical properties of lubricants? But that inquiry would lead us far afield, so for the present let us consider the effect of those undoubted metallurgical factors which come into play when the oil film is temporarily broken—chiefly when the shaft is starting or stopping its motion.

Experience had developed several highly successful bearing alloys long before modern metallography showed us that each was comprised of an aggregate of dissimilar crystals having a marked difference in hardness, plasticity and resistance to wear. The hard ones support the journal when metallic contact exists, and at such times they must be hard enough to support the load and yet not hard enough to score the shaft. The softer constituents wear away slightly faster and leave pocks for the lubricant. They always contain a minute amount of oil, but a quantity so necessary to prevent seizing during those critical periods when the journal is just starting or when enduring a momentary overload. It has also been found that successful bearings of long life almost invariably polish the journal during "running-in," and in turn the journal polishes the bearing. Now, bearing in mind that diamond dust will polish diamond, but no matter how worn it is, it will not polish emerald, it is apparent that the hardest constituent of the bearing must be of the same order of hardness as the journal which runs in it. Of course if a journal were glass hard and were mechanically and geometrically perfect it would run in any true bearing, but imperfections in alignment and finish are always greater than the thickness of the oil films; consequently in practice incipient wiping and polishing of one on the other always results. Sometimes the harder crystals in a bearing actually fuse on their surface to an observable extent during the preliminary "running-in."

For several years past a research committee of the American Society of Mechanical Engineers has been considering problems allied to the main question, "What makes an excellent bearing?" Early in their investigations they concluded that the literature was so contradictory it could not possibly be harmonized. Furthermore, they were of the opinion that experience furnished the only criterion of a successful bearing. If a number of satisfactory combinations of bearing and journal (and some unsuccessful ones as well) could be collected, the next step would be to study the hardness, orientation, melting point and relative amount of the various microconstituents of both pieces. In other words, the utmost resources of modern metallography must be brought to bear on the problem in order to duplicate the successful combinations unerringly, and as certainly avoid the failures.

The first steps have been brilliantly successful. They have devised a beautiful instrument of precision (called by the ugly word "micro-character"), whereby a jewel point, 1,000 times sharper than the finest cambric needle, is drawn across a polished surface, ploughing a tiny groove in the crystals of the alloy of a width depending upon the hardness of each constituent. Its use has already cleared up several puzzling anomalies. Tin oxide crystals more than twice as hard as martensite have been found in poorly cast, oxidized bronzes—evidently such a bearing would score any journal. One babbitt analysis (Sn 90, Cu 10 per cent) contains crystals of $SnCu_4$ harder than cold-drawn shafting of low-carbon steel, and contrary to the theory of babbitting and the general impression among engineers harder than anything yet found in bronze. Nevertheless, that is the reason this particular babbitt is most unsatisfactory with soft steel journals.

However, the problem has outgrown the resources of the committee. It will be necessary, therefore, if the work is to continue, to put a competent investigator at work in some institution like the Bureau of Standards studying the intimate metallurgical details of many tried and true bearings now existing. In view of the importance of accurate knowledge about bearings to railroads, machine tool builders, engine and pump manufacturers, the automotive trade and the makers of bearing metals, the necessary funds will doubtless be forthcoming without extensive solicitation. Enlightened selfishness demands that the metallurgists in these industries get behind the most excellent program proposed by the Mechanical Engineers' committee—the results of the study will return their cost over and over again, like perpetual compound interest. Many a "hot box" has cost more than the expense of the research for a month.

A Protest From Germany

THERE has come to our desk a 28-page pamphlet containing a reprint of articles recently appearing in the *Chemiker-Zeitung*, by Dr. W. A. DYES of Berlin, relative to Mr. NEGRU'S articles on conditions in Europe. It is a protest against almost everything that Mr. NEGRU has said about Germany. The author marshals no fewer than ninety-seven references to other authors or publications whose expressions regarding Germany evidently please him better than did those appearing in this magazine. It is another example of the unwillingness or inability of the German mind to admit that Germany did anything during the years 1914-1918 to lose the confidence and respect of the other civilized nations of the world, or that in her evasion of the terms of the treaty of Versailles and the general conduct of her economic affairs in the past 4 or 5 years she has immeasurably delayed a return to world-wide peace and prosperity. The editor of *Chemical Age*, London, has appraised the value of Dr. DYES' pamphlet so fairly that we publish his comment elsewhere in this issue.

Readers' Views and Comments

Costs of Producing Natural-Gas Gasoline

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have carefully looked over the costs of producing natural-gas gasoline as given in the manuscript you kindly sent for my inspection[1] and I believe that the figures are approximately correct. However, I should change the cost of construction of a high-pressure absorption plant with a capacity of 10,000 gal. per day from the figure Mr. Sievers uses—namely, $450,000 or $500,000—to $200,000 to $300,000. Also I should change the cost of a charcoal plant of 4,000 gal. a day capacity from $90,000 to $125,000. I happen to be building one of about this size at the present moment, and I think this latter figure is more nearly correct.

The reason I am suggesting that the 10,000 gal. per day absorption plant be reduced is that I am familiar with some very recent developments whereby it is claimed a 6,000-gal. oil-absorption plant can be built for only $100,000. This plant embraces some new improvements, and while I am a little skeptical about the figure, yet it is probably not far from the actual cost.

It might be pointed out that while the cost of operation of the compression plant showed 11c. per gallon, this includes a very large sales cost, whereas apparently the absorption plant cost of 6½c. per gallon, which Mr. Sievers mentions, does not include sales. At the present moment the production at the compression plant he cites is about 5,200 gal. a day, and the costs have been reduced through various economies and larger gallonage to about 8½c. a gallon.

Pittsburgh, Pa GEORGE A. BURRELL, Petroleum Engineer

What Is Steel?

To the Editor of Chemical & Metallurgical Engineering

SIR:—In my opinion this question—What is steel?—has been treated in a most masterly way by the late Dr. H. M. Howe in the chapter on Classification and Nomenclature of his book, "The Metallography of Steel and Cast Iron," in which he shows that historically and logically we seem to be forced to use a classification based on origin; and, according to the practice generally used in all but the Teutonic countries, the present industrial classification is satisfactory and sufficient except for blister steel and ingot iron. In accord with this system is Dr. Matthews' definition of steel: "Steel of commerce is that form of iron which has been produced by melting to yield a finished product which is malleable."

Dr. Howe considered a structural classification not practical; nevertheless, if it be considered desirable to distinguish between low-carbon steel and ingot iron, which difference Dr. Matthews' definition ignores, this may be done metallographically, since it so happens that cementite appears to be soluble in ferrite over the carbon range embraced by ingot iron. Thus, up to a content of 0.03 per cent carbon, according to H. Scott (*Chem. & Met.*, Dec. 13, 1922), its existence is not detected by thermal or microscopic means, or A_1 is absent in ingot iron and of course also in electrolytic iron and in much wrought iron. The other elements, manganese, sulphur, silicon, etc., which may also be present, need not be considered in the definition, since they may be classed as constituents of, or impurities in, either iron or steel.

On the high-carbon side, there does not appear to be as sharp a demarcation between steel and cast iron, for example, as appears to exist between ingot iron and steel.

Your proposed definition, "Steel is a malleable alloy of iron and iron carbide," may be ambiguous with respect to wrought iron.

Recognizing the disappearing product known as blister steel as an anomaly, Dr. Matthews' definition may be modified to eliminate ingot iron: "Steel of commerce is that form of iron which has been produced by melting to yield a malleable, finished product in which iron carbide can be detected." GEORGE K. BURGESS,

Bureau of Standards, Washington, D. C. Chief, Division of Metallurgy.

Problems in the Production of Sodium Sulphide

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the editorial on "Sodium Sulphide" in your issue of Jan. 10, this company has produced sodium sulphide both by the direct method and as a byproduct from the barium industry. While we believe the barium industry is permanent in this country, still you are correct in saying the sodium sulphide derived therefrom cannot be regarded as a basic source, because at the very best it is variable. Regarding the direct method, what you say is very true indeed. It is our belief that any great improvement in the direct process must of necessity get away altogether from either reverberatory or rotary furnaces. However, experiments along this line we think should be confined solely to the amount anyone can afford to lose on a venture. JAMES B. PIERCE, JR.

Rollin Chemical Corporation, South Charleston, W. Va

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have noted with interest your editorial in the Jan. 10 issue regarding the manufacture of sodium sulphide. This problem is indeed an intricate one and one to which manufacturers have given serious thought. A process with a low per cent yield of the soda input is one which offers a big chance of improvement and, at the same time, the rough semi-skilled labor necessary, which continually grows harder to obtain, also makes improvement necessary.

Seemingly all attempts at improvement have met with only meager success, both in this country and abroad. Careful temperature control would aid greatly, but to simplify this for operation by the class of labor necessary presents a difficult problem in that no suitable recording instrument has yet been found which stands up under the furnace conditions. Again, impurities entering the crude product from the furnace walls, etc.,

[1]This article by E. G. Sievers appears on pp. 297-8 of this issue of Chem. & Met.

tend to make filtration of the solution of dissolved sulphide melt impossible, and here again a difficult problem is met.

The production of a fluid melt which could be run directly from the furnace into water, forming an immediate solution, would cut down subsequent crushing and handling costs, but to obtain proper fluidity, the amount of the reducing medium, such as coal screenings, has to be lessened to such an extent that proper reduction does not take place and again one is baffled. Finally, a large stack loss is also entailed in the present process which presents a problem where a saving could be made.

It is believed, however, that in time these problems will be solved as this one of the crudest processes in the inorganic chemical industry must of necessity be eventually improved.

Further comments on your editorial will be interesting.

ARTHUR L. GARDNER.

Merrimac Chemical Co.,
Everett, Mass.

Long-Term Credits and The Fertilizer Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial in the Jan. 10 issue, entitled "Long-Term Credits and the Fertilizer Industry," the facts as you state them are essentially correct, but the conclusion at which you arrive is not a practical possibility, if for no other reason than that it undoubtedly would be held to be an agreement in restraint of trade.

CHARLES H. MACDOWELL,
President, Armour Fertilizer Co.

Chicago, Ill.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I read your recent editorial entitled "Long-Term Credits and the Fertilizer Industry" with a good deal of interest. You are quite right in saying that long-term credits is one of the very serious problems of the industry, and you could safely have added that it is also one of the most pernicious practices. However, I hardly think this practice was started with a view of increasing the tonnage already established, but on the other hand I think it was more to induce the use of fertilizer where it had not been used before. Now that its use has passed the experimental stage, it seems to me high time for the industry to change its selling policy.

Years ago the average farmer looked on a sack of fertilizer as being nothing more than a bag of sand through which a polecat had been drawn, but since that time our agricultural colleges have established without question the value of fertilizer and have convinced the intelligent farmer it is as necessary for him to feed his plants as it is for him to feed his stock if he hopes to get best results.

You are right in saying that competition is one of the causes of long credits. Some fertilizer concerns, in their anxiety for tonnage, seem to have little if any regard for the credit risk involved, and apparently are willing to give almost any credit terms, merely to effect a sale, with the result that the fertilizer industry has really been playing the part of banker to the farmer. However, the industry is endeavoring to get away from this practice, with the hope of putting the business on a cash basis, as it should be.

Cottonseed meal is rarely, if ever, sold on other than cash against documents terms, even though it is used by the farmer as a fertilizer, and yet that same farmer, who would willingly pay cash for his meal, nitrate of soda and other fertilizer materials, balks when it comes to paying cash for his manufactured fertilizer.

Another bad feature about long-term credits is that a great many merchants were really averse to handling fertilizer, but did so in order to get the other business of the planter. However, to get this business they used the fertilizer as a leader and sold it at practically cost to them, thereby losing the interest on the money they advanced to pay the freight (where freight was not prepaid) and also receiving nothing for their trouble and expense in handling the goods. The result was, when their notes for this fertilizer became due, they figured that the fertilizer end of the business was the last thing to be paid, for the reason that they themselves made no profit out of it, which, of course, was a poor excuse.

Again, country merchants, who could not borrow money from a bank without putting up ample security, bought fertilizer on credit and sold it out at its exact cost for cash, which money they used in their business without interest from date of shipment until May 1 (the usual settling date). Then when they settled on May 1, they would give their notes due in the fall, said notes including interest from May 1 to maturity, without any security whatever. When these notes matured, the merchants seemed to feel that they were the last things to be paid, and in many instances it was with great difficulty that collection of them was effected.

In the southeast Atlantic states the custom has been to prepay freights on shipments of fertilizer. This means that the fertilizer manufacturers have not only extended credit on their goods, but they have loaned the country merchant the money (without interest) with which to pay the freight. The reason this pernicious practice was started was competition. However, it did not reach what is known as the Southwestern territory —that is, the Southern section west of the Mississippi River—until the last few years, when it was introduced by the packers at the time they entered this field.

The industry has made greater strides in the last 2 or 3 years toward putting the business on a cash basis than ever before, and banks throughout this territory are beginning to recognize the fact that they must assist in carrying the credit risk, and therefore a number of them are now beginning to make loans to farmers to enable them to buy fertilizer, and the fertilizer industry is helping this along by offering very attractive discounts this year.

E. K. HUEY.

American Cotton Oil Co.,
New Orleans, La.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your recent editorial, the manufacture of sodium sulphide still remains, so far as I am aware, just about where it was in Weldon's time. During the 25 years that I have been interested in it, the slight attempts that have been made toward improvement have left the process just about where it was. Mr. Gardner's letter to you enumerates some of the difficulties that have been met. The men who did much of the work many years ago are no longer with us. The results were negative and the details of the work done are lost. I am quite convinced that any real improvement in manufacture must be along lines radically different from any that have as yet come to my attention.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Jan. 18, 1923.

ALTHOUGH the political situation in Europe gives rise to anxiety, the general improvement that has taken place in the chemical trade during the last few months is still maintained and prices as well as business both for home and export account are increasing slowly but surely. It is perhaps premature to form any opinion as to the effect of the occupation of the Ruhr upon specific industries, but it is fairly clear that the coal and the iron and steel trades will improve, at any rate temporarily. The textile trades continue very firm and have helped to maintain stability in chemical markets. The prices of German fine chemicals will presumably advance in the near future, and it almost seems as if the British fine chemical industry, which, as previously noted in these columns, has been more or less moribund for a long time past, will experience something of a revival. There is also a distinct improvement in the sales of dyestuffs.

GOOD COAL AND OIL PROSPECTS

Cheap coal has always been a prime necessity for this country, but although the output is almost at its maximum, having regard to the 7-hour day, and pithead prices are only about 60 per cent above pre-war, freight and other expenses are up about 90 per cent. Pressure has been brought to bear upon the railways to reduce freights, but so far without success. Nevertheless, a reduction is confidently expected in the late spring and if it should also be possible to induce the miners to revert to the 8-hour day, that would make all the difference in enabling the heavy influx of orders to be filled and in giving the necessary impetus to the chemical and allied industries.

Fuel oil continues to gain favor and low-temperature carbonization of certain cannels and other low-grade coals is showing a progressive increase, probably because such installations do not depend upon the sale of smokeless solid fuel. Very substantial progress has been made in low-temperature retorting, and active developments are reported in the distillation of shales, torbanites, lignites and the like.

INDUSTRIAL AND TECHNICAL DEVELOPMENTS

The past year has not been very prolific as regards the introduction of new processes, and that may have to some extent been due to the natural reluctance of manufacturers in hard times to encourage expenditure on hypothetical schemes. The outlook and position is now changing and quite a number of promising developments are under way. Mention might be made of the tendency to import liquid rubber latex instead of crêpe and of two processes using latex, the one giving cold vulcanized products practically without odor and without brittleness in the cold, and the other enabling practically the whole of the constituents of the latex to be imported in solid or pasty instead of liquid form, thus saving freight yet enabling the essential parts of the latex to be reconstituted for manufacturing processes after arrival. As mentioned in last month's notes, the process for coagulation of blood and tankage by means of suitable reagents is now being tried out and phonograph records, cotton spinners' bobbins, waterproof paper, electrical goods and buttons may be instanced as probable applications. English patent 165,832 indicates that the blood is heated for about 24 hours at about 50 deg. C., preferably in a closed vessel, and the aëration is carried to such a point that coagulation to a stiff jelly can be effected in about 2 hours by adding 2 to 4 per cent of 40 per cent formaldehyde or ½ per cent of caustic soda. Alternatively the blood may be injected in a thin stream into hot water containing coagulating reagents, and it is stated that the cost of manufacturing material that would be suitable for molding purposes is about 3c. per pound. In referring to development and new inventions your correspondent has often been struck by the fact that business trips to Europe would be more profitable in every way if made in the spring instead of being combined with a vacation during the "rush" period. In the summer business topics are at a discount in spite of numerous "prospects" from America, and firms would do well to consider carefully planned winter or spring trips instead, preparing the ground beforehand by correspondence and representatives' reports.

GENERAL NEWS AND NOTES

The Society of Chemical Industry's new weekly journal *Chemistry and Industry* has, on the whole, been favorably and tolerantly received and is already showing signs of improvement. A not unexpected feature is the indirect advertising that the society has received by providing a general topic of conversation. The *Chemical Age* has now incorporated the monthly *China Clay Trade Review* and in view of the revival in this industry and its close connection with many chemical works, the moment seems opportune.

The public is taking considerable interest in the official inquiry as to charging for gas by its thermal value and a few recent accidents have produced much unjustifiable criticism of carbon monoxide content and its dangers. The tendency is still for a reduction in gas prices and for an increase in the declared calorific value.

E. V. Evans has resigned his appointment as a member of the Dyestuffs Advisory and Development Committees and his place has been taken by Mr. Dawson, manager of the British Alizarine Co., and Mr. Blundell, of the North British Chemical Co., Ltd., respectively. Dr. Carpenter has resigned from the Council of the A.B.C.M. (Association of British Chemical Manufacturers) and Dr. Clayton, M.P., succeeds him.

The death of Prof. George Lunge at Zurich is a reminder of the great debt which the chemical industries of all countries owe to this literary pioneer and inventor. It may be of interest to know that one of his sons is head of the development department of Courtaulds, Ltd.

The Institution of Chemical Engineers is now definitely in being and the first batch of members has already been elected by the Council. Reciprocal arrangements have been made with the American Institute of Chemical Engineers for attendance at meetings and in regard to proceedings; applications for membership already exceed two hundred.

Your correspondent regrets an unfortunate error in quoting prices for pitch in last month's notes. The price a few months ago should read $12.50 and the level in December was $28. As anticipated, prices have slightly increased since to $30.

Although the Wooden Barrel Was Invented Far Back Before the First Dawn of Written History, Little Is Known by the Average User as to the Proper Care to Give Them When Handling and Storing — Some Startling Figures Are Presented Showing the Money Involved

The Dollars and Cents Of Careful Barrel Handling

BY MATTHEW WILLIAM POTTS
Consulting Engineer, New York City

THERE is no doubt that the chemical and allied industries of this country are the greatest users of wooden barrels, and this includes what is known as tight and slack cooperage. I have been in plants where the plant managers and purchasing agents are not familiar with the meaning of the terms tight and slack cooperage, and yet they are using hundreds of barrels per day. This lack of knowledge goes right down through the organizations and is the cause of much abuse to the barrels, loss of materials through leakage, contamination of contents, etc., which amounts to thousands of dollars per year.

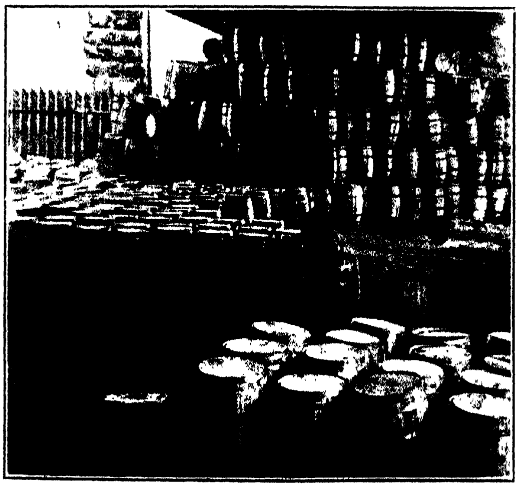

FIG. 1—EXAMPLE OF POOR EMPTY BARREL STORAGE

Recently a large chemical company contemplated the use of bilged steel barrels as shipping containers for its products. These barrels were to be billed to the customer with a refund, providing they were returned to the company.* This system is now in use by a number of large chemical industries, but it has nearly as many disadvantages as the old wooden barrels.

Upon investigation, the chemical company of which I speak found that most of its trouble was due to its own carelessness in the handling and storage of the wooden barrels, both before and after filling. After correcting a few of the most flagrant cases of barrel abuse it was found unnecessary to provide a returnable container system and in this way an investment of money amounting to over a hundred thousand dollars was saved.

In another plant it was found that by properly storing the wooden barrels, both before and after filling, a cheaper grade of barrel could be used. This change in grade made a saving of 45 cents per barrel. The company was using approximately 200 barrels per day, 300 days per year, so this small saving per barrel amounted to $27,000 per year in barrel costs alone. There were additional savings in labor costs for repairing and coopering, claims on carriers and delays to customers.

"BARRELS ARE NOT WELL MADE ANY MORE"

The common complaints against the wooden barrels of today are: the wood dries out, hoops fall off, heads break in, liquid contents leak out between the staves, at the bung and around the croze of the barrel. These complaints are summed up by plant managers and purchasing agents in the statement, "The barrels of today are not properly made."

Replacing heads, putting on new hoops, coopering and recoopering are expensive. Leakage of contents amounts to a loss of thousands of dollars every year to manufacturer and consumer alike, but why place all the blame against the barrel manufacturer? Experience proves that leaks are caused more frequently from abuse (many times unintentional) than from improper manufacture. Barrels are most frequently ruined at the users' plant while empty. Fig. 1 illustrates a very frequent example of barrel abuse.

In the first place the storage location is improper. It is under a viaduct where rain and snow can beat in from either side, and there is a continual circulation of air. Drip and drainage from the viaduct falls down on the heads of the barrels, causing them to swell. When the photograph was taken the sun was beating down on the barrels as shown to the left. They are

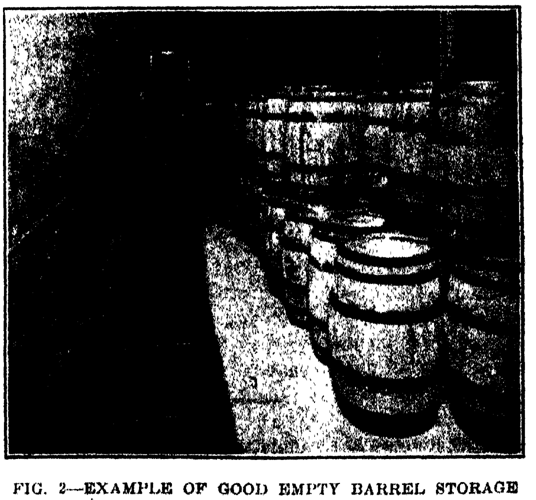

FIG. 2—EXAMPLE OF GOOD EMPTY BARREL STORAGE
Also shows barrels being handled by means of slat conveyors and gravity conveyors. (Courtesy Matthews Gravity Conveyor Co.)

FIG. 3—STEAMING THE BARRELS SO AS TO FORM THE BILGE
(Courtesy Cleveland Cooperage Co.)

practically unprotected and the alternating wetting and drying out of the wood has a disastrous effect. By looking closely, a number may be seen where the hoops have fallen off, one has only the two head hoops remaining. Considering that these barrels had been in storage only a week when the photograph was taken, they are in poor condition.

The Barrel Manufacturer Is Careful of Stock

To appreciate why a barrel should be protected it is helpful to give a little detail as to the method of manufacture. From the very start, great care is taken to remove just the right amount of moisture from the lumber. The rough staves are usually stored in the open for a year to season. Before they are ready to assemble into a barrel they are put into a hot room or dry kiln to evaporate the remaining moisture. To make the bilge, steaming is necessary, but this slight addition of moisture is later removed by firing. (See Figs. 3 and 4.)

This dryness of the barrel makes the staves and heads equivalent to blotting paper, with an affinity for moisture. This is the reason why the inside of the barrel is sized (or lined) if it is to be used as a container for liquids or pastes. If the absorption of moisture from the outside is not excessive, is constant and of an even temperature, the barrel will not be damaged. However, when moisture has been absorbed and subsequently evaporated, leaks will develop, because the swelling of the barrel has expanded the hoops and they do not return to their original diameter to hold the joints tight.

This is the reason it is necessary to store barrels in a proper location, under cover and in an even temperature. Extreme variations in temperature will open the joints. This trouble is experienced in March and April, when we have warm days and cold nights. This causes the staves and heads to expand during the high temperature in the day and there is no corresponding shrinkage of the hoops at night.

Fig. 2 illustrates a good empty storage and a good method of handling barrels. The features to note are the clean, dry, well-ventilated room where the barrels are kept, the even piles, the spacing so that the top ones are not resting on the heads of those beneath, but are resting on the chimbs with four points of contact and support. Also all hoops are tight and in proper place.

The handling of barrels is often considered of no importance because they are provided with a bilge which makes them easy to roll. This general practice or method is not recommended except where a track or runway is provided so that it is possible to get two points of contact near the quarter hoops. Fig. 2 shows an ideal way of handling barrels by means of an apron conveyor, or elevator, and gravity conveyors. Another means is by electric storage battery lift truck that transports the barrels from place to place and also elevates them for piling. The careless dropping of a barrel, if even for only 6 inches, is likely to break a stave, and to roll them on the bilge, allowing them to bump one another with force, has a tendency to spring the staves and produce leakers, especially if the barrels are packed with liquids or pastes.

Taking a little more care in barrel handling will be found a profitable investment. When unloading from trucks or automobiles the barrels should be lowered by means of skids. When being tiered they should be raised and lowered by means of portable elevators. When the barrels are to be transported for a long distance the track runway will be found very advantageous. This track or runway is simple in construction and consists of two strips of wood or small iron rails spaced approximately 18 in. apart. The writer has seen barrels filled with liquids rolled for a distance of a quarter of a mile and then turned at right angles to the first run

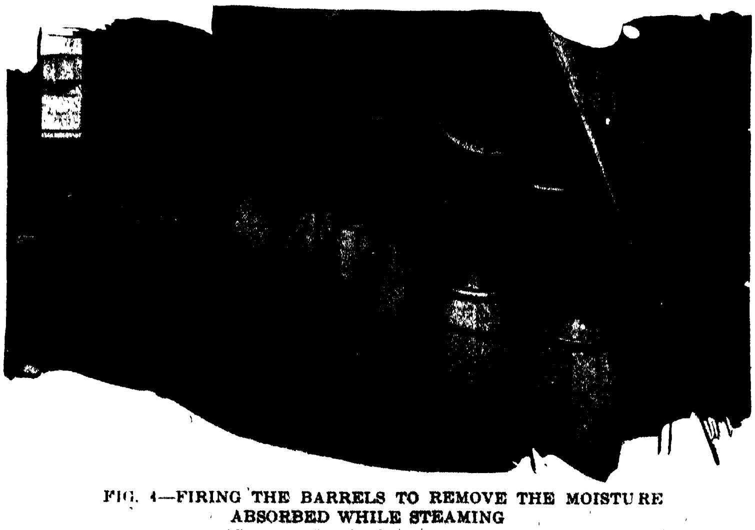

FIG. 4—FIRING THE BARRELS TO REMOVE THE MOISTURE ABSORBED WHILE STEAMING
(Courtesy Cleveland Cooperage Co.)

and rolled for an additional distance of over a thousand feet. In the entire length of this runway only two men were required to handle the barrels. One man was stationed at the right-angle turn and the other man patrolled the entire runway, so that when a congestion at any point made it necessary to stop the barrels he stopped them gently and did not permit them to bump together. In this way it was possible to load cars quickly and economically, as many as eight cars being loaded at a time.

The High Art of Coopering

Barrels are often ruined when they are being filled. They are almost always improperly coopered. These two points can be given very careful consideration. When barrels are to be filled with liquids, more care is required than if they are to be filled with a powdered or lump material. First the hoops should be driven tight. It is best to do this coopering by machinery as shown in Fig. 5, as barrel coopering is an art that few men understand and the machine coopering has been perfected to eliminate the human element. If, however, the number of barrels is small, hand coopering can be used and at all times the employing of an experienced cooper will be found economical, although it will be necessary to pay him more wages than an ordinary laborer.

For hand coopering and other purposes every barrel user should supply the cooper with the proper tools, which include a cooper's hammer, chimb maul and bung reamer. In addition, the cooper should have on hand at all times a supply of bungs, flag, pegs, extra heads and extra hoops. The hoops on a barrel should be tightened by light taps around the barrel and not by a hard blow at any one point. If the barrels are slippery, lump chalk should be used for better friction until hoops are in final position and fastened.

No matter what the product is, a barrel should never be completely filled. Ample room must be allowed for expansion. Some barrel users leave out a gallon in a 50-gal. barrel and smaller sizes proportionately. Others stop filling when the liquid is within 2 or 3 in. of the bung hole. Of course some liquids have a greater tendency to expand than others, which prevents giving a universal rule to follow, but care should be taken in this respect and the filler should adopt a safe, conservative policy covering this important point. Where barrels are filled by removing one head, as in the case of dry products, heavy pastes, etc., care must be exercised in replacing the head so that it fits square in the croze or groove. A leak in the croze (where head and staves come together) usually indicates a poor fit and can generally be stopped by hammering the outside of the barrel at that point until the head falls into place.

The final job of bunging up the barrel is often badly done. Putting in the bung is very simple, but it must be done right. First soak the bung in hot water so that it will expand quickly after it is driven in. Then insert it part way to make sure that it exactly fits the hole. If it is too tight, ream out the hole just a trifle with the proper tool. If it is too loose, wrap it with a piece of cloth, or preferably use a large bung. The final driving should not be done until the grain of the bung runs parallel with the grain of the stave (to avoid breakage), then hammer it "home" and turn the barrel to test for leakage. If it holds tight, seal the bung with a bung seal, or strap, and the job is properly done.

A number of chemicals are packed in the form of fine powder and it has been found that in order to save the leakage of content, no matter how well the barrel is made, it is necessary to remove one of the heads before filling and to insert a paraffine paper bag liner. The contents are then packed into this paper bag within the barrel, the top of the bag is drawn together and tied, the head replaced and the barrel is ready for painting and shipping. At this point there is overlooked an important help to the customer—namely, the marking of the head that has been removed so it will be possible for him to open the proper end of the barrel, so that when he has removed only a portion of its contents he can again tie the bag. This marking can easily be taken care of by having the cooper when he removes the head (before filling) nail a small embossed disk on the upper side. This disk can be about an inch in diameter and carry the words, "Open this end." Then when the head is replaced after the barrel has been filled there is no guessing as to which end to open.

After Filling and Before Shipping

Every barrel upon being filled, whether filled with liquids, lumps or powder, should have the hoops driven tight and nailed down with fasteners, or cleats, or dented into the wood with a sharp tool. This holds the hoops firmly in place against jolts and rough handling. Each hoop should have at least two nails or dents, one on each side of the barrel, and these should be placed only after the final driving of the hoops.

Painting of barrels is done for two reasons. First, to provide a protective coat for the wooden heads and staves, and second, to give a neat appearance to the package and to serve as an advertisement for the company whose products it contains. The painting and marking of barrels is according to the taste of each individual user. Some like blue barrels with white

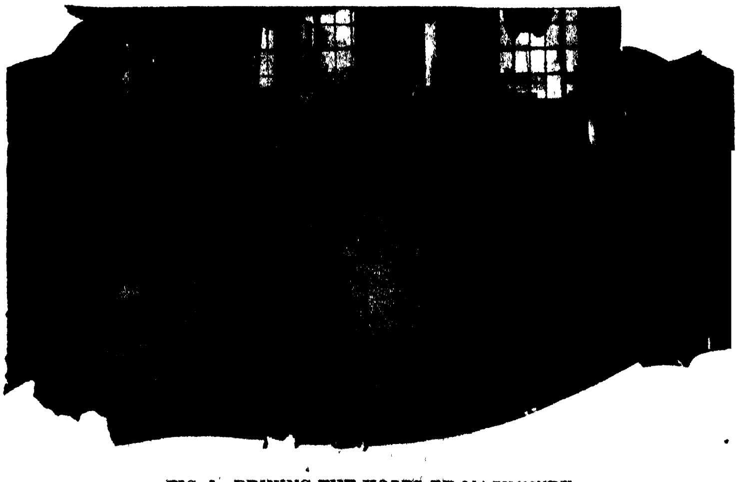

FIG. 5—DRIVING THE HOOPS BY MACHINERY
Note the number of grips on the hoops. This drives the hoops even and with just the right pressure.

heads, carrying a stenciled trade mark and the necessary shipping marks such as "Net, Tare and Gross" weights. Others like a red barrel with a white band around the center or bilge. The decorative effect is not so important as the proper time and method of painting. In a number of cases the barrels are painted before filling, but I believe the time to paint a barrel is just prior to shipment. The paint then acts as a protective coat, as it is fresh, and the slight addition of moisture swells the staves just enough to keep the hoops tight while in transit.

Machine Painting Often Economical

The method of painting depends upon the number being shipped per day. If this exceeds fifty, the use of machine equipment will be found economical. When the barrels are painted before filling, a revolving machine is the most advantageous, but when the barrels are filled and then painted, an air brush equipment with a revolving, lift turntable, will be found most satisfactory.

An investigation made by the writer gives the following comparison between the hand and machine methods of painting barrels as follows:

Data	Hand	Air Brush
Number of men on painting operation	2 or 3	1
Number of hours worked	9 to 12	9
Average man-hours per day	18	9
Wages per man hour	$0 45	$0 55
Average labor cost per day	$8 10	$4 95
Average number barrels possible to paint per day	175	175 plus
Cost for paint per month	$211	$110
Cost for brushes per month	18	0
Maintenance and operation per month	0	15
Depreciation per month using 15 per cent	0	$13 64
Total cost for 25 working days	$431 50	$262 39

Net savings due to air-brush methods $169 11 per month

Over and above the direct money savings is the speeding up of the work, a neater and cleaner painting space and general better working conditions.

The grade of paint to be used is also a matter of personal choice, but it must be remembered that your barrels in transit are a good source of advertisement and it is well to give them a good coat of paint and to use care in selecting distinctive colors. For ordinary commercial purposes, I would suggest either a paste, barrel paint, thinned with rosin oil or gloss oil, or a cheap dry earth paint mixed with rosin oil. The rosin oil can be purchased or can be made by pulverizing 3½ lb. "F" grade rosin and adding 1 gal. of naphtha. Apply heat, stirring until dissolved. This mixture should be kept in a covered receptable, as it evaporates quickly.

The common blue and white combination on staves and heads requires a paint mixture of 5 lb. dry paint with 1 gal. of rosin oil. If red or yellow is preferred, 3 lb. paint with 1 gal. of rosin oil. Raw naphtha should not be used for thinning, as it will make the surface dull or flat. When using the air-brush method of painting, the above specifications should be submitted to the manufacturer of the air-gun and should be approved by him before being used in the equipment.

The marking or tagging of barrels for identification is a problem on which many users have spent considerable time and money without obtaining satisfactory results. A covered envelope made of paper and tacked to the head or side of the barrel is generally used. These tear off in storage and in transit. If wetted, the writing blurs and the identification of the barrel is lost. The most satisfactory method of marking is to use an embossed metal tag. The barrel will then practically have to be destroyed before it will lose its marking.

Effect of Manganese on Steel

A method of preparing very pure iron has been developed at the Bureau of Standards and with this iron as a base various steels and other iron alloys have been made for the purpose of testing them without the complicating effect of impurities which are usually present in commercial iron and steel.

The use of manganese in steel as a strengthening agent in addition to the carbon is the chief subject of the investigation described in Scientific Paper 464 from the bureau, entitled "The Effect of Manganese on the Structure of Alloys in the Iron-Carbon System."

The use of higher percentages of manganese for producing high tensile properties in low- and medium-carbon steels has been recommended at times by various metallurgists, and to some extent such recommendations have been carried out in commercial practice. The results obtained in this investigation of the structural effects of manganese in steel strongly confirm such recommendations concerning this use of the element.

The general effect of manganese may be concisely described as a "restraining influence" so that the pearlite, even after annealing, exists in very fine-grained condition if considerable manganese is present. In this respect the steel resembles in structure and mechanical properties the condition which usually obtains in similar steels of low manganese content after rather rapid cooling—for example, air-cooling.

Manganese also appears to have a very noticeable effect upon the rate at which high-carbon steels, such as carbon tool steels and file steels, assume the granular or "spheroidized" state—a condition which for many purposes is very desirable. Manganese exerts its characteristic retarding influence upon this change.

Quarry Operators Should Apply Engineering Principles

"During recent years I have visited about 600 stone quarries," states Oliver Bowles, mineral technologist of the Bureau of Mines. "Many of these quarries are highly efficient operations, but on the other hand I find some processes in use that are as crude as those employed in Egypt when the pyramids were built. The employment of inefficient methods is due partly to lack of capital, partly to tradition or to the influence of methods used in surrounding operations, and partly to unusual quarry conditions, but one great outstanding lack is the failure to apply the principles of engineering to the problems encountered. Some problems may require the experience and knowledge of a trained engineer, and he should be called in consultation. In many instances, however, the operator is quite capable of solving his own problems by applying to them two important engineering principles. The first principle is the ability to see both sides of a question, to weigh the evidence impartially, and to dismiss from consideration any preconceived opinion as to the most desirable solution of the problem. The second important principle is the establisment of conclusions on a sound basis of fact. Thus the preparation of positive data is a necessary function of any investigator, and this can be done only by keeping exact records of tonnage and costs. Few economic problems can be solved without using figures, and no quarryman can hope to solve his problems without the aid of systematic records. Many processes now in use would be abandoned tomorrow if the operator had before him figures indicating their excessive cost."

Cost of Producing Natural-Gas Gasoline

The Scope of the Industry Is Briefly Outlined and Recovery Costs for Various Types of Plants Are Carefully Analyzed

BY E. G. SIEVERS
Washington, D. C.

FROM experimental production on a small and crude scale in 1900 to an output of 450,000,000 gal. in 1921 is the story, in brief, of the growth of the natural-gas gasoline industry in the United States. The first plant was constructed in Pennsylvania in 1904, but not until 1910 did the industry assume commercial importance. The production of natural-gas gasoline has made marked progress since 1915, due to the development at that time of the absorption process, which made it possible to remove the gasoline from dry gas and also to treat a much larger quantity of gas.

In 1911 the total output in the United States was 7,425,000 gal., but the annual production since then has increased rapidly. The output in 1921 was 596 per cent greater than that of 1911. Table I shows the production from 1916 to 1921 inclusive, and Table II shows the output in 1921 by states.

Gasoline is recovered from natural gas by two chief methods—namely, by compression and absorption. The compression method is applied to wet gas or that having a high gasoline content, whereas the absorption process is used for dry gas yielding less than 1 gal. of gasoline per thousand cubic feet of gas. Absorption plants are now largely replacing compression plants because the absorption product is more stable and demands a higher price. Present-day practice, however, has shown that the combination of compression and absorption plants is very successful, consequently many of the operators are combining these processes. About 75 per cent of the total annual output is produced at the compression plants.

One of the vital problems in the production of natural-gas gasoline is that of plant efficiency. Many plants are today operating under conditions not in conformity with good conservation practice. The producers, however, are mindful of this fact and are constantly working toward greater improvements. According to data compiled by the United States Geological Survey the yield of gasoline per thousand cubic feet of gas in 1921 was nearly 0.2 gal. greater than in 1920. In Table I it will be noted that there has been an annual increase in yield since 1916.

The economic importance of natural-gas gasoline is better appreciated when it is realized that it constitutes nearly one-tenth of all the gasoline produced annually in the United States. Natural-gas gasoline is highly volatile and therefore is blended with naphthas or refinery gasolines in preparation for the market. This is an economic factor in that the blending makes it possible to utilize large quantities of naphthas at the refineries otherwise having little commercial use. In view of the constantly increasing demand for motor fuels, the production of natural-gas gasoline must of necessity continue to be one of our essential industries.

Because of the rapid growth of the industry, due perhaps to the increasing demand for gasoline, not enough attention has been paid to the costs of construction and operation of plants. The greatest expansion of the industry came during the war when manufacturers were able to market their product at almost any price. Consequently there was little necessity for careful analyses of costs. The manufacturers were making good profits and, furthermore, were too busy solving mechanical problems to give more than cursory consideration to the matter of costs. The depression following the war demoralized prices, and made it difficult for the natural-gas gasoline manufacturer to locate a market. As a result there was greater scrutiny in business methods and costs, and at the present time every effort is being made to put the industry on a firm basis.

One of the first steps necessary was to combine

small unprofitable plants into fewer large plants. It is recognized that profits on plants producing less than 1,000 gal. of gasoline per day are very uncertain. The overhead expenses, the difficulties of marketing a comparatively small quantity of gasoline, and the fact that these small plants require as much attention as large plants have proved that even under favorable conditions they are not particularly profitable. This is especially true with plants which have been installed to handle a much larger volume of gas than is now available. There are today many plants heavily overequipped with machinery, making the maintenance and depreciation charges on such properties greatly out of proportion to the gasoline produced and the revenue derived.

This condition was largely brought about by overbuilding prior to and during the war. During this time a large number of plants with the intrinsic weakness of insufficient permanent supplies of gas were installed in various parts of the country. The gathering lines of these plants in many instances overlapped the lines of other gasoline plants, so that at present the plant capacity far exceeds the gas now available.

TABLE III COST OF CONSTRUCTING A COMPRESSION PLANT IN 1919-20

Compressors and engines	$33,000	Gathering lines	$50,000
Freight, hauling and setting compressors	10,000	Electrical equipment	1,000
Buildings	5,000	Switch and loading rack (and tankage at loading rack)	15,000
Condensors	5,000	12 mile pipe line to loading rack	40,000
Accumulator tanks	1,000	Water supply	5,000
Auxiliary engine, pumps, etc	3,000		
Storage tanks	25,000		
			$193,000

TABLE IV COST OF CONSTRUCTING AN ABSORPTION PLANT

Absorbers and accessories	$12,000	Railroad switch	$2,000
Pumps	2,000	Buildings	5,000
Compressor (direct connection)	4,000	Boilers	10,000
Still	1,400	Labor	20,000
Oil separator (on gas line)	500	Tools	3,000
Condensor boxes and coils	1,000	Electrical equipment	1,500
Storage tanks	10,000	Grading, draining, ditching	1,000
Loading rack	500	Main lines around plant	5,000
Oil coolers	3,500	Meters, thermostats, and laboratory equipment	500
Heat exchangers	4,500	Building materials	10,000
Site	500	Contingent	10,000
Water supply	3,000		
			$110,900

In the older fields where the gas supply has declined greatly, manufacturers have found that to dismantle many of these plants or to convert them into vacuum or booster stations does not involve a large expenditure. Natural-gas gasoline manufacturers interested in the consolidation of plants and the change of processes have carefully calculated the cost of diverting gas from small to large plants, and of changing the process from compression to absorption, and have found that in most cases it is more profitable to consolidate the plants and change to the absorption process.

The cost of constructing gasoline plants naturally fluctuates according to the cost of material, labor, transportation, etc. The location of the plant, the quality of the gas to be treated, and the capacity of the plant, are factors in determining the cost of installing the plant. If the location of the plant is a considerable distance from a railroad the cost will be appreciably higher. Table III shows the cost of constructing a compression plant in the Appalachian field in 1919 and 1920. This plant could be built at a very much lower cost today. Furthermore, it was built during a period of bad weather, when bad roads were a serious handicap. The plant treats 1,100,000 cu.ft. of natural gas a day and yields as much as 4,500 gal. of gasoline a day.

The cost of labor is included. The cost of operation, including overhead expense, sales, depreciation, interest, depletion and freight is in the neighborhood of 11 cents a gallon.

Production of a plant has little relation to the cost of construction. The cost of installing a plant producing 1 gal. of gasoline to 1,000 cu.ft. of gas would be very little less than for one having a higher production.

An absorption plant having a daily capacity of 20,000,000 cu.ft. of gas and producing about 4,000 gal. of gasoline at high pressure will cost approximately $110,900. This cost is analyzed in detail in Table IV.

It will be noted that this amounts to $27.50 per gal. capacity per day. An absorption plant with a capacity of 1,000 gal. per day would cost about $40,000, and one with a capacity of 10,000 gal. per day would cost from $450,000 to $500,000.

Pressure is an important item in connection with cost. An absorption plant producing 4,000 gal. of natural-gas gasoline per day at 10 lb. pressure would cost from $175,000 to $200,000.

An absorption plant using the charcoal method can be operated successfully regardless of pressure. Such a plant producing 4,000 gal. of gasoline a day would cost approximately $90,000.

The cost of operating an absorption plant having a capacity of 4,000 gal., and costing $110,000 to construct, is as follows:

Interest, 6 per cent	$6,600	Sales expense	5,000
Depreciation, 10 per cent	11,000	Insurance and taxes	3,000
Labor	13,000	Fuel, natural gas at 50 cents per M cu ft	20,000
Repairs and supplies	10,000		
Tank-car rental	7,000		
Administrative expenses	14,000		
			$89,600

This is equal to about 6¼ cents a gallon and may be considered a minimum for operating absorption plants in the Eastern fields.

Welding Pressure Vessels

One of the many difficult problems concerning the boiler code committee of the American Society of Mechanical Engineers in its effort to draw up satisfactory codes governing the construction of unfired pressure vessels was that of welding. Rules applicable to riveted constructions do not always apply to fabrication by welding.

The problem is seriously complicated because of the meagerness of scientific data upon which to base proper requirements for safety without placing unjust restrictions on the use of welding. Wide differences of opinion prevailed not only among the members of the committee, the insurance companies and inspectors, but also in the industry itself.

A hydrostatic and hammer test was finally proposed for determining whether a vessel was safe for the purpose designed. Eight manufacturers placed at the disposal of the committee about forty tanks and enough funds. These tanks have been tested to destruction by the U. S. Bureau of Standards. The shells of most of the tanks were 6 ft. long and 2 ft. in diameter, and made of ⅜-in. mild steel plate. Both electric and oxy-acetylene welding were used. The hydrostatic and hammer test developed that the welded pressure vessel, according to the regular formula for working pressure, has a factor of safety of about 6.

Our Broadening Knowledge of Lubrication

The Recent Chemical and Physical Researches That Have Given Us a Better Insight Into the Composition and Properties of Mineral Lubrication Oils Are Reviewed and the Main Paths for Future Study Are Indicated*

BY A. E. DUNSTAN AND F. B. THOLE
Research Department, Anglo-Persian Oil Co., Ltd., Meadhurst, Sunbury-on-Thames, England

DURING the last few years rapidly increasing attention has been directed by chemists and physicists to the study of lubricating oils. The former have attempted to obtain some knowledge of the various types of hydrocarbons in the oil and their physical and chemical characteristics; the latter have endeavored to elucidate the why and wherefore of lubrication and the most recent researches have tended to develop along the line of contact of the two sections of the investigation.

CHEMICAL COMPOSITION

The chief points so far elucidated regarding the chemistry of mineral lubricating oils are[1]:

(1) It appears beyond doubt that the high-boiling fractions of petroleum, irrespective of their place of origin, are complex mixtures containing but a small percentage of paraffine hydrocarbons of the formula C_nH_{2n+2}, and consisting chiefly of compounds whose formulas range from C_nH_{2n} to C_nH_{2n-8}. A few of these compounds have been isolated by Mabery, by repeated fractional distillation of crude American oils, even from a crude so pronouncedly paraffinoid in nature as Pennsylvania oil.

(2) In no case has the chemical constitution of a component of a lubricating oil been established, but the chemical behavior of these oils indicates that among the components are unsaturated hydrocarbons (possibly open-chain but more probably naphthenic and polynuclear, or perhaps of both types), saturated hydrocarbons (naphthenic and probably to some extent polynuclear, but not to any appreciable extent paraffinoid), and aromatic hydrocarbons (to an unknown and probably a limited extent), together with small amounts of sulphur- and oxygen-containing compounds, the latter of which can be isolated and are probably the principal cause of gumming.

(3) "Unsaturated" compounds constitute between 20 per cent and 40 per cent of most lubricating oils, and are in part removed from the oil by agitation with concentrated sulphuric acid.

CHARACTER OF "UNSATURATED" COMPOUNDS

Brooks and Humphrey have shown that the higher simple olefines are polymerized by concentrated sulphuric acid yielding a colorless condensation product which is insoluble in the acid but soluble in hydrocarbons. Small amounts of carbinols, and acid and neutral sulphates are also produced. It follows, therefore, that the olefine contents of a hydrocarbon mixture cannot be determined volumetrically by extraction with sulphuric acid.

When lubricating oils are shaken with concentrated sulphuric acid, a heavy tarry mass separates which soon becomes solid. It seems doubtful, therefore, if lubricating oils contain more than a small percentage of true olefine hydrocarbons. This conclusion is strengthened by the fact that, so far as our experience goes, attempts to hydrogenate such oils by the Sabatier method have uniformly failed. It would therefore appear that the nature of the unsaturated bodies in lubricating oil is at present an unsolved problem.

A partial separation of these unsaturated hydrocarbons from the saturated ones which does not involve their destruction can be achieved by employing their superior solubility in liquid sulphur dioxide. Thus a lubricating oil with an iodine value of 46 on extraction with liquid sulphur dioxide gave a residue with iodine value 33 and an extract with iodine value 73.

A similar effect can be achieved by filtration through fullers earth, a material which adsorbs unsaturated compounds to a greater degree than saturated compounds. Neither method is sufficiently discriminating to be of use in effecting even an approximate separation of the two types.

The curious iodine value results given by lubricating oils seem to indicate that the unsaturated compounds attacked by sulphuric acid and by formaldehyde do not react readily or normally with iodine.

The reaction of mineral oils toward iodine differs profoundly from that of fatty oils. Experience in the determination of iodine values by means of Wijs' reagent has indicated that by varying the time and proportion of iodine chloride a given mineral lubricating oil may yield widely varying values. For example, a California mineral oil gave a value of 20 in 2 hours, 40 in 4 hours, 60 in 64 hours and 80 in 266 hours, whereas rape oil reached a steady value in 3 minutes. Again, the iodine value of rape oil was found to be practically independent of the amount of Wijs' solution used (provided a fair excess was employed), but with the mineral lubricating oil an increase in the proportion of reagent to oil invariably augments the iodine value.

The interpretation of these results is difficult when coupled with the reluctance exhibited to hydrogenation; unsaturated glycerides of comparable molecular weight behaved quite normally in both respects.

The facts again seem to lead one to the conclusion that the "unsaturated" hydrocarbons in mineral oil consist to a small degree only of true olefines. The sluggish reactivity of the greater part may be due to the somewhat slow and difficult rupture of closed ring systems, which can be brought about by the drastic action of sulphuric acid and Wijs' reagent respectively, whereas the milder action of hydrogen and nickel fails to operate.

NAPHTHENIC, AROMATIC AND RESINOUS COMPOUNDS

(4) Analysis indicates that the residual saturated compounds after treatment with concentrated sulphuric acid are principally naphthenic, and most probably polynuclear in structure, since they contain less hydro-

*A paper presented before the Petroleum Division of the American Chemical Society at Pittsburgh, Sept. 7, 1922.

[1]The present authors have on various occasions (*J. Inst. Pet. Tech.*, 1918, vol. 4, p. 191; British Association, Cardiff, 1920; *J. Inst. Pet. Tech.*, 1921, vol. 7, p. 417; British Association Colloid Committee, Third Annual Report, 1921) discussed the chemical composition of mineral lubricants.

gen than is demanded by the simple naphthenic formula, C_nH_{2n}.

(5) The presence of aromatic hydrocarbons is possible, but has not been definitely proved. By nitration, nitro-derivatives are obtainable; the reduction products from these will, however, not yield azo-dyes, so the nitro-compounds may not be aromatic in type.

(6) Resinous components have been shown by Holde to be present to the extent of a few tenths of a per cent, and to be capable of separation from the hydrocarbons by treatment with alcohol and ether. They are solid, oxygen-containing, lac-like bodies, and are probably an important cause of "gumming," since they would tend to accumulate as the hydrocarbons in the oil evaporated. Moreover, the hydrocarbons thus purified showed no tendency to gum on prolonged exposure to heat and air. Holde's statement would appear to go too far. The removal of these bodies reduced the gumming tendency. Removal of unsaturated hydrocarbons still further reduces it, but even the saturated hydrocarbons oxidize appreciably on exposure to air and heat.

Viscosity and Chemical Character

The actual influence on the viscosity of the oil of the differences in chemical nature of the different components has been stated by several workers, the statements being in some cases contradictory. Mabery and Mathews have published figures which indicate conclusively that an increase in viscosity occurs concurrently with a decrease in the hydrogen content, paraffines being comparatively very mobile and inefficient in lubricating powers, while hydrocarbons of the formula C_nH_{2n-4} are said to be as viscous and as efficient as sperm oil.

It is a well known fact that paraffines are comparatively poor lubricants, while oils such as medicinal paraffine and vaseline, which have been submitted to vigorous refining by acid or filtration generally with the object of decolorizing, are inferior in viscosity and in lubricating efficiency to those which still contain a certain proportion of unsaturated hydrocarbons. The oil refiner should therefore carefully regulate the treatment given so as to remove as far as possible the oxygenated compounds and the more highly reactive of the unsaturated hydrocarbons, which are chiefly responsible for gumming and carbonization, while destroying only a minimum of those more stable unsaturated hydrocarbons the presence of which in the oil is an asset.

Krämer and Spilker have synthesized condensation products from methylated benzenes and alkyl alcohol, which possess extremely high viscosity, and are in fact synthetic lubricating oils. For example, with mesitylene as a starting-out material, they have made:

$$(CH_3)_3C_6H_2-\underset{\displaystyle CH_3}{\overset{\displaystyle CH_3}{\underset{|}{\overset{|}{C}}}}-C_6H_2(CH_3)_3 \text{ or } C_{21}H_{28}\text{; i.e., } C_nH_{2n-14}$$

This compound has a specific viscosity of over 700. They consider that such bodies are the true "viscosity carriers" in lubricating oil and that the high viscosity is due to the accumulation of methyl groups.

R. H. Brownlee has recently shown that a hydrocarbon oil of high flash point and viscosity and very low cold test, suitable for lubrication, is obtained by the polymerization of light unsaturated hydrocarbons by agitating them with a catalyst preferably at 200 to 400 deg. F. As catalysts anhydrous aluminum chloride, or a halide or reagents which produce a halide in the nascent state, are used. The oil, after treatment, is washed and distilled with steam. The distillates include products having the flash points of naphtha and kerosene, and a variety of lubricating oil fractions.

(8) The influence of physical conditions on the viscosity of lubricating oils, especially as regards preliminary heat-treatment, was pointed out long ago by Bender, while the recognition of colloidal components in machine oil by Schneider and Just brought lubricating oils into line with other colloids as regards the well-known manifestation of temperature-viscosity hysteresis. Heavy mineral oils must undoubtedly be iso-colloids—i.e., polyphase systems in which the dispersed component is of the same chemical nature as the dispersion medium. Just as water must be regarded as a system in which molecules such as $(H_2O)_n$ coexist with simple H_2O molecules, so in a lubricating oil the disperse phase is a molecular aggregate suspended in a dispersion medium of simpler and similar structure.

The Property of "Oiliness"

(9) The vital importance of maintaining the film of lubricant between shaft and bearing necessitates that mysterious property known as "body." Perhaps no property has been discussed so assiduously among lubrication experts as this. Archbutt and Deeley refer to this as "oiliness" and indorse the opinion of Wilson that, in reality, oiliness or body is a function both of viscosity and of capillarity. Unfortunately there is little experimental record on the surface tension of mineral oils, but there is a very close relationship between the two properties to which reference has been made. Both are conditioned by the play of intermolecular forces, and both are intimately affected by association and unsaturation.

It is not improbable that some connection exists between body and molecular weight. When it is realized that the triglycerylester of ricinoleic acid, which is present in castor oil, has a molecular weight of 932, whereas that of Russian engine oil is 426, it is reasonable to expect a much higher value for the molecular volume in the fatty oil. This enhanced value shows itself not only in high viscosity but also in "oiliness."

Granted that lubricating oils are iso-colloids, it is possible that this mysterious oiliness or body may be dependent on the degree of dispersion exhibited by the particular oil.

In recent years the property of "oiliness" has become associated with the presence of unsaturated compounds which constitute 20 to 40 per cent of most lubricating oils.

W. B. Hardy concludes that lubrication depends wholly on the chemical constitution of a fluid; the fact that the true lubricant is able to render slipping easy when a film of only about one molecule deep is present on the solid faces suggests that the true lubricant is always a fluid which is adsorbed on the solid face, such adsorption being dependent on the attractive forces associated with unsaturated compounds. It follows that lubrication is merely a special problem of colloid physics. A surface saturated with a film of condensed matter (ordinary glass, for example, possesses a film of grease on the surface with a depth of $1\mu\mu$) differs from one with a cleaned or raw surface. The surface of water after scraping has a higher surface tension and is highly adsorptive. Vigorous rubbing of a glass surface under water with the finger tips until a clinging feel is produced yields a fresh surface which possesses peculiar

properties such as "seizing" when in contact with a similar fresh surface.

Deeley has measured static co-efficients of various oils between metals. When no lubricant is used the static co-efficient increases as the surfaces continue to rub against each other. Such clean surfaces are very sensitive to contamination influences—e.g., moisture. It is interesting to note that the oils which have the smallest coefficient of friction are those which have proved the best lubricants in practice. It would appear that the unsaturated molecules of the lubricant enter into a firm physicochemical union with the metallic surfaces, forming a friction surface which is a compound of oil and metal. This surface would also appear to be of more than molecular thickness. Thin films of this kind cannot be removed by merely wiping, but must be ground off under water, or a thin layer of metal must be cut off.

Fatty Acid Blending

H. M. Wells and J. E. Southcombe consider that the superiority of a blended or compounded oil is due to the presence of a small amount of free fatty acid, either pre-existing in the added saponifiable oil or formed therefrom by hydrolysis. They therefore propose to prepare lubricating oils by adding to mineral oils such a quantity as 1 to 2 per cent of free fatty acid. Acids of low molecular weight such as butyric and cinnamic acids results in the formation of a non-emulsifiable oil, while the acids of high molecular weight like those obtained from whale oil, wool grease, etc., form emulsifiable oils suitable for marine lubrication.

During the past year these workers have continued the development of their views on the influence of small amounts of fatty acids when dissolved in mineral oils. They emphasize the distinction between the lubrication of fast running shafts with a large excess of oil, where the frictional values are a function primarily of the oil viscosity, and that of slow speed machinery with high bearing pressure, where viscosity measurements no longer assist in the choice of the lubricant. They have found that the interfacial tension against water of vegetable and animal oils was very much lower than that of a mineral oil, and this lowering was due to the slight content of free fatty acid in the fatty oils; by removing the free fatty acids from the saponifiable oils the tension rises, and by adding free fatty acids to the mineral oil the tension can be lowered. It follows that if a substance be added to an oil which brings about a lowering of interfacial tension, such addition will act favorably as far as lubrication is concerned by preventing a rupture of the liquid film and consequent direct contact between the metals.
